US Army Corps of Engineers
Kansas City District

Final (Revised) Data Gap Evaluation Technical Memorandum

Remedial Investigation/ Feasibility Study
Raritan Bay Slag Superfund Site
Old Bridge/ Sayreville, New Jersey

USACE Contract No. W912DQ-08-D-0018
Task Order No. 018

June 2010

R2-0000056

Contents

Section 1 Introduction

1.1 Purpose of the Technical Memorandum 1-1
1.2 Technical Memorandum Organization 1-1
1.3 Site Description 1-1
1.3.1 Site Location 1-1
1.3.2 Key Site Features 1-2
1.3.3 Contaminant Sources 1-2
1.4 Environmental Setting 1-3
1.4.1 Topography and Drainage 1-3
1.4.2 Geology and Hydrogeology 1-4
1.4.3 Surface Water 1-5
1.5 Investigation Areas 1-5

Section 2 Data Evaluation

2.1 Database Development 2-1
2.2 Data Quality and Reporting 2-1
2.3 Screening Criteria 2-2
2.3.1 Screening Criteria for Sediment 2-3
2.3.2 Screening Criteria for Soils 2-3
2.3.3 Screening Criteria for Surface Water and Pore Water 2-3
2.3.4 Screening Criteria for Groundwater 2-3
2.3.5 Background 2-4
2.4 Indicator Contaminants 2-4
2.5 Organic Contaminants 2-5

Section 3 Summary of Historical Data

3.1 Introduction 3-1
3.2 NJDEP Preliminary Site Investigation, April 2007 (March 2007 Sampling Results) 3-3
3.2.1 Description 3-3
3.2.2 Findings 3-3
3.2.2.1 Preliminary Assessment 3-3
3.2.2.2 March 2007 Soil Sampling Results 3-4
3.3 NJDEP Sampling Event, May 2007 (May 2007 Sampling Results) 3-4
3.3.1 Description 3-4
3.3.2 Findings 3-4
3.4 NJDEP Sampling Event, July 2007 (July 2007 Sampling Results) 3-5
3.4.1 Description 3-5
3.4.2 Findings 3-5
3.5 OBMUA Limited Site Investigation Report and Remedial Action Work Plan, August 2007 (May 2007 Sampling Results) 3-5
3.5.1 Description 3-5
3.5.2 Findings 3-6
3.5.3 Remedial Action Selection 3-7
3.6 OBMUA Remedial Action Report, April 2008 (October 2007 to February 2008 Sampling Results) 3-7

3.6.1 Description ... 3-7
3.6.2 Findings ... 3-8
3.7 EPA Summary Letter Report, Phase I Investigation, January 2009 (September 2008 Sampling Results) ... 3-8
3.7.1 Description ... 3-8
3.7.2 Findings ... 3-9
3.7.2.1 Area 1: Laurence Harbor Seawall ... 3-9
3.7.2.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty) ... 3-9
3.7.2.3 Area 3: Laurence Harbor Playground ... 3-10
3.7.2.4 Area 4: Old Bridge Waterfront Park (Walking Park Parallel to Seawall) ... 3-10
3.7.2.5 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty) ... 3-10
3.7.2.6 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty) ... 3-10
3.7.2.7 Area 7: Cheesequake Creek Inlet ... 3-10
3.7.2.8 Area 8: Cheesequake Creek Inlet Western Jetty ... 3-11
3.7.2.9 Area 9: Margaret's Creek ... 3-11
3.7.2.10 Background ... 3-11
3.8 EPA Hazard Ranking System Documentation Record, Raritan Slag, April 2009 ... 3-12
3.8.1 Description ... 3-12
3.8.2 Findings ... 3-12
3.9 EPA Summary Letter Report, Phase II Investigation, June 2009 (April 2009 Sampling Results) ... 3-13
3.9.1 Description ... 3-13
3.9.2 Findings ... 3-14
3.9.2.1 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty) ... 3-14
3.9.2.2 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty) ... 3-14
3.9.2.3 Area 9: Margaret's Creek ... 3-14
3.9.2.4 Background ... 3-15
3.10 EPA Chemical Assessment Report, Raritan Bay Slag Site, June 2009 (September 2008 Sampling Results) ... 3-15
3.10.1 Description ... 3-15
3.10.2 Findings – Chemical Assessment Report, June 2009 ... 3-16
3.10.2.1 Area 1: Laurence Harbor Seawall ... 3-16
3.10.2.2 Area 8: Cheesequake Creek Inlet Western Jetty ... 3-18
3.11 EPA Trip Report: Raritan Bay Sediment Sampling, August 2009 (June to July 2009 Sampling Results) ... 3-19
3.11.1 Description ... 3-19
3.11.2 Findings ... 3-19
3.11.2.1 Area 1: Laurence Harbor Seawall ... 3-19
3.11.2.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty) ... 3-19
3.11.2.3 Area 3: Laurence Harbor Playground ... 3-19
3.11.2.4 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty) ... 3-20
3.11.2.5 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern ...

Inlet Jetty) 3-20
3.11.2.6 Area 7: Cheesequake Creek Inlet 3-20
3.11.2.7 Area 8: Cheesequake Creek Inlet Western Jetty 3-20
3.12 Additional Information 3-20
3.12.1 EPA Aerial Photography 1957 to 2008 3-20
3.12.1.1 Cheesequake Creek and West Jetty Inlet Aerials 3-20
3.12.1.2 Laurence Harbor Seawall and Margaret's Creek (previously called Marquis Creek) 3-21
3.12.2 Regional Environmental Monitoring and Assessment Program, 2003 3-21
3.12.3 OBMUA Phase IA Cultural Resources Survey, February 2005 3-22
3.12.3.1 Documentary Research 3-22
3.12.3.2 Site Visit 3-22
3.12.3.3 Soil Borings 3-23
3.12.4 OBMUA Phase IB Cultural Resources Survey, April 2005 3-23
3.12.4.1 Documentary Research 3-23
3.12.4.2 Archaeological Testing at Systematic Intervals 3-23
3.12.5 OBMUA Geotechnical and Hydrogeological Information, April 2007 3-23
3.12.5.1 Geotechnical Investigation 3-23
3.12.5.2 Hydrogeological Investigation 3-24
3.12.6 ATSDR Health Consultation, Raritan Bay Slag Site, February 2009 3-24
3.12.6.1 Area 1: Laurence Harbor Seawall 3-25
3.12.6.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty) 3-25
3.12.6.3 Area 3: Laurence Harbor Playground 3-26
3.12.6.4 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty) 3-26
3.12.6.5 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty) 3-26
3.12.6.6 Area 8: Cheesequake Creek Inlet Western Jetty 3-27
3.12.6.7 ATSDR Recommendations 3-27
3.12.7 EPA Side-Scan Sonar and Diver Investigation Survey Letter Report, June 2009 3-28
3.12.7.1 Results of the Side Scan Survey and Diver Investigations 3-28
3.12.7.2 Results of the Sediment Sample Analysis 3-29

Section 1
Introduction

Under the United States Army Corps of Engineers (USACE), Kansas City District, Contract No. W912DQ-08-D-0018, Task Order No. 018, CDM Federal Programs Corporation (CDM) has been tasked to provide technical services to complete a Remedial Investigation/Feasibility Study (RI/FS) for the Raritan Bay Slag Superfund Site (the site) located in Old Bridge and Sayreville, Middlesex County, New Jersey. As an initial step in the RI/FS, CDM was tasked to prepare this technical memorandum to identify gaps in the existing data.

1.1 Purpose of the Technical Memorandum

The overall goal is to ensure that there is sufficient data to support the RI, FS, human health risk assessment, and ecological risk assessment.

The key goals of this technical memorandum are as follows:

- Summarize existing data provided by the USACE
- Identify gaps in the existing data
- Provide recommendations to fill the data gaps

1.2 Technical Memorandum Organization

This Technical Memorandum is organized in the following manner:

Section 1 Introduction - presents an overview of the site including the environmental setting and a summary of activities that have occurred at the site to date.

Section 2 Data Evaluation– describes the overall approach and provides the screening criteria used to evaluate the existing data

Section 3 Summary of Historical Data – Summarizes the existing data collected from the site and presents findings and conclusion of various historical reports.

Section 4 Data Gap Evaluation and Recommendations – Evaluates gaps in the existing data by Site Area and provides recommendations to fill the data gaps.

Section 5 References

1.3 Site Description

This section provides an overview of the Raritan Bay Slag site including the site location, a description of key site features, and a summary of contaminant sources.

1.3.1 Site Location

The site is located on the shore of Raritan Bay, in the eastern part of Old Bridge

Township within the Laurence Harbor section in Middlesex County, New Jersey. Raritan Bay is also referred to as Raritan-Sandy Hook Bay, but will be referred to as Raritan Bay throughout this document. A small portion of the northern end of the site, the western jetty at the Cheesequake Creek Inlet, is located in the Borough of Sayreville. The site is situated in a residential area on Raritan Bay in New Jersey and is bordered to the east and west by residential properties; immediately to the south by State Highway 35 with residential properties beyond the highway; and to the north by Raritan Bay. Figure 1-1 provides a site map and shows the location of the site.

1.3.2 Key Site Features

The site is approximately 1.5 miles in length and consists of the waterfront area between Margaret's Creek (also known as Marquis Creek on some maps) and the area just beyond the western jetty at the Cheesequake Creek Inlet. The site also includes the wetland areas connected to Margaret's Creek. The portion of the site located in Old Bridge contains the Old Bridge Waterfront Park. The park is made up of walking paths, a playground area, several public beaches, and three jetties, not including the two jetties at the Cheesequake Creek Inlet. The park waterfront is protected by a seawall.

1.3.3 Contaminant Sources

Slag from lead smelting and recovery operations is present in two source areas at the site: the Cheesequake Creek western jetty and the seawall. These source areas were identified in EPA's Hazard Ranking System Report (HRS) (EPA, 2009) and have been the subject of numerous investigations, which are summarized in Section 3.

Slag from lead smelting and recovery operations was placed at the site approximately 40 years ago. The seawall is partially constructed with pieces of slag while the western jetty at the Cheesequake Creek Inlet and the adjoining waterfront area west of the jetty also contain slag. Analysis of the slag indicates the presence of high concentrations of metals including lead, arsenic, antimony, copper, and chromium. Leaching tests performed by the Environmental Protection Agency's (EPA's) Emergency Response Team (ERT) indicate that metals leach from the slag under environmental conditions.

In September 1972, the New Jersey Department of Environmental Protection (NJDEP) was advised by a local environmental commission member that lead-bearing waste material was being deposited along the Laurence Harbor beachfront. The material was reported to be non-recoverable, low-yield metallic waste from a blast furnace and blast furnace rubble. The slag was deposited at the beachfront in the late 1960s and early 1970s, mostly in the form of kettle bottoms, in an area that had sustained significant beach erosion and damage due to a series of storms in the 1960s. Demolition debris in the form of concrete and a variety of bricks, including fire bricks, was also placed along the beachfront. A portion of the seawall also contains large riprap believed to have been placed over the slag when the grassed and paved portion of the park was developed.

The western jetty at Cheesequake Creek Inlet has been in existence since the USACE constructed it in the late nineteenth century. The slag was reportedly placed on the jetty during the same general time period as the construction of the seawall. The entire

jetty is covered with slag that is similar in appearance to the slag on the seawall. The waste material and slag were used to supplement the jetty and were used as fill and stabilizing material for the seawall.

Other potential sources of contamination at the site include fill material in the Margaret's Creek area and fill material in the park area adjoining the seawall (Areas 1 and 4).

In May 2007, elevated concentrations of metals including lead, arsenic, antimony, and chromium were detected fill material soil samples collected from the Margaret's Creek area (Area 9) during a site investigation performed in connection with construction of an interceptor sewer for the Old Bridge Municipal Utilities Authority (OBMUA) (OBMUA 2007). However, the site investigation was limited to the 40-foot wide sanitary sewer easement that crosses the Margaret's Creek area. Contaminated soils within a portion of the construction easement were removed during the construction activities. However, the remaining fill potentially is a source of contamination to Margaret's Creek and the associated wetlands. The previous site investigation and cleanup activities conducted in the Margaret's Creek area are described in Sections 3.5 and 3.6.

The park area adjoining the seawall (Figure 1-2) may contain fill material placed in connection with construction of the seawall or during construction of the paved and grassed park areas. A surface geophysical investigation performed in spring 2009, identified a number of subsurface anomalies and concluded that fill materials may be buried in this area. Test excavations are planned for the park area adjoining the seawall to uncover and characterize any buried fill material and to collect samples for chemical analysis. Test excavation activities are schedule to begin in April 2010.

The site has been the subject of numerous environmental investigations and remediation work dating back to 2006. Widespread metals contamination has been observed in soil, sediment, and surface water during multiple site investigations performed by or on behalf of both NJDEP in 2006 and 2007and EPA in 2008 and 2009.

1.4 Environmental Setting

1.4.1 Topography and Drainage

As shown on Figure 1-1 the site is located along Raritan Bay between the Cheesequake Inlet on the west and Margaret's Creek to the east. This map also shows site topography which varies from a maximum of 40 feet just south of Margaret's Creek and 50 feet just west of Cheesequake Creek to essentially sea level along the beach where the Site Areas shown on the map are located. Beach topography varies with the season in response to storms and wave action. During the summer the beach profile is typically relatively flat and is steeper during the winter.

Surface water drainage in the vicinity of the site is toward Cheesequake Creek, Flat Creek, or Stump Creek, and their associate wetlands, or towards Margaret's Creek and its associated wetland. Surface drainage at the site itself and in the Site Areas shown

on Figure 1-1 is toward Raritan Bay, or in the case of Areas 4 and 9, directly toward the bay and toward Margaret's Creek and its associated wetland.

1.4.2 Geology and Hydrogeology

This section provides an overview of the geology and hydrogeology in the vicinity of the site based on review of available information.

Geology

Figure 1-2 shows the surficial geologic map of the Raritan Bay site and vicinity and the location of the two known slag source areas. The site is underlain primarily by Quaternary age beach deposits (Qbs) which are up to 15 feet thick. Off shore, the site is underlain by Quaternary age estuarine deposits (Qmm) consisting of organic clay and silt, peat, and sand and gravel. These same estuarine deposits underlie Cheesequake Creek, Margaret's Creek and their associated wetlands. In the vicinity of the site the estuarine deposits are at least 50 feet thick underlying Cheesequake Creek where regional mapping shows that the top of the Cretaceous age Magothy Formation is at an elevation of –50 feet mean sea level (msl). Developed areas, where houses and business are located, are underlain by weathered coastal plain sediments (Qwcp), consisting of sand, silt, and clay, or Upper Terrace Deposits (Qtu) which consist of sand, gravel, minor silt and are up to 20 feet thick. The surficial deposits described above are underlain by the Cretaceous-age Magothy Formation. The Magothy Formation is extensive in outcrop and in the subsurface throughout the Coastal Plain of New Jersey and adjacent states. On a regional basis, the formations are part of a major Coastal Plain aquifer system known as the Potomac-Raritan-Magothy (PRM). The PRM system consists of lower, middle, and upper aquifers that are separated by confining units. Only the middle and upper aquifers and their intervening confining unit are present in Middlesex County. In the vicinity of the site the Magothy Formation is underlain by bedrock at a depth of about 500 feet below the ground surface (bgs).

Hydrogeology

As illustrated in Figure 1-3, the Raritan Bay site is an area of extensive interaction between surface water and groundwater. This figure shows that the site is bordered to the south by the predominantly saline wetlands associated with Cheesequake Creek and Margaret's Creek. Regionally, groundwater flow in the Magothy Formation would be expected to be from the west to the east and to discharge into Raritan Bay. No site-wide water level data are available at the present time but shallow groundwater flow in the surficial Quaternary age deposits is expected to be predominantly toward the nearest surface water body which might be a creek, a wetland, or the bay. Close to the Site Areas groundwater would be expected to flow toward the bay. There should also be an upward vertical gradient close to the bay as groundwater discharges to the bay. Groundwater levels in the surficial deposits should be influenced by tidal fluctuations in Raritan Bay, Cheesequake Creek, and Margaret's Creek. The influence will be greatest close to the bay and creeks and will dissipate with distance.

1.4.3 Surface Water

Major surface water bodies in the vicinity of the site include Raritan Bay, Cheesequake Creek, and Margaret's Creek. Figures 1-1 and 1-3 show the surface water bodies in the vicinity of the site.

Raritan Bay

The Raritan Bay is a large embayment, approximately 109 square miles in area, bordering the states of New York and New Jersey. Raritan Bay receives input from the Raritan River, Shrewsbury and Navesink Rivers (via Sandy Hook Bay), and numerous smaller streams along the shorelines of the bay. Raritan Bay also receives input from the Hudson River via the lower New York Harbor and from the Passaic and Hackensack Rivers via Newark Bay and the Arthur Kill. With the exception of navigation channels, water depths in the bay are relatively shallow, often less than 20 feet deep. The average tidal range in the bay is 5.5 feet. The mixing of marine and fresh waters within the bay results in large fluctuations in salinity, temperature, and dissolved oxygen. Sediments in the bay are predominantly sand, with areas of gravelly sand overlain by silt and very fine sand (U.S. Fish and Wildlife Service [USFWS], 1997).

The Raritan Bay and adjoining terrestrial habitats support the rich and diverse ecological resources characteristic of estuarine environments. Over 90 species of fish and 205 species of emphasis, including threatened and endangered species, occur in Raritan Bay. It is estimated that over 60,000 shore birds visit the Raritan Bay area each year (USFWS Undated).

Cheesequake Creek

Cheesequake Creek is a tidal creek that drains tidal wetlands located southwest of the creek outlet and discharges to Raritan Bay between two jetties referred to as the Cheesequake Creek western and eastern jetties. The Cheesequake Creek western jetty has been augmented with slag that is visible on the surface. Side scan sonar of the creek bed between the two jetties and visual observations by EPA divers indicate that sediment in the creek is primarily gravel. Stream flow records for Cheesequake Creek were not available from the United States Geological Survey (USGS).

Margaret's Creek

Margaret's Creek is a small tidal stream that drains a wetland near the eastern border of the site and discharges directly to Raritan Bay. The creek is located just east of a seawall that has visible slag. Metals contamination has also been observed in the soils of the wetland that are drained by the creek. Field observations during the site visit by CDM indicate that the stream has a sandy bed near its outlet to Raritan Bay. At the time of the site visit, stream flow was very low. It is likely that stream flow in Margaret's Creek fluctuates widely in response to precipitation events and storm surges. Stream flow data were not available from USGS.

1.5 Investigation Areas

The site has been divided into 11 Site Areas based on areas identified in historical investigations and reports, site physical characteristics, and the locations of known or

potential sources. Figure 1-2 shows the Site Areas. Initially, a total of nine Site Areas were identified. However, Site Areas 10 and 11 were added for the following reasons:

- Area 10 is a sediment background location.
- Area 11 was defined because previous reports recommended additional sampling in depositional areas associated with Areas 7 and 8.

The 11 Site Areas are defined as follows:

Area 1: Laurence Harbor Seawall - the seawall along Old Bridge Waterfront Park west of Margaret's Creek to the beach area at the foot of Laurence Parkway.

Area 2: Laurence Harbor Beach - the beach area at the foot of Laurence Parkway between the western end of the seawall and the first jetty.

Area 3: Laurence Harbor Playground - the park playground adjacent to the western end of the seawall.

Area 4: Old Bridge Waterfront Park - the park area along the seawall (not including the playground) from the fence to the roadway.

Area 5: Laurence Harbor Beach - the beach area between the first and third jetty.

Area 6: Laurence Harbor Beach - the beach area between the third jetty and Cheesequake Creek Inlet eastern jetty.

Area 7: Cheesequake Creek Inlet - the inlet between the eastern and western jetties from the jetty points to Route 35.

Area 8: Cheesequake Creek Inlet Western Jetty - the jetty west of the inlet in Sayreville

Area 9: Margaret's Creek - the wetlands associated with the Creek (between the beach and Route 35), including the adjacent beach (east of the Creek to the Middlesex County Pumping Station).

Area 10: Background Area – the historical background sampling location.

Area 11: Depositional Areas – the potential depositional areas associated with Areas 7 and 8.

The summary of historical data presented in Section 3 reflects the 11 Site Areas as currently configured. The evaluation of data gaps and recommendations provided in Section 4 were prepared for each of the 11 areas.

Section 2
Data Evaluation

This section discusses the approach to evaluation of existing data for the site and identifies the criteria used to screen the data to identify data gaps.

2.1 Database Development

To facilitate evaluation and presentation of a large amount of existing data collected by multiple entities, CDM uploaded the data into the EQuIS database. EQuIS is an environmental data management and reporting platform that interfaces with industry standard data reporting, spatial analysis, and data evaluation software. Analytical and location data provided in electronic data deliverables (EDDs) were uploaded directly into the database. A subset of the data was not in electronic format and was input manually. Quality Control (QC) checks were performed on 100% of the data that were entered manually. Approximately 1,600 sample results were uploaded into the EQuIS database. The database was used to facilitate evaluation, reporting, and visualization of the data. The data were grouped by site-specific areas, media, and in the case of sediment and soil data, by depth. Data are presented and evaluated for 11 separate Site Areas.

After uploading was complete, the analytical data were checked for completeness and to ensure that all of the associated data fields such as depth, location, and media type were fully populated. In some cases, data such as depth, location, and media type were missing or incorrect. Location data was checked against the location information provided in the Geographic Information System (GIS) and corrected, if necessary. Information on media type and sample depth was obtained from existing reports. In some instances, media type was assigned based on sample locations depicted in the GIS.

To support evaluation of the existing data by Site Area, GIS was used to assign an area attribute to all of the records in the database. The area attribute was used to support the various queries required to screen the data by Site Area. In addition, multiple data files in the existing GIS were consolidated to support effective retrieval and graphical presentation of spatial data. GIS was used to develop graphics to support evaluation of analytical data.

2.2 Data Quality and Reporting

No assessment was made of the quality of the data used in this technical memorandum. With the exception of data obtained from the OBMUA for Area 9, all data used in this technical memorandum were generated by EPA contractors using EPA laboratory resources including EPA's Contract Laboratory Program (CLP), EPA's Region 2 Division of Environmental Science and Assessment (DESA) laboratory, and EPA's ERT laboratory. These laboratories operate in accordance with EPA's quality assurance/quality control (QA/QC) program requirements. EPA contractors released the data in various reports and, therefore, it is assumed that the data were validated for use in reporting.

The quality of OBMUA data for Area 9 was not assessed or validated because the laboratory data packages were not available. These data cover a limited area and were collected and analyzed under the auspices of NJDEP.

Review of the existing data indicated that some data were rejected. Data qualified as "rejected" (R) were not used in this technical memorandum. All of the remaining data, including data qualified as "estimated" (J), are considered to be valid and were used to support evaluation of data gaps.

Analytical data presented in this technical memorandum are reported in units consistent with the standard data reporting units used by EPA's CLP laboratory and are as follows:

- Organic and inorganic data for aqueous samples are presented in micrograms per liter (µg/L).
- Organic data for solid samples (i.e., soils and sediments) are presented in micrograms per kilogram (µg/kg).
- Inorganic data for solid samples are presented in milligram per kilogram (mg/kg).

2.3 Screening Criteria

To support evaluation of gaps in the existing data, screening criteria were selected to evaluate contaminants detected in site media. Whenever possible, established regulatory criteria, known as chemical-specific applicable or relevant and appropriate requirements (ARARs), were used for the screening criteria values. In addition to ARARs, regulatory guidance values, known as "to be considered" (TBC), were also used.

The screening criteria for sediment, surface water/pore water, soil, and groundwater are provided in Tables 2-1 through 2-4. Since multiple screening criteria were identified for each environmental medium, to be conservative, the lowest value was used to screen the data.

Samples were categorized by media for screening (e.g., soil, sediment, surface water). In most instances, the media designation provided in the existing data report was used. However, in some instances it was apparent that samples that were clearly sediment samples based on their location were designated as soil samples in the electronic data files. The media type was adjusted accordingly based on a review of the locations of the sample in the GIS.

The screening criteria in tables 2-1 through 2-4 were compiled for the purpose for evaluating the existing data. These screening criteria will be revised and updated during the course of the RI based on input from the USACE and stakeholders.

Screening criteria were compiled from various sources as described below.

2.3.1 Screening Criteria for Sediment

Sediment screening criteria were compiled from the following sources.

- EPA Regional Screening Level (RSL) for residential soil, based on cancer risk of 1×10^{-6} and non-cancer hazard index of 0.1 (EPA 2009).
- NJDEP Ecological Screening Criteria (NJDEP 2009 http://www.nj.gov/dep/srp/guidance/ecoscreening/).
- National Oceanic and Atmospheric Administration (NOAA) Screening Quick Reference Tables, Office of Response and Restoration Division (NOAA 2008).
- EPA Region 3 Biological Technical Assistance Group (BTAG) Marine Sediment Screening Benchmarks, Mid-Atlantic Risk Assessment: Ecological Risk Assessment (EPA 2006).

2.3.2 Screening Criteria for Soils

Screening criteria for soils were compiled from the following sources.

- NJDEP Residential Direct Contact Health Based Criteria and Soil Remediation Standards (NJDEP 2008)
- NJDEP Non-Residential Direct Contact Health Based Criteria and Soil Remediation (NJDEP 2008)
- NJDEP Guidance Document, Development of Site-Specific Impact to Groundwater Soil Remediation Standards Using the Soil-Water Partition Equation (NJDEP 2008)
- Ambient Levels of Metals in New Jersey Soils (NJDEP 2003)
- EPA RSL for residential soil, based on cancer risk of 1×10^{-6} and non-cancer hazard index of 0.1 (EPA 2009)
- EPA Ecological Soil Screening Levels (EcoSSLs)
- Efroymson, R.A., G.W. Suter II, B.E. Sample, and D.S. Jones. Preliminary Remediation Goals (PRGs) for Ecological Endpoints. Prepared for the Department of Energy (DOE) (1997)
- EPA Region 5 Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels (EPA 2003)

2.3.3 Screening Criteria for Surface Water and Pore Water

Surface waters/pore water screening criteria were compiled from the following sources.

- NJDEP Surface Water Quality Standards, Saline Water, Chronic Values (NJDEP 2009)
- National Recommended Water Quality Criteria (NRWQC), Saltwater Criterion, Continuous Concentrations (EPA 2009)
- EPA 2006. EPA Region 3 BTAG Marine Screening Benchmarks. Mid-Atlantic Risk Assessment: Ecological Risk Assessment, (EPA 2006)

2.3.4 Screening Criteria for Groundwater

Groundwater screening criteria were compiled from the following sources.

- New Jersey Ground Water Quality Standards Class IIA (NJAC 7:9C) (NJDEP 2008)
- EPA National Primary Drinking Water Standards (maximum contaminant levels [MCLs], EPA 816-F-03-016 (EPA 2003)
- New Jersey Drinking Water Standards (NJDEP 2005)

- EPA RSL for tap water, based on cancer risk of 1×10^{-6} and non-cancer hazard index of 0.1 (EPA 2009)

2.3.5 Background

Background values were not developed in this technical memorandum and the existing data were not screened against background concentrations. Information in the Regional Environmental Monitoring Assessment Program (REMAP) report (EPA 2003), a bay-wide study of contaminant levels in Raritan Bay, will be assessed before the work plan is completed and may be used to support development of representative background levels for sediments for use in the RI report. Limited background data for sediment and surface water are included in the existing data. Section 4 includes recommendations for establishing background concentrations for the site media that will be investigated during the RI.

2.4 Indicator Contaminants

To provide a focused and coherent assessment of the large quantity of existing analytical data, CDM reviewed existing documents and data to identity contaminants that could be used as indicator contaminants. Previous reports used a similar approach, although the contaminants that were used as indicators varied among the reports and included lead, arsenic, antimony, copper, chromium and other metals. These metals or metalloids (arsenic) were known to be associated with the slag. In leaching tests and slag composition tests, lead was typically present at concentration orders of magnitude greater than any of the other metals present in the slag (Lockheed Martin 2009). Although other metals were found in varying but lower proportions in slag relative to lead, arsenic was considered to be a good indicator contaminant because of its generally higher water solubility. This characteristic of arsenic makes it suitable as an indicator contaminant since it represents a greater ability to migrate in environmental media than lead.

Although all data were screened against site-specific screening criteria and are presented in this memorandum (Appendix A), two metals, lead and arsenic, were selected as indicator contaminants. This approach was used to evaluate the existing sediment, surface water, pore water, and soil sampling data. In addition to the considerations above related to the characteristics of lead and arsenic in the slag source material, the following information was also considered in the selection of indicator contaminants.

- The frequency and magnitude of lead and arsenic in samples that exceeded screening criteria
- The occurrence of other metals including antimony, copper, and chromium, along with lead and arsenic in the samples

The evaluation of data gaps is focused on the extent and spatial distribution of lead and arsenic concentrations that exceed applicable screening criteria in site media. Appendix A includes tables comparing all sampling results against the selected media-specific screening criteria. Figures 4-2 through 4-39 in Section 4 show the

distribution of lead and arsenic concentrations exceeding screening criteria in sediment, surface water, pore water, and soil samples.

2.5 Organic Contaminants

Thirty-five sediment and 14 soil samples collected during previous investigations were analyzed for organic contaminants including volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), pesticides, and polychlorinated biphenyls (PCBs). Organic compounds were screened against the media-specific screening criteria presented in Section 2.3. Organic compounds that exceeded screening criteria are provided in Appendix A and are discussed in Section 4.2.6 Organic Contaminants.

Section 3
Summary of Historical Data

The following sections provide a summary of the historical data that were reviewed as part of the data gap evaluation. The data were reviewed and are presented by Site Area. The Site Areas covered in each report are described in each section.

3.1 Introduction

As discussed in Section 1, the site has been the subject of numerous environmental activities dating back to 2004. The historical data that were reviewed to prepare this Technical Memorandum include the following:

- Regional Environmental Monitoring Assessment Program (EPA 2003).
- Phase IA Cultural Resources Survey, Laurence Harbor Interceptor, Old Bridge Township, Middlesex County, New Jersey (February 2005) prepared by Richard Grubb & Associates, Inc., Cultural Resource Consultants.
- Phase IB Cultural Resources Survey, Laurence Harbor Interceptor, Old Bridge Township, Middlesex County, New Jersey (April 2005) prepared by Richard Grubb & Associates, Inc., Cultural Resource Consultants.
- Site Investigation Report for Old Bridge Township – Margarets Creek Property, Old Bridge Township, Middlesex County (April 2007) prepared by NJDEP.
- Specifications, Drawings, Proposal and Contract Documents for Old Bridge Municipal Utilities Authority, Laurence Harbor Interceptor, Middlesex County, NJ, Contract No. 2005-1 Rebid, Geotechnical and Hydrogeological Information (April 2007) prepared by R3M Engineering, Inc.
- Memorandum, Laurence Harbor Seawall, Engagement of Laboratory Services Contract A57425 (May 19, 2007) prepared by NJDEP's Environmental Measurements Section.
- Memorandum, Margaret's Creek Lead Contamination – A4639300, Soil Sampling – July 24, 2007 (August 6, 2007) prepared by NJDEP's Environmental Measurements Section.
- Memorandum, Quality Assurance Review – Laurence Harbor Petroleum (SDG 120127) Site (August 16, 2007) prepared by NJDEP's Office of Data Quality Hazardous Site Science Element.
- Memorandum, Quality Assurance Review – Laurence Harbor Petroleum (SDG 120128) Site (August 22, 2007) prepared by NJDEP's Office of Data Quality Hazardous Site Science Element.
- Limited Site Investigation Report and Remedial Action Workplan, NJDEP Case No. 07-04-18-1110-28, Laurence Harbor Interceptor Sewer Easement, Block 1 Lot

54.11 & 54.12, Township of Old Bridge, Middlesex County, New Jersey (August 2007) prepared by Icon Engineering.

- Memorandum, Quality Assurance Review – Margaret's Creek Lead Contamination (SDG 121055) Site (September 4, 2007) prepared by NJDEP's Office of Data Quality Hazardous Site Science Element.

- Memorandum, Quality Assurance Review – Margaret's Creek Lead Contamination (SDG 121058) Site (September 4, 2007) prepared by NJDEP's Office of Data Quality Hazardous Site Science Element.

- Permit-by-Rule Application, Discharge to Groundwater Work Plan, NJDEP Case No. 07-04-18-1110-28, Laurence Harbor Interceptor Sewer Easement, Block 1 Lot 54.11 & 54.12, Township of Old Bridge, Middlesex County, New Jersey (September 2007) prepared by Icon Engineering.

- Remedial Action Report, NJDEP Case No. 07-04-18-1110-28, Laurence Harbor Interceptor Sewer Easement, Block 1 Lot 54.11 & 54.12, Township of Old Bridge, Middlesex County, New Jersey (April 2008) prepared by Icon Engineering.

- Summary Letter Report, Raritan Bay Slag, Old Bridge and Sayreville, New Jersey (January 2009) prepared by Weston Solutions, Inc.

- Health Consultation, Evaluation of Environmental Data, Raritan Bay Slag, Old Bridge and Sayreville, Middlesex County, New Jersey, EPA Facility ID: NJN000206276 (February 2009) prepared by U.S. Department of Health and Human Services, Public Health Service, Agency of Toxic Substances and Diseases Registry (ATSDR), Division of Health and Assessment and Consultation.

- Hazardous Ranking System Documentation Record, Raritan Bay Slag (April 2009) prepared by EPA.

- Summary Letter Report Phase II, Raritan Bay Slag, Old Bridge and Sayreville, New Jersey (June 2009) prepared by Weston Solutions, Inc.

- Chemical Assessment Report, Characterization of Slag/Waste Material Fate and Transport of Contaminants Biomonitoring of Contaminants, Report 1 of 2 (June 2009) prepared by Lockheed Martin/REAC.

- Side Scan Sonar and Diver Investigation Surveys at the Raritan Bay Slag Site, Site Investigation and Analytical Results – Work Assignment #0-356 (June 2009) prepared by Lockheed Martin Technology Services/Environmental Services REAC.

- Technical Memorandum, Geophysical Survey, Raritan Bay Slag – Work Assignment # 0-356 (July 2009) prepared by Lockheed Martin.

- Trip Report: Raritan Bay Sediment Sampling, Laurence Harbor, NJ – Work Assignment No. 0-356 (August 2009) prepared by REAC.

- Biological Assessment, Ecological Risk Assessment, Report, 2 of 2, Raritan Bay Slag Site, Old Bridge Township, New Jersey (2010) prepared by Lockheed Martin/REAC.

3.2 NJDEP Preliminary Site Investigation, April 2007 (March 2007 Sampling Results)

3.2.1 Description

NJDEP completed a Preliminary Assessment to review environmental records available for the Margaret's Creek Property (Area 9).

On December 13, 2006, NJDEP completed a limited site investigation to visually characterize fill material using 11 test excavations (test pits). The test pit locations were biased (using historical aerial photographs) to the thickest deposits of fill or based upon evidence of surface waste materials. Test pits were excavated to native material. Minor amounts of non-soil materials were encountered in 1 of the 11 test pits.

On March 4, 2007, representatives of NJDEP's Bureau of Environmental Measurements & Site Assessment collected 17 soil samples. Sample locations were biased toward areas with accumulations of shredded battery casings and areas devoid of vegetation in which refractory brick, slag, and other waste materials were present. Samples L-1 through L-13 were collected in areas of accumulated battery casings and analyzed for lead. Samples S-1 through S-4 were collected in areas devoid of vegetation and were analyzed for Target Analyte List (TAL) metals and the full suite of Target Compound List (TCL) organics. Soil samples analyzed for lead and TAL metals were collected from the 0 to 6-inch interval beneath the waste materials. Soil samples analyzed for TCL organics were collected from 6 to 12 inches bgs.

Figure 6 of the site investigation report, provided in Attachment 1 shows the sample locations where lead was detected and the associated analytical results. Sampling results are included in Appendix B. Only the analytical results for lead were discussed in the report.

3.2.2 Findings

3.2.2.1 Preliminary Assessment

The major findings of the preliminary assessment were as follows:

- The area is not listed in the State's Known Contaminated Sites or Solid Waste Disposal Area databases.

- The owner of the area, Old Bridge Township, did not have knowledge of the nature of the fill material present.

- The area is mapped in NJDEP's GIS as "Critical Emergent Wetland" and as foraging habitat for the State-threatened species the Black-Crowned Night Heron.

- The following observations were made in the report based on review of historic aerial photographs:

  – 1930 – The area observed to be a tidal marsh with a road traversing southwest/northeast of Route 35 to a cluster of structures on Raritan Bay.
  – 1974 – Observed filling of an approximately 20-acre portion of the area.

3.2.2.2 March 2007 Soil Sampling Results

Lead was detected in soil samples collected from locations L-1 through L-13 and S-1 at concentrations above NJDEP's non-restricted future use soil cleanup criterion (400 parts per million [ppm]) and restricted future use soil cleanup criterion (600 ppm), respectively. Lead concentrations ranged from 701 ppm to 146,000 ppm, with an average concentration of 50,482 ppm. Results for analysis of organic compounds were not reported.

The Site Assessment Report recommended that the Green Acres program not purchase the property and that Old Bridge Township be advised of the results of the investigation. The parties were urged to address the contamination under the NJDEP Site Remediation & Waste Management Program.

3.3 NJDEP Sampling Event, May 2007 (May 2007 Sampling Results)

3.3.1 Description

On May 23, 2007, NJDEP conducted an emergency soil sampling event for the Laurence Harbor Seawall Project. A total of 34 surface soil samples and 3 duplicates were collected within Areas 1, 2, 4 and the eastern end of 5. The surface soil samples were collected at various depths and analyzed for TAL metals. Sample locations are presented on Map I of the NJDEP report, which is provided in Attachment 2.

3.3.2 Findings

A complete data set is included in Appendix C; however, only site-specific contaminants (antimony, arsenic, chromium, copper, lead, manganese, nickel, silver, and zinc) are summarized below. Concentrations of these metals frequently exceeded soil screening criteria used in the Weston and EPA Response Engineering and Analytical Contract (REAC) sampling events discussed later in this document.

Analytical results from the NJDEP May 2007 soil investigation indicate concentrations of the following nine metals in soils: Lead (8.1 to 142,000 mg/kg), antimony (0.85 to 12,900 mg/kg), arsenic (2 to 3,350 mg/kg), chromium (6.6 to 54.4 mg/kg), copper (4.2 to 3,590 mg/kg), manganese (17.7 to 542 mg/kg), nickel (0.52 to 286 mg/kg), silver (0.15 to 11.8 mg/kg), and zinc (4.1 to 683 mg/kg).

3.4 NJDEP Sampling Event, July 2007 (July 2007 Sampling

Results)

3.4.1 Description

On July 24, 2007, NJDEP collected surface soil samples at the Old Bridge Waterfront Walkway, in the eastern edge of Areas 1, 2, 4, the eastern end of Area 5 and the western edge of Area 9. Soil samples associated with the NJDEP May 2007 sampling event revealed elevated levels of lead, antimony, and arsenic. The results prompted a second round of surface soil sampling to further investigate the park area where exposure to walkway users was most likely to occur. Thirty-two locations were chosen in the park including an expanse of beach east of the footbridge over Margaret's Creek. All samples were collected from the 0 to 6-inch depth interval and analyzed for TAL metals. Sample locations are presented on Map I of the NJDEP report, which is provided in Attachment 2.

A radiation meter (Micro R/Model 19 with Gamma probe) was used to scan the slag material along the seawall. Gamma readings were within the background range of 5 to 6 microRoentgens per hour. Based on these observations, NJDEP concluded that the slag did not present an immediate radiological concern.

3.4.2 Findings

A complete data set is provided in Appendix D; however, only the contaminants antimony, arsenic, chromium, copper, lead, manganese, nickel, silver, and zinc are summarized below.

Analytical results from the NJDEP July 2007 surface soil investigation detected concentrations of the following nine metals: Lead (3.1 to 545 mg/kg), antimony (0.42 to 20.2 mg/kg), arsenic (1.3 to 24.5 mg/kg), chromium (2.8 to 34.4 mg/kg), copper (1 to 44 mg/kg), manganese (7.2 to 244 mg/kg), nickel (0.52 to 13 mg/kg), silver (0.5 mg/kg), and zinc (4.9 to 51.6 mg/kg).

3.5 OBMUA Limited Site Investigation Report and Remedial Action Work Plan, August 2007 (May 2007 Sampling Results)

3.5.1 Description

In May 2007, sampling was conducted in Area 9. Icon Engineering, on behalf of OBMUA, R3M Engineering Inc., and NJDEP conducted a Limited Site Investigation in the Laurence Harbor Interceptor Sewer construction easement located on Lots 54.11 and 54.12 in Block 1 of the Township of Old Bridge, Middlesex County, New Jersey. The site investigation activities were limited to fill materials located within a 40-foot wide sanitary sewer construction easement that traverses an approximately 60-acre open space parcel (Area 9).

A total of 43 surface (0 to 6 inches) soil samples from the main fill area were screened for metals in the field using a portable X-Ray Fluorescence (XRF) analyzer. Although the XRF results were reviewed, the data are considered to be screening-level and were not used in the data gap evaluation in Section 4. Fifteen samples were analyzed for

TAL metals. Six samples were analyzed for TCL base-neutral SVOCs. A total of six soil samples from the road/beach area were screened with the XRF analyzer; three of these samples were analyzed for TAL metals.

Seven test pits were excavated from depths between 6 and 12 feet bgs to evaluate the fill composition. A total of 23 borings were drilled to depths ranging from 10 to 20 feet bgs to evaluate the fill composition and thickness. Eight samples were collected from the borings and analyzed for full TCL compounds and TAL analytes.

A total of three shallow monitoring wells (MW1, MW2, and MW3) were installed by ICON Engineering in July 2004 to evaluate groundwater levels for dewatering operations performed in connection with installation of the pipeline. The wells were installed in the silty marsh deposits where the pipeline was expected to be installed. The three wells were constructed of polyvinyl chloride (PVC) and fitted with 10-foot PVC screens. Two of the wells were drilled to 15 feet (MW2 and MW-3) and one was drilled to 20 feet (MW-1). These wells were redeveloped, sampled, and the samples were analyzed for TCL VOCs (TCL VO+10) and TAL metals.

Sample locations and contaminant detections are presented in Attachment 3, including Figures 4-A, 4-B, 6 and 7 from the OBMUA Report. Results are included in Appendix E.

Based on the results, a Remedial Action Work Plan (RAWP) proposed excavation and off-site disposal of the contaminated soil and post-excavation XRF sampling with laboratory confirmation. The proposed remedial action was limited to contaminated fill soil within the 40-foot wide construction easement. The findings of the investigation and main features of the proposed remedial action are described in the following two sections.

3.5.2 Findings

- No correlation was observed between the groundwater quality and the soil contamination; lead was below the Class IIA groundwater quality standard in the groundwater samples.

- The thickness of the fill layer within the area of investigation varied from about 7.5 to 15 feet bgs.

- Contaminated soil was only present in a limited section of the construction easement and appeared to be surficial. Contaminants of concerns were identified to be lead, antimony, arsenic, and chromium.

- The following contaminants were detected in soil samples collected from the fill area soils: Lead (non-detect to 24,000 mg/kg), antimony (non-detect to 110 mg/kg), arsenic (non-detect to 23 mg/kg), and chromium (non-detect to 45 mg/kg).

- The following contaminants were detected in the Road/Beach areas soils: Lead (7.1 to 370 mg/kg), antimony (non-detect to 6.6 mg/kg), arsenic (non-detect to 16 mg/kg), and chromium (non-detect to 17 mg/kg).

- XRF soil screening results exceeded soil screening concentrations for five metals: Antimony (85 to 210 ppm), arsenic (22 to 852 ppm), cadmium (41 to 45 ppm), mercury (17 to 156 ppm), and lead (667 to 39,162 ppm).

- Groundwater screening samples exceeded screening concentrations for nine metals: Aluminum (11,000 µg/L), antimony (7.5 µg/L), arsenic (4 to 5.1 µg/L), beryllium (1.1 to 4 µg/L), iron (8,100 to 110,000 µg/L), manganese (160 to 690 µg/L), and sodium (250,000 µg/L).

3.5.3 Remedial Action Selection

The RAWP concluded that contaminated fill material was present in limited portions of the sewer construction easement. Due to the apparent limited extent of contamination within the easement, excavation and off-site disposal of the contaminated fill was the recommended remedial approach. Remediation of the contaminated fill material within the construction easement would be coordinated with the sewer construction activities and would take place prior to construction. The RAWP did not address contamination outside of the construction easement.

3.6 OBMUA Remedial Action Report, April 2008 (October 2007 to February 2008 Sampling Results)

3.6.1 Description

Between November 2007 and February 2008, Icon Engineering on behalf of OBMUA, R3M Engineering Inc. and NJDEP conducted remedial action activities within a portion of a 40-foot wide sanitary sewer construction easement. This area is the upland road area that traverses the Margaret's Creek wetland in Area 9. The objective of the remediation was to remove the contaminated fill materials from the construction easement so that the proposed sewer line could be installed in Area 9.

On October 25, 2007, prior to the remedial action, six pre-remedial samples were collected and analyzed for total lead and for toxicity characteristic leaching procedure (TCLP) lead to classify the waste for disposal.

Contaminated soil was removed with an excavator and stockpiled pending off-site disposal. Soil excavation ranged from 6 to 18 inches below the pre-existing grade. All of the excavated soil was classified as hazardous due to lead TCLP concentrations. A total of 1,075 tons of hazardous soil was excavated and disposed of offsite.

Thirty-five final post-excavation samples were collected to document the effectiveness of the remedial action. Final post-excavation samples were analyzed with XRF equipment. Seven confirmatory samples were collected and shipped to a state-certified laboratory for antimony, arsenic, hexavalent chromium, and lead analyses. Sample

locations and detection figures are presented in Figures 2 and 3 of the OBMUA Report provided in Attachment 4. Results are included in Appendix F.

3.6.2 Findings

- The pre-remedial soil samples had lead concentrations up to 152 milligrams per liter (mg/L) in the TCLP leachate, indicating that the excavated soil would be considered hazardous waste.

- Results for the post-excavation soil samples indicated concentrations of the following three metals: Lead (17 to 400 mg/kg), antimony (non-detect to 4.7 mg/kg), and arsenic (3 to 17 mg/kg). Hexavalent chromium was analyzed but not detected in post-excavation soil samples.

- XRF soil screening results indicated concentrations of the following four metals: Antimony below the limit of detection (LOD), arsenic (7 to 17 mg/kg), chromium below the LOD, and lead (12 to 297 mg/kg). Antimony and chromium had high levels of uncertainty with maximum values of ± 185 and 167, respectively.

3.7 EPA Summary Letter Report, Phase I Investigation, January 2009 (September 2008 Sampling Results)

3.7.1 Description

From September 10 through 16, 2008, EPA's contractor, Weston Solutions, Inc, conducted an Integrated Assessment (IA) sampling program. During the IA, Weston collected a total of 48 aqueous samples, 95 surface soil samples, 10 subsurface soil samples, and 84 sediment samples. Sample locations, sample identification, and analytical results for the IA are presented in Figures 1 through 6 of the Phase I report and are provided in Attachment 5. Results are included in Appendix G.

Surface water samples were collected from Area 1, Area 2, Area 4, and Areas 6 through 9. The surface water samples collected from Area 6 were localized within the beach area parallel to the inlet along the eastern side of the Cheesequake Creek Inlet. Surface water samples were analyzed for TAL total metals and dissolved metals (excluding mercury and including tin) through the EPA CLP.

The sediment samples were collected from 0 to 3 inches below the sediment surface from Area 1, Area 2, Area 6, Area 8, Area 9, and the background location (Area 10). Sediment samples collected from Area 1 were localized in the area west of Margaret's Creek. Additional sediment samples were collected from a localized area west of the Cheesquake Creek Inlet western jetty, within Area 8. Sediment samples were analyzed for TAL metals through EPA's CLP and for grain-size distribution.

The surface soil samples were collected from 0 to 2 inches bgs from Areas 1 through 3, Areas 5 through 8, and background locations (Area 10). Surface soil samples were also collected from localized areas within Areas 1 and 6 described above. Surface soil samples collected from Area 5 were concentrated on the eastern portion of the beach. Subsurface soil samples (6 to 12 inches, 12 to 18 inches) were collected from Area 1, Area 2, Area 5, and Area 8. Additional surface and subsurface soil samples were

collected from a localized area west of the western inlet jetty, within Area 8. Surface and subsurface soil samples were analyzed for TAL metals and TCLP metals through the EPA CLP.

3.7.2 Findings

Analytical results for samples collected during the IA investigation are summarized by area in the sections below.

3.7.2.1 Area 1: Laurence Harbor Seawall

- Surface soil samples had lead ranging from 44.8 to 16,000 mg/kg. The maximum concentration of copper is 74.4 mg/kg. Antimony and arsenic data were rejected as unusable during the data validation process.

- Subsurface soil samples had lead ranging from 22.5 to 1,100 mg/kg. The maximum concentration of copper is 51.4 mg/kg. Antimony and arsenic data were rejected as unusable during the data validation process. Four soil samples analyzed for TCLP metals exceeded the 0.5 mg/L RCRA limit for lead.

- Analytical results for surface water samples showed a maximum lead concentration of 153 µg/L.

- Surface soil samples within the localized area west of Margaret's Creek had lead ranging from 11.4 to 10,200 mg/kg. Maximum concentrations for the three following metals were: Antimony (120 mg/kg), arsenic (48.3 mg/kg), and copper (186 mg/kg).

- Sediment samples collected within the localized area west of Margaret's Creek had lead ranging from 7.3 to 5,860 mg/kg. Maximum concentrations for the three following metals were: Antimony (33.2 mg/kg), arsenic (22.5 mg/kg), and copper (117 mg/kg).

- Based on grain size distribution analysis, sediment samples within Area 1 contained 96.7% sand and gravel.

3.7.2.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty)

- Surface soil samples had lead ranging from 57.9 mg/kg to 1,630 mg/kg.

- Subsurface soil samples (6 to 12 inches, 12 to 18 inches) had lead ranging from 649 to 23,800 mg/kg. Maximum concentrations detected for the three following metals were: Antimony (832 mg/kg), arsenic (602 mg/kg), and copper (704 mg/kg).

- Sediment samples had lead ranging from 200 to 533 mg/kg. Maximum concentrations detected for the three following metals were: Antimony (32.9 mg/kg), arsenic (55.7mg/kg), and copper (46.7 mg/kg).

- Surface water samples collected from the beach area had an average lead concentration of 1,179 µg/L, with a maximum lead concentration of 1,450 µg/L. Maximum concentrations of the three following metals were: Antimony (29 µg/L), arsenic (34.5 µg/L), and copper (67.7 µg/L).

- Based on grain size distribution analysis, sediment samples within Area 2 contained 96.7% sand and gravel.

3.7.2.3 Area 3: Laurence Harbor Playground

Soil samples collected from the playground area had lead ranging from 8.9 to 97.8 mg/kg. Maximum concentrations for the three following metals were: Antimony (0.42 mg/kg), arsenic (144 mg/kg), and copper (131 mg/kg).

3.7.2.4 Area 4: Old Bridge Waterfront Park (Walking Park Parallel to Seawall)

The surface water sample collected from the backside of the seawall in the wetland near Margaret's Creek had a maximum lead concentration of 298 µg/L.

3.7.2.5 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty)

Surface soil samples had lead ranging from 109 to 935 mg/kg. The maximum concentration of copper was 75.7 mg/kg. Antimony and arsenic data were rejected as unusable during the data validation process.

3.7.2.6 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty)

- Surface soil samples had lead ranging from 1.7 to 94.1 mg/kg. The maximum concentrations for the following two metals were: Arsenic (9.2 mg/kg) and copper (15 mg/kg).

- Sediment samples had lead ranging from 1.2 to 11.4 mg/kg. Maximum concentrations of the three following metals were: Antimony (0.86 mg/kg), arsenic (3.7 mg/kg), and copper (11.0 mg/kg).

- Surface water samples had maximum concentrations of three metals: Lead (99 µg/L), arsenic (15.2 µg/L); and copper (23.9 µg/L).

- Based on grain size distribution analysis, sediment samples within Area 6 contained 96.7% sand and gravel.

3.7.2.7 Area 7: Cheesequake Creek Inlet

- Surface soil samples collected from the localized area within the beach area parallel to the inlet, along the eastern side of the Cheesequake Creek Inlet had lead ranging from 1.8 to 4.4 mg/kg. Arsenic and copper data were rejected as unusable during the data validation process.

- Surface water samples from Area 7 had maximum concentrations of two metals: Lead (6.7 µg/L) and arsenic (4.8 µg/L).

- Sediment samples had maximum concentrations of the three following metals: antimony (3,270 mg/kg), arsenic (2,100 mg/kg), and copper (2,050 mg/kg). Note that data for lead were rejected as unusable during the data validation process due to quality control issues.

- Based on grain size distribution analysis, sediment samples within Area 7 contained 96.7% sand and gravel.

3.7.2.8 Area 8: Cheesequake Creek Inlet Western Jetty

- Surface soil samples had lead ranging from 54,800 mg/kg to 198,000 mg/kg. Maximum concentrations of the four following metals were: Antimony (3,120 mg/kg), arsenic (2,470 mg/kg), and copper (4,630 mg/kg).

- Maximum concentrations of lead (731 mg/kg), arsenic (15.4 mg/kg), and copper (76.6 mg/kg) were detected in subsurface soil samples. TCLP lead concentrations exceeded the RCRA limit by a magnitude of 100 to 250 times.

- Sediment samples had lead ranging from 29.6 to 2,150 mg/kg. Maximum concentrations of the three following metals were: Antimony (53.7 mg/kg), arsenic (62.9 mg/kg), and copper (204 mg/kg).

- Maximum concentrations of lead (1,810 µg/L), antimony (53.2 µg/L), arsenic (70.9 µg/L), and copper (154 µg/L) were detected in surface water samples.

- One subsurface soil sample was collected from the area west of the western inlet jetty and had the four following metals: Lead (21,500 mg/kg), antimony (419 mg/kg), arsenic (228 mg/kg), and copper (489 mg/kg).

- Surface soil samples collected from the area west of the western inlet jetty had lead ranging from 231 to 14,200 mg/kg. Maximum concentrations of the three following metals were: Antimony (616 mg/kg), arsenic (198 mg/kg), and copper (340 mg/kg).

- Based on grain size distribution analysis, sediment samples within Area 8 contained 72% sand and gravel.

3.7.2.9 Area 9: Margaret's Creek

- Sediment samples had lead ranging from 23.8 mg/kg to 279 mg/kg. The maximum concentrations for the three following metals were: Antimony (2.1 mg/kg), arsenic (16.1 mg/kg), and copper (62.7 mg/kg).

- Maximum concentrations of lead (49.9 µg/L), antimony (2.5 µg/L), arsenic (21. 6 µg/L); and copper (15.2 µg/L) were detected in surface water samples collected from Area 9.

- Based on grain size distribution analysis, sediment samples within Area 9 contained 72% sand and gravel.

3.7.2.10 Background

Based on grain size distribution analysis, sediment samples within the background area contained 96.7% of sand and gravel. The background sampling area is located east of Area 9, on the shore of Raritan Bay (Figure 1-1) and has been designated as Site Area 10.

- Sediment samples collected from a background area detected maximum concentrations for the three following metals: Antimony (1.1 mg/kg), arsenic (10.6 mg/kg), and copper (4.9 mg/kg). Lead data were rejected as unusable during the data validation process due to quality control issues.

3.8 EPA Hazard Ranking System Documentation Record, Raritan Slag, April 2009

3.8.1 Description

EPA's Hazard Ranking System (HRS) is one of the mechanisms that EPA uses to evaluate sites for potential inclusion on the National Priorities List (NPL). The HRS evaluates three migration pathways (soil, groundwater, and air) and one exposure pathway (soil). For each pathway, three major factor categories are evaluated, the likelihood of a release of a hazardous substance, pollutant, or contaminant; waste characteristics (e.g., waste quantity, containment, toxicity); and targets (potential for exposure of human and ecological receptors). The HRS used data and observations obtained from the NJDEP 2007 site investigations and the EPA 2008 investigation. The NJDEP 2007 data is summarized in Sections 3.3 and 3.4 of this Technical Memorandum. The EPA 2008 investigation is summarized in Section 3.7 of this Technical Memorandum.

3.8.2 Findings

Only one migration pathway, surface water, was scored. The groundwater migration, soil exposure, and air migration pathways of the HRS were not scored.

Two waste source areas using the HRS term slag piles located within one watershed (i.e., Raritan Bay) were evaluated in the HRS. Both are slag piles located along the southern shoreline of Raritan Bay (Figures 1 and 2 of the HRS Document in Attachment 6). Figure 3 of the HRS document, provided in Attachment 6, illustrates the 15-mile surface water migration pathway. The waste sources evaluated in the HRS included:

- Source 1 – Slag Waste Pile - Lawrence Harbor Seawall Slag Waste Pile (Area 1)

- Source 2 – Slag Waste Pile - Western Jetty of Cheesequake Inlet (Area 8)

Source areas are shown on HRS Figure 3. The major findings of the HRS for the Raritan Bay Slag Site are summarized below.

Likelihood of Release - Based on analytical data from the EPA sampling investigation conducted in September 2008, the HRS documented that lead is being released from both waste sources and impacting the Raritan Bay watershed. Releases were documented by direct observation, through direct contact of Raritan Bay waters with the waste, and by analytical data for lead-contaminated sediment samples collected from Raritan Bay. Contaminant concentrations in sediment were evaluated against contaminant concentrations in background samples.

Waste Characteristics – The HRS documented the quantity and the toxicity, persistence, and bioaccumulation factors for the two waste sources that were evaluated; lead was the primary waste constituent.

The waste characteristics evaluation cited TCLP data for lead to support documentation of waste characteristics factors.

Targets – A number of potential targets or receptors, both human and ecological, were identified and evaluated in the HRS surface water pathway. These included the potential for impacts on the human food chain (e.g., via consumption of fish), impacts to resources (parks and other resources), and sensitive environments such as wetlands and endangered species. The following major targets were evaluated in the surface water pathway:

- Human Food Chain - Raritan Bay fisheries (potential for exposure via consumption of fish from Raritan Bay).

- Resources - Old Bridge Waterfront Park was evaluated as a resource.

- Sensitive Environments – NY-NJ Harbor estuary which is identified as a sensitive area under the National Estuary Program, and Raritan Bay, a state-designated area for protection of aquatic life.

Evaluation of the surface water migration pathway resulted in the maximum score for the pathway (100) and an overall site score of 50, which is above the minimum score required to consider the area for NPL inclusion. The Raritan Bay Slag Site was listed on the NPL on November 2, 2009.

3.9 EPA Summary Letter Report, Phase II Investigation, June 2009 (April 2009 Sampling Results)

3.9.1 Description

From April 20 through 23, 2009, Weston Solutions, Inc. conducted a Phase II Sampling Program that included collection of 384 environmental samples (including duplicate samples). Weston collected 134 surface and near-surface soil samples, 116 sediment

samples, and 34 surface water samples from the site. Surface soil and sediment samples were collected from 0 to 2 inches and 0 to 3 inches, respectively. Soil samples were collected at various depths including 0 to 2 inches, 6 to 12 inches, 12 to 18 inches, and 18 to 24 inches bgs. Sample locations, sample identification, and analytical results for the Phase II investigation are presented in Figures 1 through 6 of the Phase II Report, provided in Attachment 7. Surface water, sediment, and surface soil samples were collected from Area 5, Area 6, and Area 9. Sediment samples were also collected from a background area (Area 10). Near-surface soil samples were collected from Area 5 and Area 6. All samples were analyzed for TAL metals (excluding mercury). Surface water samples were also analyzed for dissolved metals. The results are included in Appendix I.

3.9.2 Findings

Samples were not collected from Area 1 through Area 4, Area 7, and Area 8 during the June 2009 Phase II sampling event, so these Areas are not discussed Results of the Phase II Investigation for Area 5, Area 6, Area 9, and the background location (Area 10) are summarized below.

3.9.2.1 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty)

- Key metals detected in surface soil samples include: Lead (1.7 to 771 mg/kg), arsenic (1.5 to 43.8 mg/kg), antimony (non-detect to 53.9 mg/kg), and copper (1 mg/kg to 58.9 mg/kg).

- Key metals detected in the near-surface soil samples include: Lead (5.1 to 364 mg/kg), antimony (non-detect to 15.7 mg/kg), arsenic (4.7 to 13.9 mg/kg), and copper (2.5 to 18.7 mg/kg).

- Key metals detected in sediment samples include: Lead (14.4 to 1,090 mg/kg), antimony (non-detect to 47.1 mg/kg), arsenic (2.2to 38 mg/kg), and copper (2.8 to 49.3 mg/kg).

- Key metals detected in surface water samples include: Lead (67.9 to 767 µg/L), antimony (3.5 to 26.2 µg/L), arsenic (5.9 to 27.9 µg/L), and copper (8 to 49.4 µg/L). Dissolved metals detected in surface water samples included lead (3.8 µg/L), antimony (3.9 µg/L), and copper (1.2 to 6.3 µg/L).

3.9.2.2 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty)

- Key metals detected in surface soil samples include: Lead (2.1 to 18.5 mg/kg), arsenic (2 to 4.7 mg/kg), and copper (0.86 to 37.2 mg/kg).

- Key metals detected in near-surface soil samples include: Lead (2.1 to 25.5 mg/kg), antimony (non-detect to 0.96 mg/kg), arsenic (1.4 to 12.1 mg/kg), and copper (1.1 to 7.1 mg/kg).

- Key metals detected in sediment samples include: Lead (1.1 to 34.6 mg/kg), antimony (non-detect to 7 mg/kg), arsenic (1.3 to 15.4 mg/kg), and copper (1.3 to 31.3 mg/kg).

- Key metals detected in surface water samples include: Total lead (10.2 to 209 µg/L), total arsenic (non-detect to 13.1 µg/L), and total copper (1.4 to 2.1 µg/L).

3.9.2.3 Area 9: Margaret's Creek

- Key metals detected in surface soil samples include: Lead (1.7 to 28.9 mg/kg), arsenic (0.69 to 11.4 mg/kg), and copper (0.46 to 35.8 mg/kg).

- Key metals detected in sediment samples include: Lead (3 to 21.6 mg/kg), arsenic (0.95 to 19.1 mg/kg), and copper (1.1 to 27.1 mg/kg).
- Key metals detected in surface water samples include: Total lead (5.8 to 37 µg/L), total arsenic (1.9 to 7 µg/L), and total copper (4.8 to 11.6 µg/L). Dissolved concentrations of arsenic (non-detect to 5.4 µg/L) and copper at (non-detect to 2 µg/L) were detected.

3.9.2.4 Background

Key metals detected in background sediment samples include: Lead (2.4 to 7.1 mg/kg), arsenic (maximum at 4.2 mg/kg), and copper (maximum at 5.2 mg/kg).

3.10 EPA Chemical Assessment Report, Raritan Bay Slag Site, June 2009 (September 2008 Sampling Results)

3.10.1 Description

From September 10 to 22, 2008, Lockheed Martin/REAC personnel conducted a chemical assessment investigation. During the investigation, samples of slag, beach sediment, pore water, ribbed mussels, long neck clams, hard shell clams, killifish, and sea lettuce were collected. The field investigation and the chemical assessment report covered two Site Areas: Area 1, the Lawrence Harbor Seawall and Area 8, the Cheesequake Creek Inlet Western Jetty as these are the two known slag source areas. Sample locations and identifications are presented in Figures 2 and 3 of the Chemical Assessment Report, provided in Attachment 8. Sampling locations within the slag did not have GPS coordinates; therefore, figures do not exist for those locations. The field investigation activities and sample analyses performed as part of the chemical assessment investigation are summarized below. Results are provided in Appendix H.

- Slag Sampling and Analysis - A total of 17 slag samples were collected from Area 1 and Area 8. Slag samples were analyzed for elemental metal composition for the primary metals of interest (arsenic, copper, lead, antimony, tin, and zinc) and for the dominant mineral or chemical species using X-Ray Diffraction (XRD). In addition, two leachability tests were performed. The TCLP test was performed to evaluate the leachability of metals from the slag under acidic conditions. The

second test evaluated the leachability of metals from the slag using a neutral salt solution.

- Biota Sampling and Analysis – The biota sampling activities are described below. Biota samples, including killifish, ribbed mussels, long neck clams, hard shell clams, and sea lettuce, were shipped to the subcontract laboratory, homogenized, and analyzed for TAL metals, tin, and percent solids.

  - Killifish - Five composite killifish samples were collected from areas along the Area 1 seawall using a seine net. Each of the five composite samples consisted of eight individual killifish.

  - Ribbed Mussels – Ribbed mussels (*Gukensia demissa*) were collected during mid-tide from six sample location areas along the Area 1 seawall. Each of the six samples consisted of approximately 8 to 12 ribbed mussels. Ribbed mussels were prevalent among the *Spartina* sp. (marsh grass) beds located approximately 40 to 60 feet from the seawall.

  - Long Neck Clams – Long neck clams (*Mya arenaria*) samples were collected during mid-tide from five locations along the Area 1 seawall or near the *Spartina* sp. beds. From 5 to 106 clams were collected from each of the five sampling areas.

  - Hard Shell Clams - A total of 10 hard shell clams (*Mercenaria mercenaria*) were collected during mid-tide, just offshore of the Area 1 seawall, using a clam rake in waters 3.5 to 4 feet deep. Hard shell clams were subdivided into three composite samples based on three size ranges (small, medium, and large).

  - Sea Lettuce – Five composite samples of sea lettuce (*Ulva* sp.) were collected from the substrate (large stone and rocks), just beyond the *Spartina* sp. beds, during mid-tide.

- Soil (beach sediment) Sampling and Analysis - Eleven co-located soil (i.e., beach sediment) samples were collected from ribbed mussel and long neck clam sample locations in Area 1. Soil samples were analyzed for TAL metals and tin by a subcontract laboratory.

- Pore Water Sampling and Analysis – Five pore water samples were collected from Area 1. Pore water samples were collected within each of the five long neck clam sampling areas and analyzed for TAL metals and tin as total metals, and for dissolved metals (filtered) by a subcontract laboratory.

Lockheed Martin/REAC attempted to collect polycheate worms using a clam rake. Sampling attempts were made during low-to mid-tide levels. However, the mass of polycheate worms collected was insufficient to meet data quality objectives and the sampling task was abandoned.

3.10.2. Findings – Chemical Assessment Report, June 2009

3.10.2.1 Area 1: Laurence Harbor Seawall

Results of the chemical assessment investigation are summarized below.

Slag Characterization Results - Sampling results for slag derived from Area 1 are summarized in this section. The relevant results include elemental analysis of the slag and the two leachability testing procedures: TCLP and the neutral salt leaching test.

- Lead Speciation - Five different lead species were identified as dominant species in the slag. For two of three samples, lead carbonate ($PbCO_3$) was identified as the dominant lead species in the interior of the slag. For the exterior of the slag, elemental lead (Pb^0) and lead zinc oxide ($PbZnO_3$) were the dominant lead species. These results are consistent with a conclusion that the slag is weathering, which would release contamination from the source material.

- Elemental Analysis - Analysis of the slag associated with Area 1 indicated the following concentrations of six metals (some in the percent range): Lead (675 to 79,900 mg/kg), arsenic (21 to 9,900 mg/kg), antimony (36 to 71,300 mg/kg), copper (3,370 to 445,000 mg/kg), tin (25 to 9,030 mg/kg), and zinc (49 to 13,500 mg/kg). The wide range of metals concentrations suggests that the slag is highly heterogeneous.

- TCLP Leachability - The TCLP protocol provides an assessment of metals potentially being released under exposure to acidic groundwater and/or rainwater conditions, and evaluates the acceptability of the slag for landfill disposal. All 17 slag samples exceeded the 5.0 mg/L RCRA regulatory limit for lead; leachable lead levels ranged from 17 mg/L to 3,140 mg/L. Lead leached from the interior of the samples versus the exterior of samples was variable. Comparison of lead concentrations in three interior/exterior sample pairs indicate that lead concentrations were greater in the interior sample for one sample pair, greater in the exterior sample of a second sample pair, and approximately equal in the third sample pair. The results of the TCLP procedures demonstrate that the slag material fails TCLP and is, therefore, a hazardous waste.

- Neutral Salt Leachability - Lead was determined to be leachable from the neutral salt solution exposures. Higher levels of lead were leached from the interior samples compared with the exterior of the slag. The exterior samples had leachable lead ranging from 8.3 to 10.1 mg/kg, compared to the interior samples with leachable lead ranging from 70.9 to 870 mg/kg. The results of the neutral salt extraction tests demonstrated that contaminants can be released from the slag under existing environmental conditions.

Analytical results for soil, pore water, killifish, ribbed mussel, long neck clam, hard shell clam, and sea lettuce samples are summarized below.

- Soil Samples - Analytical results for key metals detected in soil samples are as follows: Lead (12 to 660 mg/kg), antimony (0.22 to 6.1 mg/kg), arsenic (5.4 to 29 mg/kg), copper (4.4 to 31 mg/kg), and chromium (7.7 to 46 mg/kg).

- Pore Water Samples – Analytical results for total metals (unfiltered) and dissolved metals (filtered) are as follows: Total lead (8 to 2,400 µg/L), dissolved lead (2 to 170 µg/L), total antimony (2 to 270 µg/L), dissolved antimony (2 to 130 µg/L), total arsenic (19 to 230 µg/L), dissolved arsenic (11 to 86 µg/L), total copper (40 to 91 µg/L), dissolved copper (20 to 40 µg/L), total chromium (7.6 to 17 µg/L), and dissolved chromium (6 to 7.1 µg/L).

- Killifish Samples - Analytical results for key metals detected in killifish samples are as follows: Lead (0.49 to 0.92 mg/kg), antimony (0.16 to 0.29 mg/kg), arsenic (3.5 to 3.8 mg/kg), copper (4.8 to 6.1 mg/kg), and chromium (0.98 to 1.3 mg/kg).

- Ribbed Mussel Samples - Analytical results for key metals detected in ribbed mussel samples are as follows: Lead (3 to 8.6 mg/kg), antimony (0.19 to 0.25 mg/kg), arsenic (6.1 to 9.5 mg/kg), copper (10.4 to 16 mg/kg), and chromium (1.3 to 2.3 mg/kg).

- Long Neck Clam Samples - Analytical results for key metals detected in long neck clam samples are as follows: Lead (3.4 to 17 mg/kg), antimony (0.15 to 1.2 mg/kg), arsenic (1.4 to 7.6 mg/kg), copper (8.5 to 31 mg/kg), and chromium (0.67 to 3.1 mg/kg).

- Hard Shell Clam Samples - Analytical results for key metals detected in long neck clam samples are as follows: Lead (1.7 to 3.1 mg/kg), antimony (0.1 to 0.11 mg/kg), arsenic (5.1 to 9.8 mg/kg), copper (11 to 14.3 mg/kg), and chromium (1.2 to 1.8 mg/kg).

- Sea Lettuce Samples - Analytical results for key metals detected in sea lettuce samples are as follows: Lead (24 to 80 mg/kg), antimony (0.23 to 0.75 mg/kg), arsenic (4.7 to 15 mg/kg), copper (9.7 to 13 mg/kg), and chromium (2.6 to 5 mg/kg).

3.10.2.2 Area 8: Cheesequake Creek Inlet Western Jetty

Results of the slag characterization for Area 8 are summarized below.

- Elemental Analysis - Analysis of the slag associated with Area 8 indicated the following concentrations of six metals (some in the percent range): Lead (889 to 131,000 mg/kg), arsenic (8 to 15,200 mg/kg), antimony (31to 46,800 mg/kg), copper (101 to 11,600 mg/kg), tin (31 to 11,400 mg/kg), and zinc (385 to 9,790 mg/kg).

- Lead Speciation – The dominant lead species identified in slag samples determined by XRD include elemental lead (Pb^0), lead carbonate (cerussite [$PbCO_3$]), lead zirconium oxide, lead sulfate (anglesite [$PbSO_4$]), and lead oxide (litharge [PbO]). Arsenic, copper, and antimony species were also present in the slag. Lead carbonate is soluble under environmental conditions and could leach from the slag.

- TCLP Leachability -Analytical results from TCLP assay based on metals leached (as mg/L) from slag samples detected concentrations of the following metals: Lead (23 to 3,140 mg/L), arsenic (<0.02 to 0.18 mg/L), antimony (<0.02 to 10.1 mg/L), copper (<0.02 to 0.25 mg/L), and zinc (0.24 to 19 mg/L). Based on a 5.0 mg/L RCRA regulatory limit for lead and the leachable concentrations of lead (23 to 3,140 mg/L), the slag would be considered hazardous waste under RCRA.

- Neutral Salt Leachability - Analytical results of the neutral salt assay based on metals leached (as mg/kg dry weight) from slag samples indicate concentrations of four metals: Lead (0.2 to 870 mg/kg), arsenic (<0.1 to 1 mg/kg), antimony (<0.1 mg/kg to 1 mg/kg), and zinc (<0.1 to 126 mg/kg). These results indicate that lead can be leached from slag under environmental conditions.

3.11 EPA Trip Report: Raritan Bay Sediment Sampling, August 2009 (June to July 2009 Sampling Results)

3.11.1 Description

Offshore and onshore sediment core sampling was conducted by EPA REAC in June and July 2009 to evaluate the extent of contamination in offshore sediments in Raritan Bay adjacent to the Cheesequake Creek Inlet jetties, the seawall, and the coastal subtidal zone. A core sampler was used to collect sediment at depths from 0 to 6 inches, 0 to 12 inches, and 12 to 24 inches. Each core sample was homogenized prior to sediment collection. A total of 354 sediment samples were collected from Areas 1, 2, and 5 through 8. All of the sediment samples were sent to a CLP laboratory for metals analysis. An additional 34 samples collected from 0 to 6 inches were also analyzed for VOCs, (SVOCs, pesticides, and PCBs. The same 34 sample locations were also analyzed for total organic carbon (TOC) from 0 to 6 inches and 12 to 24 inches.

3.11.2 Findings

Lead was the only contaminant assessed and presented on figures in the EPA Core Sampling Trip Report dated August 2009. Lead concentrations were color coded by ranges to show exceedences relevant to other samples in the same media. Sample locations and results are provided in Figures 1 through 3 of the EPA report, included in Attachment 9. Results are included in Appendix J. The results are compared against the NJDEP Effects Range-Low level for lead (47 mg/kg) in sediments.

3.11.2.1 Area 1: Laurence Harbor Seawall

- Sediment samples collected from 0 to 6 and 0 to 12 inches had lead ranging from 47 to greater than 400 mg/kg. Lead exceeding 47 mg/kg mainly bordered Margaret's Creek (Area 9) and the first jetty, as well as along the seawall.

- Sediment samples collected from 12 to 24 inches had lead below 47 mg/kg, with one sample above 400 mg/kg along the seawall.

3.11.2.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty)

- Sediment samples collected from 0 to 6 inches had lead concentrations ranging from 47 mg/kg to greater than 400 mg/kg. All but two samples, collected further into the bay, had lead concentrations greater than 100 mg/kg. Sediment samples that exceeded 400 mg/kg were concentrated along the shoreline.

- Sediment samples collected from 0 to 12 and 12 to 24 inches had lead ranging from less than 47 to greater than 400 mg/kg. Lead exceeding 47 mg/kg was mainly concentrated along the shoreline.

3.11.2.3 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty)

- Sediment samples collected from 0 to 6 and 0 to 12 inches had lead ranging from less than 47 to 400 mg/kg. Sediment samples that exceeded 47 mg/kg were concentrated between the first and second jetties. Four samples had lead above 47 mg/kg between the second and third jetty.

- Sediment samples collected from 12 to 24 inches had lead below 47 mg/kg. One sample, located along the first jetty, had lead between 101 and 400 mg/kg.

3.11.2.4 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty)

- Sediment samples collected from 0 to 6, 0 to 12, and 12 to 24 inches had lead below 47 mg/kg. One sample from each sampling depth, each at different locations, had lead between 47 and 100 mg/kg.

3.11.2.5 Area 7: Cheesequake Creek Inlet

- Sediment samples from Area 7 were collected further into the bay and not between the Cheesequake Inlet's jetties.

- Sediment samples collected from 0 to 6 inches had lead ranging from greater than 47 to less than 400 mg/kg. Sediment samples collected from 0 to 12 inches had lead ranging from greater than 47 to 400 mg/kg

- Sediment samples collected from 12 to 24 inches had lead below 47 mg/kg. Only one sample had lead above 400 mg/kg.

3.11.2.6 Area 8: Cheesequake Creek Inlet Western Jetty

- Sediment samples collected from 0 to 6, 0 to 12, and 0 to 24 inches had lead ranging from less than 47 to greater than 400 mg/kg. Sediment samples that had lead above 47mg/kg were mainly concentrated along the shoreline and Cheesequake Inlet's western jetty.

3.12 Additional Information

3.12.1 EPA Aerial Photography 1957 to 2008

Aerial photographs were obtained from EPA Region 2. The aerial photographs were taken in 1957, 1963, 1966, 1967, 1969, 1970, 1972, 1973, 1974, 1977, 1978, and 2008. The aerial photographs adequately cover the period of interest. The photographs were reviewed by CDM and the following observations were made.

3.12.1.1 Cheesequake Creek and West Jetty Inlet Aerials

- From 1957 to 1963 – Development is evident on the beach area west of the western jetty. Buildings removed from the beach area east of the eastern jetty. Both the eastern and western jetties are more pronounced.

- 1977 – A white mass is present along the shore of the western jetty inlet.
- 1978 – The white mass is no longer present along the shore of the western jetty inlet.

- 2008 – Buildings were removed from the western jetty inlet.

3.12.1.2 Laurence Harbor Seawall and Margaret's Creek (previously called Marquis Creek)

- From 1957 to 1963 – A housing development is present east of the creek. Buildings were removed from the beach area along the seawall.

- 1967 – Three buildings were constructed southeast of the creek, along the southern side of Route 35.

- 1972 – Circular objects are present within the creek, south of the creek's mouth. The circular objects are aligned along the eastern edge of the creek.

3.12.2 Regional Environmental Monitoring and Assessment Program, 2003

The 2003 REMAP report was reviewed. The stated purpose of the REMAP sampling is to assess contaminant trends in and the biological health of Raritan Bay. The REMAP data may be useful for establishing regional background concentrations for Raritan Bay. The REMAP data is discussed further in Section 4.2.5. A total of 28 sediment samples were collected and analyzed for TAL metals. Attachment 10 provides a figure showing the sampling locations. Results are included in Appendix K. Information relevant to use of the REMAP data to define background concentrations for metals in Raritan Bay is summarized below.

- The highest concentrations of lead were present at eight sampling locations: RB303, RB304, RB308, RB310, RB316, RB353, RB354, and RB363.

- Mercury was present at the sample locations that observed the highest lead detections. Sample location RB301, however, had the highest concentration at approximately 5.5 times the mean concentration.

- Analytical results from the REMAP detected TOC ranging from 2,100 mg/kg to 76,000 mg/kg.

- Analytical results from the REMAP detected 15 metals. Results for key metals were as follows: Antimony (0.18 to 2.3 mg/kg), arsenic (0.94 to 22.6 mg/kg), cadmium (0.19 to 2.7 mg/kg), chromium (5.1 to 141 mg/kg), copper (1.6 to 134 mg/kg), and lead (3.4 to 169 mg/kg).

3.12.3 OBMUA Phase IA Cultural Resources Survey, February 2005

The Phase IA cultural resource survey was conducted to assess the probability for significant historic or prehistoric archaeological resources within the Area of Potential Effects (APE) for the proposed Laurence Harbor Inceptor in Old Bridge Township. The Phase IA cultural resources survey was limited to the APE in Area 9 and included documentary research, a site visit, and soil borings. The Phase IA cultural resources survey will be used to supplement a Phase 1A cultural resources survey that will be performed for the entire Raritan Bay Slag Site as part of the RI/FS.

3.12.3.1 Documentary Research

The background research indicated that two registered prehistoric sites (28-Mi-19 and 28-Mi-20) lie within or in immediate proximity to the APE. Site 28-Mi-19 was located near Route 35 immediately south of the APE and described as “a camp site on the high point east of [Marquis] creek.” Site 28-Mi-20 was mapped in the proximity of where a dirt road extends to the Raritan Bay shoreline in the general vicinity of the APE and described as comprising of “two small camp sites close together near the bay” containing “oyster shells and flint chips.”

There are 12 registered archaeological sites within 1 mile of the APE. Based on Table 1 in the Phase IA report, 11 sites are shell middens and 1 site was an ephemeral camp. Prehistoric resources near the APE reflect a focus on estuarine resources.

Other archaeological surveys reviewed describe the following information:

- Laurence Harbor on the east site of Cheesequake Creek contained oyster shells, projectile points, ceramic, and bones.
- Site 28-Mo-299 was interpreted as a short-term occupation hunting station or procurement camp.
- Long Neck Creek I site (28-Mo-155) contained artifacts of chert flakes, clam, and oyster shell.
- Historic maps indicate that a possible proposed late-nineteenth-century alignment of the New York and Long Branch Railroad might be located near the Raritan Bay shoreline.

3.12.3.2 Site Visit

A site visit revealed that the site traversed well-drained landforms and wetlands near Raritan Bay. Based on the proximity of the two registered prehistoric sites, there is a high likelihood for prehistoric archaeological resources within the site. The historic archaeological sensitivity was considered moderate to high because of the potential for a rail-line associated with the New York and Long Branch Railroad

3.12.3.3 Soil Borings

Soil borings were conducted by the Environmental Response Contractor and Craig Test Boring to characterize soil and sediment lithology within the APE. Shell fragments were observed in three soil borings (SB3, SB4, and SB14).

3.12.4 OBMUA Phase IB Cultural Resources Survey, April 2005

Based on the findings of the Phase IA cultural resources survey, a phase IB survey was performed. The Phase IB cultural resources survey was conducted to identify potential significant archaeological resources within the APE for the proposed Laurence Harbor Inceptor in Old Bridge Township. The Phase 1B cultural resources survey was limited to the APE in Area 9 and included documentary research and archaeological testing. The Phase IB cultural resources survey will be used to supplement the Phase 1A cultural resources survey that will be performed for the entire Raritan Bay Slag Site as part of the RI/FS.

3.12.4.1 Documentary Research

The documentary research determined that the APE was occupied by Seidler's Beach Hotel from 1905 to 1952. Based on documentary research, no rail-line or transportation-related feature was present within the APE.

3.12.4.2 Archaeological Testing at Systematic Intervals

On March 22 and 24, 2005, archaeological testing was conducted at systematic intervals. A total of 46 shovel test pits were placed at 50-foot intervals and 25-foot intervals within the APE. The pits measured 1.5 feet in diameter and were excavated by round-nosed shovels. Augers were used to attain deep soil samples. No potentially significant archaeological resources were identified.

3.12.5 OBMUA Geotechnical and Hydrogeological Information, April 2007

Results and conclusions from the Geotechnical and Hydrogeological Investigation conducted in the summer 2003 and 2004 were obtained from the Geotechnical and Hydrogeological Information document and the Permit-by-Rule Application Discharge to Groundwater Work Plan (September 2007). The results and conclusions from the investigation conducted in Area 9 are summarized below.

3.12.5.1 Geotechnical Investigation

In July and August 2003 and July 2004, a Geotechnical Investigation was conducted by R3M Engineering which included soil borings and cone penetration tests (CPTs). A total of 16 test borings and 16 cone penetrations tests were conducted to characterize soil lithology. The soil borings were advanced to depths ranging from 25 to 82 feet bgs, and the CPTs were advanced from 43 to 76 feet bgs. CPT dissipation tests were also performed at selected depth intervals in the upper silt stratum at two locations, CPT-14 and CPT-16.

- The horizontal hydraulic conductivities determined in the pore pressure dissipation tests are 1.1×10^{-7} feet per minute (ft/min) at CPT-14 and 3.5×10^{-7} ft/min at CPT-16.

- The pore pressure dissipation results may confirm that the deep portion of the silt stratum is formed by low permeable soils which may be acting as a confining layer between the upper silt stratum and lower permeable sands.

3.12.5.2 Hydrogeological Investigation

In September 2004 a hydrogeological investigation was conducted by R3M Engineering which included slug test analyses and pump test analyses at three monitoring wells, MW-1 through MW-3 in Area 9.

- The hydraulic conductivity estimates for the slug tests are 3.67×10^{-4} ft/min at MW-1, 7.76×10^{-5} ft/min at MW-2, and 1.59×10^{-4} ft/min at MW-3.

- The slug test results indicate that the hydraulic conductivity of the upper silt unit at the project site varied as much as one order of magnitude.

- Groundwater levels in monitoring wells screened across the surficial granular soil and the top of the upper silt unit range from 1.6 to 3 feet above mean sea level (msl) near Raritan Bay.

- In an upland area in the western portion of the site, measured groundwater levels appear to vary seasonally in response to precipitation patterns and ranged from 5.7 feet above msl in September to 10.4 feet above msl in May.

- The water level monitoring results indicate that there is no significant tidal influence on shallow groundwater levels at the well locations in the upper silt stratum.

3.12.6 ATSDR Health Consultation, Raritan Bay Slag Site, February 2009

In November 2008, EPA requested that the Agency for Toxic Substances and Disease Registry (ATSDR) and the New Jersey Department of Health and Senior Services (NJDHSS) evaluate sampling data collected at six areas at the site by NJDEP in November 2007 and for EPA by Weston in September 2008. Surface and subsurface soil, surface water, and sediment samples from Areas 1, 2, 3, 5, 6, and 8 were evaluated.

ATSDR selected the following contaminants for further evaluation:

Areas 1 and 2 - antimony, arsenic, and lead in soil, surface water, and sediment

- Area 3 - antimony and arsenic in soil

- Area 5 - lead in soil

- Area 6 - antimony, arsenic, and lead in surface water

- Area 8 - antimony, arsenic, copper, and lead in soil, surface water, and sediment

Based on observed uses of these areas and evaluation of environmental contamination, NJDHSS and ATSDR determined that children and adults could be exposed to lead at three of the areas at levels that could be harmful to health. The NJDHSS and ATSDR consider Areas 1, 2, and 8 to be Public Health Hazards and Area 5 to be an Indeterminate Public Health Hazard based on the available data.

High lead levels in surface and subsurface soil and in surface water could result in lead exposures of health concern from recreational activities such as sitting on slag and eating and drinking, playing on sand and/or swimming. The NJDHSS recommended that EPA restrict access to the slag area at the base of the park on the waterfront (Area 1), the beach area between the seawall and the first jetty (Area 2), and the Cheesequake Creek Inlet Western Slag Jetty (Area 8).

3.12.6.1 Area 1: Laurence Harbor Seawall

Results from Area 1 indicated that antimony, arsenic, and lead were elevated in some samples in surface soil, surface water, and sediment. The average lead concentration in surface soil was 1,474 mg/kg; this average was driven by one very elevated sample of 10,200 mg/kg which was collected from soil located in a runoff migration pathway between the slag and Margaret's Creek area. Approximately one-half of the surface soil samples contained arsenic, antimony, and lead at levels that exceeded the comparison values (CVs). CVs are human health benchmarks or guidance values that ATSDR uses to screen environmental data. Typically CVs represent estimated contaminant concentrations that are not expected to result in adverse carcinogenic or non-carcinogenic effects. With regard to soils below the surface, samples taken at various depth intervals indicated lead levels exceeded the CV. Half of the subsurface soil samples had lead levels exceeding the EPA Screening Guidance value. The majority of the surface water samples were elevated above the CVs for all metals.

Based on an adult blood lead model estimate, adverse health effects to adults associated with lead exposures to soil from Area 1 are not expected.

3.12.6.2 Area 2: Laurence Harbor Beach (Seawall West end to First Jetty)

Surface soil sampling results indicated a hot spot on the beach where lead levels were elevated, with an average concentration was 526 mg/kg and a maximum hotspot concentration of 1,630 mg/kg. Seven of 12 samples were elevated above the EPA Screening Guidance value for lead. Arsenic and antimony were also elevated in the surface soil samples. These elevated levels appear to be scattered throughout the sampled beach area.

In addition to surface soil sampling in the hotspot in Area 2, EPA collected subsurface samples. The results from limited subsurface lead levels, collected at a depth of 6 to 12 inches and 12 to 18 inches, were very high (649 to 23,800 mg/kg). Arsenic and antimony were also elevated in the subsurface soil samples. Surface water results show that antimony, arsenic, and lead were elevated above CVs for all samples tested.

Based on an adult blood lead model estimate, adverse health effects to adults associated with lead exposures from soil and surface water from Area 2 are not expected.

The blood lead level based on lead contaminated soil and surface water ingestion was evaluated for children aged 12 to 84 months who actively play with the sand and swim at the site. Based on the predicted mean blood level for a child who accessed the site for three months of the year each successive year over a seven year period (1 – 7 years), Area 2 poses a lead hazard to children.

3.12.6.3 Area 3: Laurence Harbor Playground

Only surface soil samples were collected in this area. The majority of the park and playground area soil samples were not elevated; the average soil levels were below the

CVs. Two samples were elevated for arsenic (34 mg/kg and 114 mg/kg); these samples were in the park area. Approximately one fourth of the samples were above the CV for antimony. NJDEP collected three samples from this area and none of the samples were above the CVs.

The theoretical cancer risk from long-term exposure to arsenic is not considered to be significant in Area 3. The non-cancer effects from antimony and arsenic in soil from incidental ingestion in Area 3 is very unlikely.

3.12.6.4 Area 5: Laurence Harbor Beach (First Jetty to Third Jetty)

The area between the first and second jetty in Laurence Harbor has results only for surface soil samples; this area had two samples that were elevated above the lead CV. The results for antimony and arsenic in surface soil were all rejected on the basis of laboratory QA/QC. The NJDEP sampling results are similar to the results obtained from EPA sampling with regard to the average concentration for lead.

Based on the adult blood lead model ATSDR concluded that adverse health effects to adults associated with lead exposures from Area 5 are not expected.

The blood lead level, as contributed by lead contaminated soil and surface water ingestion, was evaluated for children aged 12 to 84 months who actively play with the sand and swim at the site. The report concluded that there is no lead health risk for these age groups from ingesting soil in Area 5.

3.12.6.5 Area 6: Laurence Harbor Beach (Third Jetty West to Eastern Inlet Jetty)

The beach area between the third jetty and the Cheesequake Creek eastern inlet had the lowest contaminant levels for metals in soil and sediment; there were no exceedances above the CVs. The metals in surface water were elevated above the CVs in all samples.

The non-cancer effects from antimony and arsenic in surface water from incidental ingestion during swimming in Area 6 is very unlikely.

Based on the adult blood lead model, ATSDR concluded that adverse health effects to adults associated with lead exposures from Area 6 are not expected.

The blood lead level, as contributed by lead contaminated soil and surface water ingestion, was evaluated for children aged 12 to 84 months who actively play with the sand and swim at the site. ATSDR concluded that there is no lead associated health risk for these age groups from ingesting surface water in Area 6.

3.12.6.6 Area 8: Cheesequake Creek Inlet Western Jetty

The surface soil results from this area show an extremely high concentration of lead (maximum concentration was 198,000 mg/kg). Seven of eight surface soil samples were elevated above the CVs for antimony, arsenic, and lead. The subsurface samples

were elevated with the maximum lead level at 21,500 mg/kg. Surface water samples were elevated for antimony, arsenic, and lead in a majority of the samples.

For children who access the jetty on a regular basis (assuming 5 days a week, 3 months a year), there is a potential for non-cancer health effects from incidental ingestion from soil contaminated with antimony, although this is expected to be unlikely based on the lowest observed effects level (LOAEL) comparison. The likelihood of any potential health effects from incidental ingestion from soil contaminated with arsenic is low. The non-cancer health effects for the incidental ingestion from soil contaminated with copper are very unlikely.

The theoretical cancer risk from long-term exposure to arsenic is not considered to be significant in Area 8. The non-cancer effects from antimony, arsenic, and copper in surface water from incidental ingestion during swimming in Area 8 are very unlikely. The combined ingestion dose from ingestion of soil and ingestion of water while swimming has the potential to cause non-cancer health effects in children for both antimony and arsenic. As illustrated in the ingestion from soil section above, the likelihood is considered to be low.

Since the average soil lead concentration (52,499 mg/kg) is so high, blood lead levels are approximated to be greater than 30 micrograms per deciliter (µg/dL) (P_{10}). Based on comparison to the EPA Screening Guidance value of 400 mg/kg and observed activities such as walking, fishing, clamming, crabbing, sitting on slag, eating/drinking noted in this area, ATSDR concluded that lead-related health effects could result from exposure to adults and children who recreate in Area 8.

3.12.6.7 ATSDR Recommendations

Based on the analysis of the available data, ATSDR made the following recommendations:

- EPA should restrict access to the following areas: the slag area at the base of the park on the waterfront (Area 1), the beach area between the seawall and the first jetty (Area 2), and the Cheesequake Creek Inlet Western Slag Jetty (Area 8).
- EPA should consider re-sampling areas for which laboratory results were rejected.
- The NJDHSS and ATSDR consider Areas 1, 2 and 8 to be Public Health Hazards and Area 5 to be an Indeterminate Public Health Hazard based on the available data.

These recommendations were considered in the evaluation of data gaps and development of recommendations in Section 4.

3.12.7 EPA Side-Scan Sonar and Diver Investigation Survey Letter Report, June 2009

On April 27, 2009, REAC personnel conducted a Side Scan Sonar survey of the inlet to Cheesequake Creek from the Route 35 Bridge extending into Raritan Bay. Using a Marine Sonic Side Scan Sonar equipped with a 600 Kilohertz (kHz) sonar towfish, sonar images were collected of the bottom of the channel. The EPA vessel Kenneth

Biglane was employed to navigate several transects into and out of the inlet. Water depths in the inlet ranged from 5 to 20 feet depending on location and tidal stage.

On April 28, 2009, the survey was continued in the area adjacent to the inlet, approximately 0.25 mile to the northwest and approximately one mile to the southeast, extending approximately 0.25 mile into Raritan Bay. Transects were set up parallel to the shoreline approximately 30 meters apart. Figures 1 through 3 of the EPA Side-Scan Sonar Document, provided in Attachment 11, shows sampling and transect locations, as well as side-scan sonar results.

On April 29 and 30, 2009, EPA-certified divers conducted diving operations in and around the inlet to verify conclusions based on the side scan sonar data and to collect sediment samples from the inlet. Divers conducted seven dives totaling three hours of bottom time.

3.12.7.1 Results of the Side Scan Survey and Diver Investigations

- The side scan survey showed no indication of any items larger than single rocks, fish traps, or discarded tires. No significant rock piles were noted during the survey.

- The main channel of the Cheesequake Creek Inlet is a uniform material (rounded gravel approximately 1 to 2 inches in size) with long axial grooves. The grooves were "v" shaped and approximately one foot in width. Minimal sediment was found in these areas. The main channel composition was homogenous up to the Western Jetty.

- The area southeast of the gravel channel contains sandy material and sand waves created by the changing currents in the inlet. The survey transects that began at S-6 and finished at S-7 showed a transition from a gravel bottom to a much more sandy bottom, indicating that the southwestern area is most likely sand covered. The beach located to the southeast has been depositing sand onto and over the Eastern Jetty.

- A large boulder is located at the toe of the rock jetty, location T-2.

- Boulders at the toe of the slope were large, angular quarry stone covered in algae and many orange sponges. Slag was not observed along the toe of the Western Jetty on the inlet side.

- Horseshoe crabs were observed inside and outside the inlet.

3.12.7.2 Results of the Sediment Sample Analysis

A total of 11 grab samples were collected from the Cheesequake Creek Inlet. Four of the 11 samples (S-9, S-13, S-14, and S-16) contained sediment that was analyzed for TAL metals plus tin. The results are summarized below.

- Analytical results for sediment samples indicate concentrations of seven metals including: Lead (13.9 to 6,950 mg/kg), antimony (5.6 mg/kg to 189 mg/kg), arsenic (3.8 to 118 mg/kg), copper (3.3 to 415 mg/kg), manganese (50.2 to 101 mg/kg), tin (5.6 to 320 mg/kg), and zinc (16.2 to 228 mg/kg).

- The sample collected at the toe of the Western Jetty (S-9) had significantly higher concentrations of antimony, arsenic, copper, iron, lead, and zinc.

3.12.7.3 Recommendations of the Sonar Report

- The side-scan sonar and diver investigation (summarized in Section 3.11 of this Technical Memorandum) was conducted prior to the EPA August 2009 sampling event.

- The side-scan sonar report concluded that two areas have not been fully investigated: the area to the west of the Western Jetty, and the inlet side of the Eastern Jetty. The survey indicates that the inlet side of the Eastern Jetty should contain much more sedimentary material than the Western Jetty. This material was not adequately sampled during the investigation. The area to the outside of the Western Jetty was not sampled during this investigation.

- The side-scan sonar data from the bay portion of the survey indicates that there is an area showing similar surface features to the inlet side of the eastern jetty just as the inlet empties into Raritan Bay. This area may be a depositional area from the Cheesequake Creek which was not sampled.

These recommendations were taken into considering during the data gap evaluation.

3.12.8 EPA Geophysical Survey, July 2009

On April 4, May 11, May 28, and June 8, 2009, Lockheed Martin personnel conducted a geophysical survey of Area 2, Area 3, and the western end of Area 4. Ground penetrating radar (GPR), frequency domain electromagnetic (FDEM) terrain conductivity, and electrical imaging (EI) were used to determine the presence and extent of slag fill material and the thickness of the fill at the Old Bridge Waterfront Park and the beach adjacent to the park. Figures 1 through 6 of the EPA Geophysical Survey, provided in Attachment 12, shows the study areas and corresponding results.

3.12.8.1 Area 2: Results and Observations

- A linear feature of low terrain conductivity, most likely associated with a subsurface utility, crosses the southern end of the beach and lines up with the western manhole.

- Large void spaces between boulders and slag presumed to be used as fill are present.

- Area 2 appears to have a ten-foot layer of slag rich-fill. However, saltwater intrusion may also be contributing to the high terrain conductivity detected by the survey.

3.12.8.2 Area 3: Results and Observations

- A linear feature to each side of a large metal pole southwest of the playground suggests that a subsurface utility may pass through the area. This feature was subsequently identified in a utility mark out performed in April 2010 by the Old Bridge Municipal Utilities Authority as the force main that traverses the area.

- The survey showed typical response of fill material with strong shallow reflector and incoherent reflections below.

3.12.8.3 Area 4: Results and Observations

- Based on variation in conductivity, the survey implies that different types of fill material were used.

- A storm water discharge pipe is present near the surface within Area 4.

3.12.8.4 Conclusions

- Area 2, Area 3, and western end of Area 4 are characterized by high terrain conductivity that is expected to be predominantly slag material.

- Seawater intrusion, particularly for Area 2 and the stormwater outfall in Area 4, may be contributing to high conductivity readings. However, this seawater intrusion is not expected to affect Area 3 and most of Area 4 based on the low conductivity measured in these areas. The observed variation in conductivity suggests that different types of fill material were used, but that fill material with high conductivity dominates.

- The EI profiles for all three areas presented high electrical resistivity near the surface which is indicative of the majority of the site having a layer of fill material composed of large pieces of rock or slag with large voids.

- Boulder-sized fill material (including potential slag) ranges from 10 to 20 feet thick with a soil covering of less than two feet.

3.12.8.5 Findings

The geophysical report recommended that exploratory excavations be performed to verify the geophysical interpretation in areas with both high and low terrain conductivity to verify the content of the fill material (e.g., slag).

The report also recommended that an EI profile(s) be performed in these areas prior to the excavation. This will allow a depth profile correlation between the profile and actual excavation. Test excavations will be performed as part of a test excavation field

investigation in April 2010. EI profiles are not considered to be needed as part of the test excavation field investigation.

3.12.9 EPA Ecological Risk Assessment (2010)

3.12.9.1 Summary

This report presents an assessment of the impact of metals being released and transported from the slag boulders and debris to the biological communities inhabiting and/or utilizing the intertidal zone adjacent to the seawall. EPA 1997 guidance was followed.

3.12.9.2 Findings

- The intertidal zone adjacent to the seawall provides a typical coastal marsh grass (*Spartina*) ecosystem. Shore birds, including Brant's and Canada geese are commonly observed within this intertidal zone.
- The intertidal plant community was dominated by *Spartina* (cordgrass) and *Ulva* (sea lettuce) growing along the entire reach adjacent to the seawall.
- Risk to the intertidal invertebrate community: The following metals had concentration exceeding their respective chronic or acute toxicity benchmarks:
  - Sediment: Arsenic (chronic) and lead (chronic)
  - Pore water: Arsenic (acute and chronic), manganese (chronic), and lead (chronic)
  - Surface water: Arsenic (chronic), copper (acute and chronic), and lead (acute and chronic)
- Impairment of the intertidal zone was indicated based on the low diversity of observed invertebrate fauna and the absence of certain fauna and life-stages.
- Risk to fecundity and early-life stage development of the horseshoe crab (when exposed to arsenic, copper, and lead in sediment, pore water, and surface water): Adult horseshoe crabs are known to come ashore in the bays of Monmouth and Middlesex Counties including Raritan Bay to construct shallow nests within the intertidal zone and lay and fertilize their eggs. Development of the embryos and the larval stages of the horseshoe crab are at risk from metal contamination in sediments, pore water and surface water within this intertidal zone.
- Elevated concentrations of arsenic, chromium, lead, manganese, and nickel were accumulated in *Ulva*. It is anticipated that site-related metals would also be accumulated in *Spartina*.
- Risk to the invertivorous shore birds: Based on dietary exposure models using the semipalmated plover as the receptor and the most conservative exposure parameters (95% upper confidence limit and maximum food intake), arsenic and lead in the sediments were risk drivers.

When using the more representative exposure parameters (mean concentrations and food intake), risk was driven by lead only.

- Risk to the herbivorous shore birds: Based on dietary exposure models using the Canada goose as the receptor and the most conservative exposure parameters, arsenic, chromium, and lead in sediments were the risk drivers. Lead in sediment was also the risk driver when the more representative exposure parameters were used in the model.

- The presence of elemental lead particles (especially at the jetty area) and particles of waste material may pose a risk to all avian receptors. This risk would be the result of ingestion of particles for use within the bird's crop, the same mechanism of exposure which occurs from the ingestion of lead pellets by waterfowl.

Section 4
Data Gap Evaluation

This section identifies gaps in the existing data and provides recommendations for data collection activities to fill the data gaps. A preliminary conceptual site model (CSM) was developed based on the existing information that was reviewed to prepare this technical memorandum. The CSM provides a framework for evaluation of the existing data and development of recommendations. The CSM will be updated and refined as more information becomes available.

As discussed in Section 2, a series of figures (Figures 4-2 through 4-39) were prepared showing sample locations and the distribution of lead and arsenic in environmental media. Sample results are color-coded in the figures to allow identification of results that exceed the screening criteria. Exceedances were further color-coded based on the magnitude of the exceedance relative to other samples in the same medium at the site. Review of the existing data indicated that some data were rejected. Data qualified as "rejected" (R) were neither displayed in the figures nor evaluated in this technical memorandum. All of the remaining data, including data qualified as "estimated" (J), are considered to be valid and are displayed in the figures.

These figures and the data screening reports presented in Appendix A were the primary information sources used to evaluate data gaps. For clarity, the data gap evaluation and associated recommendations are presented by Site Area and, within each Site Area, by environmental media and depth, where applicable. Recommendations that are not related to a specific-site area are discussed as site-wide considerations.

The data were evaluated in sufficient detail to identify data gaps and provide recommendations. Upon finalization of this technical memorandum, details of the technical approach such as specific sample numbers, depths, and locations; chemical analytical parameters and physical measurements; scheduling and sequencing of field activities; data processing and analysis; and reporting will be developed fully in the site-specific work plan and Unified Federal Policy–Quality Assurance Project Plan (UFP-QAPP).

4.1 Preliminary Conceptual Site Model

The major objectives of the technical memorandum are to review and evaluate the existing data and identify data gaps. Broadly speaking, there are four major areas where a comprehensive data set will support the RI and development of feasible remedial alternatives in the FS.

- Identification of source areas
- Chemical fate and transport mechanisms
- Contaminant nature and extent
- Ecological and human health risk assessments

A preliminary CSM was developed to provide a foundation for the evaluations that encompass these four categories. The existing data for each Site Area were reviewed within the framework of the preliminary CSM. Where the existing data are not sufficient to support the RI/FS, recommendations are presented for further investigations. Figure 4-1 provides an overview of the preliminary CSM.

4.1.1 Contaminant Sources

The Raritan slag is a metallic waste from a secondary lead smelter blast furnace (known as kettle bottoms) that was used to augment a seawall and a jetty. Lead was determined to be leaching from the slag under the acidic TCLP conditions and under a neutral salt extraction procedure, considered to represent milder, environmental conditions (Lockheed Martin/REAC 2009). Lead speciation analysis of the slag using XRD showed a greater concentration of lead carbonate in the interior, non-weathered portions of the slag material as opposed to the weathered, outer portions. Lead species on the exterior of the slag included elemental lead (Pb^0), lead carbonate ($PbCO_3$), lead oxide (PbO), lead sulfate ($PbSO_4$), and lead-zirconium oxide ($PbZrO_3$). The oxide, carbonate, and sulfate species are known to have solubilities such that detectable concentrations of lead would be expected in leachate.

Sources of organic contaminants such as VOCs, SVOCs, pesticides, and PCBs have not been identified to date, and thus a preliminary CSM for these classes of contaminants is not presented in this memorandum. Further sampling for organic contaminants, as described in subsequent sections, will determine the presence or absence of organic contaminant source areas. Potential sources of organic contaminants include the potential fill in Areas 1 and 4, which is the subject of test excavation sampling planned for April 2010, and the Margaret's Creek area (Area 9). The CSM will be updated as additional information on sources of organic compounds is collected.

4.1.2 Migration Pathways and Transport Processes

The slag leaching tests and metals speciation results indicate that dissolution from the slag into water is a major pathway for lead into the environment. Direct erosion and release of slag particles is also a pathway. Species of other soluble metal complexes would also be expected to leach from the slag. Dissolved metal species and slag particles will erode into Raritan Bay via the twice-daily flushing of the seawall by the tides and by stormwater runoff. Additionally, groundwater may be in contact with the base of the seawall and dissolve metals. Stormwater runoff may percolate into groundwater and carry dissolved metals. Since density differences cause freshwater to flow on top of saline water in the subsurface, groundwater contaminated by the slag will likely seep to the surface at or above the intertidal zone.

Once in the water column, the dissolved metals will sorb to suspended sediments. A variety of sorption pathways are possible including:

- Sorption to metal oxides (particularly iron and manganese oxides) on the suspended sediments
- Partitioning to organic matter in the sediment

- Ionic exchange with other cations at negatively charged sites on the sediment (such as clay particles)
- Incorporation into the crystalline structure of minerals

A metal's tendency to sorb via these pathways will control its distribution in the sediments. Metals that sorb readily to sediments will likely be found closer to the slag source, whereas those that do not sorb readily will be found in sediments farther from the slag.

Properties of the organic compounds including their water solubility, volatility, and biodegradability are some of the factors affecting the fate and transport of organic contaminants in the environment. Organic compounds detected in sediment and soil samples at the site primarily consist of polycyclic aromatic hydrocarbons (PAHs), pesticides, and PCBs (See Section 4.2.6). These classes of organic compounds tend to have high molecular weight, low aqueous solubility, low volatility, and low biodegradability. As a result, they tend to sorb to the organic carbon fraction of sediment and soil and persist in the environment. Transport of organic compounds sorbed to sediments and soils is a key process affecting their distribution in the environment.

The transport of contaminated suspended sediments will have an impact on transport and deposition of contaminants in Raritan Bay. Contaminants will accumulate in areas where suspended sediments are deposited on the seafloor or beach, generally low-energy environments where current, wind, and wave actions are minimal. At the site, long-shore current and tidal patterns influence sediment transport. With wave and wind action originating from the Atlantic Ocean to the east, and given the northwest trending angle of the shoreline, the long-shore current predominantly flows toward the west. Accretion of sediments on the eastern side of jetties supports the concept that the net near-shore current flow is westward. Therefore, low-energy environments (sediment deposition areas) tend to occur where jetties interrupt the westward-flowing, long-shore current.

Reviews of aerial photographs and sediment/soil data provide evidence for the following low-energy, net depositional zones at the site, as described below.

- The tidal wetlands in Area 9 are likely low-energy, depositional zones.
- Sediments originating in the Area 9 wetlands will be relatively organic-rich due to the decomposition of wetland plants and other organic matter. As these sediments are discharged to the Bay from Margaret's Creek, the long-shore current will carry them westward. It appears that there is a depositional zone for these more organic-rich sediments in front of the eastern half of the seawall.
- In Area 2 and the adjacent Area 5, the shoreline angles more northward and three jetties interrupt the long-shore current, resulting in three depositional zones on the eastern side of each jetty. Although each jetty impedes the

long-shore current, sediments also leak through each jetty and build up on the low-energy western sides.

- Movement in Area 7 is dominated by tidal currents into and out of Cheesequake Creek. As the tide flows out past the slag jetty it carries organic-rich sediments from the Cheesequake wetlands. This Cheesequake Creek discharge into Raritan Bay slows in velocity as the Creek and Bay waters mix. Suspended sediments then drop out of suspension in this lower-energy mixing zone.
- Likewise, as the tide flows in from the Bay into Cheesequake Creek suspended sediments from the Bay are deposited at low-energy locations in the wetland.
- Area 8 is the low-energy side of the slag jetty. The jetties block the long-shore current in this area. Tidal action, wind, and waves will suspend and transport sediment, but to a lesser extent than in other areas subject to the long-shore current.
- Portions of Area 11 are depositional areas. The shoreline appears to be an erosional area protected by boulders or a seawall. However, farther west along the coast, there is a depositional area where the shoreline angles to the north. A beach and mud flats are visible in this area; both are evidence that it is a depositional area within range of the slag jetty.
- Beaches accumulate contaminated sediments transported by the long-shore current, tides, and storms. Accumulation of sediment on beaches occurs where jetties interrupt the long-shore current. This appears to be a significant process at the Area 2 beach, the Area 5 beach, and north of (behind) the Cheesequake inlet western jetty.

Investigation into the following major areas is necessary to develop a more complete CSM and to support the RI, FS, and risk assessments:

- Nature and extent of sediments contamination in Raritan Bay immediately adjacent to the site
- Nature and extent of sediments contamination in Margaret's Creek and the Margaret's Creek wetland
- Information on sediment dynamics, including current profiles, grain size analysis, TOC content, and historical deposition rates
- Risk assessment parameters such as surface water contaminant concentrations; soil and sediment pH, grain size distribution, and TOC; basic water quality parameters, and bioavailability testing (refer to Attachment 13 for more information regarding bioavailability)
- Groundwater flow direction, interaction with surface water, and baseline groundwater quality data
- Identification of sources beyond the seawall and jetty, including metals-containing fill material

Transport of sediments is an ongoing process at the site and it is expected that processes that affect contaminant transport will continue to disperse contaminants in the future. Major events such as strong storms and flooding, can alter the distribution of contaminated sediments, beaches, wetlands, and streams. For example, discussions with Township of Old Bridge officials indicated that strong storms in March 2010 resulted in significant beach erosion. The Township reported a 15-foot wide vertical cut in the beach along the eastern end of Area 6. Site visits by CDM following the storms indicated that a significant amount of sand had accumulated on the eastern side of the Cheesequake Creek eastern jetty. Since the dominant wind and wave direction during the storms was from the northeast, strong wave action would be expected to erode beach sands, transport them off shore, and then transport the sediments generally in a western direction, following the longshore current. This is consistent with the erosion and deposition pattern that was observed after the storm. In addition, heavy rains associated with the storms could transport sediments from the Margaret's Creek wetland area into Raritan Bay and also potentially erode upland soils.

The conceptual model and the evaluation of data gaps below are based on data that is currently available. Although much of the data used in the evaluation is recent, it is important to recognize that the data gap evaluation is limited because of the dynamic nature of the environment of the site.

4.1.3 Potential Receptors

There are a range of potential receptors, both human and ecological, that could be affected by contaminants transported to various environmental media at the site. A brief summary of potential receptors is provided below.

Human Receptors

Significant potential exposure pathways for human receptors are as follows:

- Direct exposure to contaminated soil, sediment, and surface water during recreational activities
- Exposure through consumption of contaminated fish and shellfish
- Exposure to contaminated soil transported via windblown dust

Ecological Receptors

Significant potential exposure pathways for ecological receptors are as follows:

- Direct exposure of organisms to contaminated water, sediment, and soil
- Ingestion of contaminated soil, sediment, and water
- Ingestions of contaminated prey/plants
- Direct uptake of contaminants in soil, sediment, and water by plants

Detailed, site-specific conceptual and exposure models will be developed as part of the human health and ecological risk assessments.

4.2 Site-Wide Considerations

4.2.1 Sediment Characteristics and Dynamics

In order to develop a robust CSM, data are needed to characterize the surface water flow patterns and the sediment dynamics. As discussed above, multiple depositional zones have been identified from the chemical data and a review of aerial photos. However, it will be important to understand the extent and stability of these depositional zones and the potential for currents to disperse contaminated sediments from these areas. Bioturbation could also be a significant factor affecting sediment stability and should be taken into account. Furthermore, for a future evaluation of remedial scenarios at the site including monitored natural recovery, bathymetry and rates of deposition should be determined where feasible. The dynamic nature of the coastal areas will likely preclude an effective geochronology analysis, yet such a study may be possible in the wetland areas shielded from waves. Analysis of sediment grain size and TOC is recommended to assist in understanding sediment dynamics.

4.2.2 Recommendations

- Current meters should be co-located with total suspended solids analysis in strategic locations to characterize both hydraulic flow and sediment movement at the site.
- In order to determine historical deposition rates and the potential for natural recovery, geochronology of sediment cores should be analyzed (where feasible and implementable).
- Sediment samples should be collected to characterize grain size and TOC in the identified depositional zones.
- A bathymetric survey should be conducted in the water Areas (all areas but 3 and 4) in order to further characterize the sediment surface and to assist in the development of remedial alternatives in the FS.

4.2.3 Groundwater/Surface Water Interaction

There are no site-specific data on the interaction of groundwater and surface water at the site. Tidal fluctuations, precipitation events, and the presence of streams and wetlands within the site area can influence the interaction between groundwater and surface water. It is important to understand this interaction, particularly near the seawall and in adjacent areas since the behavior of groundwater and surface water near the seawall can have implications for development of remedial alternatives in the FS.

Installation of sets of shallow and deep, 2-inch piezometers (up to 14 pairs), is recommended to provide data to investigate groundwater/surface water interaction in the vicinity of the seawall and along the length of the site. At least one set of temporary piezometers should be installed on the north side (bayside) of the seawall to determine water levels. The piezometers will be used to obtain water level data that will be used to determine the groundwater flow direction and the horizontal and vertical hydraulic gradient. Proposed water level data collection activities are recommended below.

- Transducers will be installed in three piezometer pairs for a one month period to assess fluctuations in groundwater levels related to tides and precipitation. Water level data will be collected at 10 minute intervals.
- Six rounds of synoptic water level measurements will be collected at one month intervals. During each event measurements will be taken at high tide and at low tide as defined by the closest tidal gauge or at the Cheesequake inlet.
- Tidal data will be obtained from the closest tidal gauging station for the period when transducers are deployed and the synoptic measurements are taken.
- Specific conductance will be monitored in the wells to identify density differences between freshwater and saline water; freshwater head corrections will be made if necessary.

One round of groundwater samples will be collected from the piezometers in Area 1. Shallow groundwater may flow through the base of the seawall in Area 1. In addition, there is information that fill materials, potentially including slag, may be present upgradient (south) of the seawall. Since development of remedial alternatives in the FS may need to consider management of groundwater in Area 1, one round of groundwater sampling is proposed to provide baseline groundwater quality. The following analyses are proposed for the groundwater samples:

- Total metals, including mercury
- Hexavalent chromium
- VOCs, SVOCs, pesticides, PCBs
- Water quality analyses including TOC, total suspended solids (TSS), chloride, hardness, and alkalinity

Groundwater sample analyses will be detailed in the work plan and UFP-QAPP.

Water quality parameters including pH, specific conductance, dissolved oxygen, temperature, salinity, and oxidation/reduction potential (as Eh) will be collected in the field at the time of sample collection. The timing of the sampling event will be determined after the water level data from the transducers and tidal data are evaluated.

A limited number of stratigraphic borings are proposed to be completed at locations near the seawall. Stratigraphic borings will be drilled to characterize the stratigraphic sequence in this area and any shallow groundwater that may be impacted by the slag or fill material. These borings will be completed to the top of the Magothy Formation (estimated to be 50 feet bgs), a regional formation that will likely be the bottom of any shallow aquifer. The borings will provide basic lithologic and geotechnical information on subsurface conditions. Data from the borings will be presented in boring logs and a cross section. To provide a basis for selecting appropriate depths for piezometer screens, the stratigraphic borings will be drilled prior to installation of the piezometers.

4.2.4 Ecological and Human Health Risk

Data needs for the human health and ecological risk assessment were considered in the recommendations provided for the Site Areas discussed below. Some specific data requirements need to be met to support the risk assessments. These include, but are not limited to, the following elements:

- Surface soil samples for human health risk assessment will be collected from 0 to 2 feet bgs and analyzed for metals. A subset (approximately 40 percent) of the samples should be analyzed for organic compounds.
- A subset of the sediment samples 30 percent) will be analyzed for TOC, pH, and grain size distribution to support comparison of the data against screening criteria in the RI.
- Surface water samples will be analyzed for pH, hardness, chloride, and TOC to support comparison of the data against screening criteria in the RI.
- Physical chemical parameters will be collected with all water samples (pH, salinity, Eh, dissolved oxygen, temperature, and turbidity).

Since an ecological risk assessment previously conducted by EPA has not been finalized, it is premature to develop specific recommendations for data collection activities needed to support a Baseline Ecological Risk Assessment (BERA). There are sufficient existing chemical data to support preparation of a SLERA.

Existing biota tissue, pore water, sediment, surface water, and soil data could be used to support a BERA. Previous investigations included the collection of forage fish, mollusk, and aquatic vegetation samples co-located with sediment, pore water and surface water samples. Previous sampling did not include toxicity testing, metals bioavailability testing, or a benthic macroinvertebrate survey. Additional data may be needed to provide the multiple lines of evidence required to support a BERA. If it is determined that a BERA is required, the following types of data are typically needed:

- Sediment/soil toxicity testing data
- Benthic macroinvertebrate community structure survey data
- Sediment pore water chemical analysis data
- Biota tissue analysis data (terrestrial and aquatic)

During the RI field investigation, an ecological reconnaissance, and community aquatic and terrestrial community surveys will be performed to gather information on ecological resources in the area for the ecological risk assessment. Other site-specific surveys may be needed such as avian surveys or fish surveys to support selection of receptor species for the ecological risk assessment.

Based on published wetland maps, there are significant wetland areas within the site boundary, including Area 9 and the open water areas of Raritan Bay. Delineation of the wetlands in Area 9 is recommended.

4.2.5 Background Concentrations

The primary contaminants associated with the known slag source material are metals that also occur naturally in environmental media. Defining background concentrations of contaminants in site media is an important consideration for evaluating the RI data. Some key considerations for background samples include:

- Background samples should have physical characteristics similar to site samples (i.e., similar texture, and basic characteristics such as TOC)
- Background samples should be collected from locations outside of the influence of the site
- There should be a sufficient number of samples to support statistical analysis of the data.
- Analyzed for the same parameters as the site samples and collected early during the RI field activities.

Sediment Background Data

Existing background data exists for sediments from a number of sources:

- Six background samples were collected during the Phase I assessment conducted by Weston Solutions, Inc. for EPA (Weston 2008).

- Six additional background sediment samples were collected during the Phase 2 assessment conducted Weston Solutions, Inc. (Weston 2009).

- Sediment data from a Bay-wide study of Raritan Bay referred to as the REMAP study (EPA 2003). The REMAP data were collected to support an analysis of contaminant trends in Raritan Bay sediments and to develop biological indicators that can be linked to contaminant impacts.

Background samples collected by Weston were collected from an area east of the site (Area 10) as shown on Figure 4-1a. The location appears to be outside of the influence of the site and may be a suitable background sampling location. No information on the physical characteristics of the sediment samples was identified (e.g., grain size, organic content, etc). The background samples were collected from the 0 to 3-inches depth interval, which is consistent with some of the existing sediment sample data, but is not representative of the deeper environmental samples that were collected. In addition, the samples were not analyzed for the same parameters that will be targeted in the future sampling. These sediment samples can be used to represent background conditions for metals but will need to be augmented with additional samples analyzed for the same parameters as the site samples and collected from similar depth intervals.

The REMAP sediment results may be useful for evaluating background sampling results. However, the data were collected from locations covering the entire Raritan Bay and, therefore, it is uncertain whether the data represent site-specific background conditions. In addition, the stated purpose for collecting the samples is to assess contaminant trends in Raritan Bay. The REMAP sediment data will be evaluated further in the work plan to assess their suitability for use as background samples.

Surface Water Background Data
No background surface water samples were identified in the existing data. Additional samples are recommended to define background conditions for surface water. Background surface water samples should be analyzed for the same parameters as the site samples. A detailed recommendation including the potential locations and number of samples will be provided in the work plan.

Soil Background Data
No background data for soil samples were identified in the existing data. Additional samples are recommended to define background conditions for soil. Background soil samples should be analyzed for the same parameters as the site samples. A detailed recommendation including the potential locations and number of samples will be provided in the work plan.

Groundwater Background Data
No background data for groundwater were identified in the existing data. Installation of background monitoring wells is recommended to provide background data to support evaluation of groundwater in Area 1. Background groundwater samples should be analyzed for the same parameters as the site samples.

4.2.6 Organic Contaminants

A subset of the sediment samples were analyzed for organic compounds including VOCs, SVOCs, pesticides, and PCBs. A total of 35 sediment samples from Areas 1, 2, 5, 6, 7, 8, and 11 were analyzed for organic compounds.

Fourteen soil samples collected in the Margaret's Creek area (Area 9) were analyzed for a limited list of organic compounds including PAHs and 4, 4'-DDT.

Screening results for sediment and soil samples are provided in Appendix A. Figure 4-1b provides sample location and screening criteria exceeedences. A summary of the analytical results for organic compounds is provided below.

Sediment Samples

- **VOCs –** Only one VOC, carbon disulfide, was detected in the sediment samples. Carbon disulfide was detected in all of the Site Areas, except Area 6. Concentrations ranged from non-detect to 9.5 µg/kg and frequently exceeded the screening criterion of 0.851 µg/kg. No concentrated area of carbon disulfide detections was identified that would indicate a source area. Carbon disulfide can occur naturally, particularly in reducing environments like sediments.
- **SVOC**s – The SVOCs detected in the sediment samples were almost exclusively PAHs. Concentrations of one or more PAHs exceeded screening criteria in samples from all of the Site Areas that were sampled. The frequency of exceedances was low in samples from Areas 1, 2, 5, and 6. PAH concentrations in Areas 7, 8, and 11 frequently exceeded the screening criteria. The highest concentration of an

individual PAH (pyrene) was 710 µg/kg in a sample collected from Area 11. PAH concentrations do not appear to correlate with the locations of known slag materials or elevated concentrations of lead in sediments. PAHs are widespread in the environment.

- **Pesticides –** Five pesticides were detected at concentrations exceeding screening criteria including, heptachlor epoxide, dieldrin, 4,4'-DDT and its degradation products 4,4'-DDE, and 4,4'- DDD. The vast majority of the exceedances were for 4, 4'-DDT and its degradation products. Although pesticide concentrations exceeded applicable screening criteria, concentrations generally were low. EPA banned the use of DDT in the United States in 1972. The greatest frequency of exceedances occurred in samples collected from Site Areas 2, 7, and 11.
- **PCBs – Only** one PCB (as the commercial mixture Aroclor-1254) was detected in the sediment sample**s**. Aroclor-1254 exceeded its screening criterion of 23 µg/kg in 8 of the 35 sediment samples including samples from Areas 2, 5, 7, 8, and 11. The maximum concentration of Aroclor-1254 (480 µg/kg) occurred in a sample collected from Area 2.

Margaret's Creek Soil Samples
SVOCs – With one exception, SVOCs that exceeded soil screening criteria were PAHs. PAH concentrations detected in the soil samples were low (maximum concentration of 0.25 µg/kg**)**. Bis-2-ethyhexyl phthalate was detected at a concentration of 2.1 µg/kg in one sample.

4.2.7 Recommendations for Organic Analyses

Although concentrations of organics exceeded the screening criteria in some samples, overall the concentrations were low. In general, many of the organic compounds detected in soil and sediment samples such as DDT and its degradation products and PAHs are widely distributed in the environment. Further, organic compounds are not known to be associated with the slag sources (i.e., seawall and Cheesequake Creek western jetty) at the site. For these reasons, limiting organics analysis to 40 percent of future samplesis recommended to characterize organics contamination.

Given that there are potential contaminant sources other than the slag jetty and seawall contributing to contamination in the Margaret's Creek wetland (Area 9), 100% of locations will be analyzed for organics in Area 9. Similarly, as part of the test excavation investigation that will be conducted in Areas 1 and 4 during April 2010, 100 percent of the soil samples will be analyzed for VOCs, SVOCs, pesticides, and PCBs.

4.2.8 Sediment and Soil Analyses

The following analyses for the sediment and soil samples are recommended to identify the nature and extent of contamination from the slag and any other unknown sources, as well as provide information for the CSM, RI, and FS:

- Total metals, including mercury
- Hexavalent chromium
- VOCs, SVOCs, pesticides, PCBs (40 percent of samples)

- TOC, pH, grain size distribution (30 percent of samples in each area)
- Geotechnical parameters in selected areas to support the FS

Soil and sediment analyses will be detailed in the work plan and QAPP. Recommended analyses for surface water samples are provided in the individual sections below.

4.3 Cultural Resources Survey

A cultural resources survey was conducted previously in the Margaret's Creek Area. However, a cultural resources survey needs to be prepared for the other Site Areas. In accordance with the National Historic Preservation Act (NRHP), a cultural resources survey will be performed to determine the presence or absence of cultural resources that may be impacted by the implementation of the RI and remedial action.

4.4 Topographic Survey

A detailed topographic survey has not been prepared for the site and the surrounding area. A detailed topographic survey is recommended to provide basic topographic information to support the RI and FS. The topographic map will be incorporated into the GIS and will serve as a site base map. The map will be prepared at a topographic resolution sufficient to support the FS and will be useful for subsequent remedial design and remedial action activities.

4.5 Area 1: Laurence Harbor Seawall

4.5.1 Sediment Data Gaps

Figures 4-2 and 4-3 show the locations of sediment samples collected from Area 1. The seawall in Area 1 is a known major source of metals. Area 1 contains two depositional zones: an eastern zone where organic-rich sediments from Margaret's Creek are likely deposited, and a western zone formed by the jetty in Area 2.

The data show that arsenic contamination is more wide-spread laterally than lead contamination, suggesting that lead has a higher affinity for sediment than arsenic. The locations with the highest concentrations were in the near-shore area in the eastern depositional zone. The off-shore row of samples shows that lead contamination is well delineated; however, arsenic is still elevated. For the deeper intervals, there are only two results for lead that exceed the 30.2 ppm screening limit. These locations are both directly adjacent to the slag. For arsenic, concentrations are overall lower than the shallower interval, yet vertical delineation is not complete in the depositional zones.

4.5.2 Sediment Recommendations

- Collection of additional sediment samples is recommended to delineate arsenic contamination further off-shore beyond the last row of existing samples.

- Deeper sediment samples are recommended to delineate the vertical extent of contamination in depositional zones.

4.5.3 Surface Water Data Gaps

Figures 4-4 and 4-5 show the locations of surface water samples collected from Area 1. Limited surface water sampling was conducted for dissolved and total metals in the near-shore areas near the slag seawall and adjacent to the mouth of Margaret's Creek. Lead concentrations exceeded the screening level of 8.1 µg/L in each sample for both dissolved and total surface water samples. Dissolved arsenic samples were below the screening level in all locations; two of nine total arsenic samples exceeded the screening level.

4.5.4 Surface Water Recommendations

To support the RI and risk assessments, a limited number of surface water samples should be collected concurrently with sediment samples during future sediment sampling events. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, dissolved organic carbon (DOC), and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.5.5 Soil Data Gaps

Surface soil samples were not collected from the sandy area above the seawall, between the seawall and Area 4. This area is located close to the seawall and the potential exists that contaminants associated with slag in the seawall may impact the adjacent soils.

4.5.6 Soil Recommendations

Additional surface soil sampling is recommended to characterize Area 1 surface soils and provide data for the RI and risk assessments. Test excavations and subsurface soil sampling are currently planned in Areas 1 and 4 to determine whether buried slag is present and to investigate subsurface soil contamination. Prior to conducting the test excavations, one surface soil sample will be collected at each of the 12 test excavation transects. .

4.6 Area 2: Laurence Harbor Beach

4.6.1 Sediment Data Gaps

Figures 4-6 and 4-7 show the locations of sediment samples collected from Area 2. Area 2 is a net depositional zone due to a jetty and the angle of the shoreline. Due to the Area's proximity to the slag seawall in Area 1 and the direction of the long-shore current, it would be expected that sediments in this area would be highly contaminated in both the shallow and deep intervals. The data indicate that this is generally true. The highest concentrations were found in the shallower sediments closest to the high tide line. Many results from the deeper intervals are above the screening levels, indicating insufficient vertical delineation. Furthermore, contaminant concentrations in the line of off-shore samples are elevated, indicating incomplete lateral delineation.

4.6.2 Sediment Recommendations

- Deeper samples are recommended across Area 2, especially directly against the jetty, at the crook of the jetty and beach, and on the beach.
- Additional sampling is recommended for the areas off-shore of Area 2.

4.6.3 Surface Water Data Gaps

Figures 4-8 and 4-9 show the locations of surface water samples collected from Area 2; limited sampling was conducted for dissolved and total metals. Concentrations were significantly elevated in both sample types for both lead and arsenic. The data indicate that substantial partitioning is occurring from the sediments into the water column.

4.6.4 Surface Water Recommendations

To support the RI and risk assessments, a limited number of surface water samples should be collected concurrently with sediment samples during future sediment sampling events. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, DOC, and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.6.5 Soil Data Gaps

Figure 4-10 shows the locations of surface soil samples collected from the Area 2 beach. Overall, lead and arsenic concentrations in this area are elevated, with higher concentrations occurring near the shoreline and decreasing in the upland direction.

The highest concentrations of lead and arsenic occur along the high tide strand line, which is visible in the aerial photograph. The Area 2 beach appears to be accreting. The jetty at the western end of the Area 2 causes sand carried by the westward long-shore current to be deposited on the beach. Thus, metal-bearing material derived from Area 1 accumulates on the Area 2 beach, burying older material. Since the slag has been at the site for over 30 years, it is possible that the older, buried soils also contain elevated concentrations of metals.

4.6.6 Soil Recommendations

- Subsurface soil sampling is recommended over the entire Area 2 beach to determine the vertical extent of contamination. The samples should be collected from the same locations as the surface soil samples.
- The existing surface soil data is considered adequate to define the nature and extent of contamination in the surface soils.

4.7 Area 3: Laurence Harbor Playground

4.7.1 Soil Data Gaps

Figure 4-11 shows the locations of surface soil samples collected in Area 3. Much of Area 3 is a children's playground located just south of the Area 1 seawall. A fence separates the playground from the seawall. Surface soil data collected in this area indicate generally low levels of lead and arsenic, with a few locations showing elevated lead and arsenic concentrations. ATSDR's health consultation (ATSDR 2009) indicated that there is no apparent public health threat for the playground, based on the available data.

Although soil samples were collected from the playground, no samples were collected in the area between the playground and the Area 2 beach, where higher levels of lead and arsenic occur in soil. It is likely that this area is used in conjunction with playground activities.

4.7.2 Soil Recommendations

Additional surface (0 to 2 feet) soil sampling is recommended for the area immediately west of the playground, between the playground and the Area 2 beach.

4.8 Area 4: Old Bridge Waterfront Park

4.8.1 Soil Data Gaps

Figure 4-12 shows the locations of surface soil samples collected from Area 4; limited soil sampling (7 samples) was conducted. Samples were collected along the walkway on the south side of the fence that separates Area 4 from Area 1. Lead concentrations exceeded 30 mg/kg in the majority of samples. With the exception of one location immediately adjacent to the seawall, arsenic concentrations were in the range of 0.389 mg/kg to 10 mg/kg. Test excavations are currently planned in Areas 1 and 4 to investigate whether buried slag is present.

4.8.2 Soil Recommendations

Additional surface soil sampling is recommended for Area 4 to provide a more complete data set for the RI and human health risk assessment. Test excavations are currently planned to determine whether buried slag is present in Areas 1 and 4. Soil samples will be collected from the test excavations. A total of 12 surface soil samples, one at each transect location, will be collected in conjunction with the test excavation sampling. The need for additional surface soil samples in these areas will be evaluated based on the results of the test excavation sampling.

4.9 Area 5: Laurence Harbor Beach between the First and Third Jetties

4.9.1 Sediment Data Gaps

Figures 4-13 and 4-14 show the locations for sediment samples collected from Area 5. Area 5 contains three separate jetties, roughly dividing the Area into two halves. It appears that as the long-shore current flows westward, sediment from Area 2 has

washed over or through the eastern-most jetty and deposited on the eastern half of Area 5, particularly near the high-tide line. While the western half is noticeably a depositional zone, the contamination is of a lesser magnitude than in the eastern half. A likely scenario is that wash-over from the eastern half occurs, and the contaminated sediments mix with cleaner sediments being deposited directly from Raritan Bay.

A limited number of samples in the row furthest off-shore had lead concentrations above the screening criterion. The deeper intervals are above the screening level generally along the high-tide line and near the eastern jetty where washed-over sediments from Area 2 would be expected.

4.9.2 Sediment Recommendations

- Additional sediment sampling is recommended to delineate contaminated depositional zones off-shore.
- Additional sediment sampling is recommended to support vertical delineation in the area between the central and eastern jetty.

4.9.3 Surface Water Data Gaps

Figures 4-15 and 4-16 show the locations of surface water samples collected from Area 5; limited sampling was conducted in the near-shore areas. Dissolved arsenic levels were below the screening level for all samples, and 50 percent of the total arsenic samples were above the screening level. Dissolved lead levels were above the screening level in all but one sample, with significantly greater concentrations found in samples analyzed for total lead.

4.9.4 Surface Water Recommendations

To support the RI and risk assessments, a limited number of surface water samples should be collected concurrently with sediment samples during future sediment sampling events. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, DOC, and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.9.5 Soil Data Gaps

Figure 4-17 shows the locations of soil samples collected from Area 5. All of the soil samples from Area 5 were collected from depths less than 12 inches. Area 5 is bordered on the east and west by jetties. A third jetty divides Area 5 into two beaches. The eastern beach is adjacent to Area 2, which had elevated levels of lead and arsenic in soil. Lead and arsenic concentrations in Area 5 show a decreasing trend moving from east to west, which is consistent with transport of sediment from Areas 1 and Area 2 by the westward long-shore current and the tidal action of the bay. Nearly all of the soil samples collected from the eastern beach had elevated concentrations of lead and arsenic. In contrast, at the western beach, lead and arsenic concentrations generally were lower.

4.9.6 Soil Recommendations

- The vertical extent of contamination has not been defined in the eastern portion of Area 5. Subsurface soil samples should be collected within the entire eastern beach area to determine the vertical boundary of contamination. Sample locations should extend to the western side of the middle jetty.
- The southern boundary of the horizontal extent of soil contamination (south of the walkway) has not been defined in the eastern section of Area 5. A limited number of soil samples are recommended in the area south of the walkway to determine the southern boundary of soil contamination.

4.10 Area 6: Laurence Harbor Beach between the Third Jetty and Cheesequake Creek Inlet Eastern Jetty

4.10.1 Sediment Data Gaps

Figures 4-18 and 4-19 show the locations of sediment samples collected from Area 6. Area 6 is bounded by the eastern Cheesequake Creek jetty to the west, and a jetty to the east. Minimal deposition appears to be occurring in this area. Sediments entering this area are either likely from Raritan Bay or are washed over the eastern jetty from the less-contaminated half of Area 5. There are only sporadic exceedances of the screening level for lead in the shallower intervals, and arsenic concentrations are generally between 0.389 mg/kg and 10 mg/kg, with just one instance of a higher concentration. Samples from the deeper interval had only one exceedance for lead. However, the deeper intervals were on average more contaminated with arsenic.

4.10.2 Sediment Recommendations

Additional deep sediment (greater than 24 inches) samples are recommended for the eastern half of Area 6 to delineate the vertical extent of arsenic contamination observed in the deeper sediment samples.

4.10.3 Surface Water Data Gaps

Figures 4-20 and 4-21 shows the locations of surface water samples collected from Area 6. Three total and dissolved metals samples were collected in the off-shore eastern portion of Area 6 and three samples were collected in the near-shore western portion. Lead was elevated for all the samples. For arsenic, only one of the off-shore samples was elevated, whereas all three near-shore samples were elevated.

4.10.4 Surface Water Recommendations

Limited surface water sampling was conducted in Area 6. Additional surface water sampling is recommended to provide greater coverage in Area 6. To support the RI and risk assessment, a limited number of surface water samples should be collected in conjunction with the additional sediment sampling recommended in Section 4.10.2. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, DOC,

and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.10.5 Soil Data Gaps

Figures 4-22 and 4-23 show the locations of soil samples collected from Area 6, from the 0 to 12-inch and greater than 12-inch intervals, respectively. The majority of the soil samples were collected along the western half of the beach and from depths less than 12 inches. Three samples were collected from depths greater than 12 inches.

Lead and arsenic concentrations in the soil samples were consistently low, with most concentrations in the range of 0.0537 to 30 mg/kg for lead and 0.389 to 10 for mg/kg for arsenic. Beach accretion does not appear to be a significant process in Area 6 and, therefore, transport of metals derived from slag along the seawall and subsequent deposition on the beach is not expected.

4.10.6 Soil Recommendations

- Although the concentrations of lead and arsenic in soil samples from Area 6 generally were low, no samples were collected from the eastern half of the beach. A line of surface soil samples along the eastern half of the Area 6 beach is recommended to provide data to evaluate soils along the entire length of the beach.
- Subsurface sampling is recommended for a subset (estimated at 50 percent) of the locations to delineate the vertical extent of contamination.

4.11 Area 7: Cheesequake Creek Inlet

4.11.1 Sediment Data Gaps

Figures 4-24 and 4-25 show the locations of sediment samples collected from Area 7. Area 7 comprises the Cheesequake Creek inlet and a limited off-shore area. The western jetty creating the inlet was built of slag, and thus elevated concentrations would be expected in this area. Ebb tides will bring relatively organic-rich sediments from the Cheesequake Creek wetland through the Inlet; once the tidal flow reaches Raritan Bay, dispersion causes the flow's energy to decrease, allowing sediments to drop out of suspension. Flood tides will bring water and suspended sediment into Cheesequake Creek from Raritan Bay.

Wash-over from the eastern (non-slag) jetty from Area 6 has created a sandbar in the Inlet. Tidal scour has left only gravel on the seafloor in other portions of the Inlet proper. As a consequence of these conditions, only the deposition area in Raritan Bay was sampled extensively. Elevated concentrations of both arsenic and lead are present in both the deeper and shallow samples in this zone. Delineation is not complete as the outer-most samples are elevated. No data are available for areas south of the Route 35 Bridge in Cheesequake Creek.

4.11.2 Sediment Recommendations

- Additional sediment samples are recommended to further delineate the depositional zone offshore of the slag jetty.
- The vertical extent of sediment contamination has not been defined. Additional subsurface sediment samples are recommended in the off-shore depositional area.

4.11.3 Surface Water Data Gaps

No surface water samples were taken in this area.

4.11.4 Surface Water Recommendations

No surface water samples were collected in Area 7. To support the RI and risk assessments, collection of surface water samples is recommended in conjunction with the additional sediment sampling described in Section 4.11.2. A limited number of surface water samples should be collected in conjunction with the additional sediment sampling recommended. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium , TOC, DOC,and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.11.5 Soil Data Gaps

Figure 4-26 shows the locations of soil samples collected in Area 7. A total of 5 samples were collected from the sandy area on the northwestern side of the eastern Cheesequake Inlet jetty. This area may be a depositional area resulting from wash-over of the eastern jetty by tides and storms.

Arsenic data are not available for the soil samples collected from Area 7; however, the lead concentrations are marginally elevated (0.537 to 30 mg/kg). Soil samples collected from the adjacent area (Area 6), the likely source of sand during wash-over events, also show low concentrations of lead and arsenic, generally 0.0537 to 30 mg/kg and 0.389 to 10 mg/kg, respectively.

4.11.6 Soil Recommendations

Since quality-controlled arsenic concentrations were not available from prior investigations, further sampling is recommended for this area.

4.12 Area 8: Cheesequake Creek Inlet Western Jetty

4.12.1 Sediment Data Gaps

Figures 4-27 and 4-28 show the locations of sediment samples collected in Area 8. Area 8 is directly adjacent to the slag jetty that forms the Cheesequake Creek Inlet. Since much of this area is shielded from the long-shore current due to the inlet's jetties, dispersion of contamination is likely to be a slow process and consequently contamination will have built up over time. Contamination in the shallow intervals is

widespread, with several very high values. A similar pattern to Area 1 is evident, in that arsenic contamination has dispersed farther from the slag source than the lead. The deeper intervals are also very contaminated, although levels are lower in the northwest portion of the Area.

4.12.2 Sediment Recommendations

- Deeper sediment samples are recommended to provide further vertical delineation across most of Area 8
- Additional sediment sampling is recommended to define the horizontal and vertical extent of contamination near the end of the Cheesequake Creek western jetty.

4.12.3 Surface Water Data Gaps

Figures 4-29 and 4-30 show the locations of surface water samples collected from Area 8. Five surface water samples were taken: three along the slag jetty (likely above a gravel bed) and two in the near-shore area in a sediment area. Elevated dissolved and total concentrations of lead and arsenic were found solely in the sediment area, affirming that partitioning is occurring between contaminated sediments and the water column.

4.12.4 Surface Water Recommendations

To support the RI and risk assessments, a limited number of surface water samples should be collected concurrently with the additional sediment sampling described in Section 4.12.2. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, DOC, and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.12.5 Soil Data Gaps

Figure 4-31 shows the locations of surface soil samples collected in Area 8 along the western jetty and on the beach area behind the jetty, close to the water. Soil sampling was limited in Area 8, consisting of only 7 samples, all of which show elevated concentrations of both arsenic and lead. The location of the soil samples close to the shoreline and the elevated concentrations suggest that metals from slag at the western jetty have affected surface soil on the adjacent areas, either through deposition during high water or by sedimentation in the more quiescent environment behind the jetty.
The lateral and vertical extent of contamination in Area 8 has not been adequately defined. It is likely that slag-related contamination extends further up the beach, toward the southwest and along the jetty.

4.12.6 Soil Recommendations

Additional soil sampling is recommended to characterize the lateral and vertical extent of soil contamination in Area 8. Sampling is proposed to extend

from the edge of the bay to the southwest, toward Route 35, and along the western jetty.

4.13 Area 9: Margaret's Creek

4.13.1 Sediment Data Gaps

Figures 4-32 and 4-33 show the location of sediment samples in Area 9. Area 9 comprises an inland tidal wetland, Margaret's Creek (that connects the wetland hydraulically to Raritan Bay), an elevated dirt roadway in the wetland, and beachfront in front of the wetlands. The wetland likely contains fill material; it is unknown if significant slag material is present in the wetlands.

As discussed for Area 1, organic-rich sediments likely flow out of the wetland to the bay via Margaret's Creek on ebb tides. These sediments are deposited near the mouth of the Creek and farther west in front of the slag seawall. Given the westward long-shore current, it is unlikely that contamination from the seawall or re-suspended sediments from this depositional zone will travel eastward, against the long-shore current, onto the Area 9 beachfront. The data indicate that lead concentrations are not elevated along the beachfront, and slightly elevated concentrations of arsenic occur sporadically. Flood tides could carry re-suspended contaminated sediments into the wetlands. There are only two sediment samples in the wetlands; both exceeded the screening criteria for lead and arsenic.

4.13.2 Sediment Recommendations

- Another line of samples off-shore of the beachfront is recommended to delineate the slightly elevated arsenic levels.
- Further sampling is recommended near the mouth of Margaret's Creek (and near the border of Area 1).
- Additional wetland sediment sampling is recommended for the entire wetland area, including the open water in the wetland. Surface samples (0 to 6 inches) and deeper samples, to a depth of at least 4 feet are recommended for this area.

4.13.3 Surface Water Data Gaps

Figures 4-34 and 4-35 show the locations of surface water samples in Area 9. Four surface water samples were collected along the beachfront area and three were collected along Margaret's Creek. Lead concentrations were above the screening level in all but one of the samples, which had high numbers in the Margaret's Creek samples.

4.13.4 Surface Water Recommendations

- Additional surface water sampling is recommended for Margaret's Creek. Surface water samples should be collected on the incoming and outgoing tides to provide data to assess whether metals contamination is being transported from the wetland and/or the sediments and sources associated with the seawall.

- Limited surface water sampling is recommended in conjunction with collection of sediment samples in the open water areas of the Margaret's Creek wetland.
- Analysis should be conducted for total and dissolved metals, hexavalent chromium, TOC, DOC, and physicochemical properties including dissolved oxygen, pH, Eh, temperature, salinity, and turbidity.

4.13.5 Soil Data Gaps

Figures 4-36 and 4-37 show the locations of soil samples collected in the Margaret's Creek area (Area 9). Soil data for Area 9 was stratified by depth as follows:

- Surface soil samples collected as deep as 2 feet
- Subsurface soil samples collected at depths greater than 2 feet

Samples were collected in two major areas within Area 9: from the beach area and along a pipeline right-of-way by OBMUA contractors. The area surrounding the samples collected along the right-of-way appears to have been filled in the past and is elevated above the level of the surrounding wetland. Previous investigation have noted crushed battery casings in this area.

Beach Area

- Lead and arsenic concentrations in the beach area generally were low. Most samples had concentrations of lead and arsenic less than 30 mg/kg and less than 10 mg/kg, respectively.
- Two samples, located adjacent to Margaret's Creek and southwest of the beach area, had elevated levels of both lead and arsenic. These samples are located near debris and kettle bottoms (slag) observed in this area.
- The beach area does not appear to have been affected by metal contaminants derived from slag material associated with the seawall in Area 1 or by transport of metals in soil along the right-of-way in Margaret's Creek.

Right-of-Way

- Concentrations of lead and arsenic in surface soils along the right-of-way are markedly higher than in soils in the beach area. In particular, lead concentrations range between 30 and 500 mg/kg in half of the samples collected along the right-of-way and the lead concentrations exceed 500 mg/kg in three of the samples.
- Arsenic and lead concentrations are elevated in subsurface soils along the dirt road in the right-of-way. The subsurface soil data suggest that arsenic contamination is at depth in this area. The deepest samples in this area were 8.5 feet bgs.

4.13.6 Soil Recommendations

- No additional soil sampling is recommended for the beach in Area 9. The data are adequate to define the nature and extent of contamination in the beach soils.
- Additional soil sampling is recommended to investigate soil contamination in the Margaret's Creek area. The existing data are not sufficient to define the lateral or vertical extent of contamination in this area. Both surface and subsurface soil sampling are recommended within the fill area that is elevated above the surrounding wetland. Systematic soil sampling, such as grid sampling, is recommended to investigate soil contamination. Soil sampling would be done in conjunction with wetland sediment sampling recommended for Area 9 (see Section 4.13.2).

4.13.7 Groundwater Data Gaps

Three monitoring wells, located in Area 9, were sampled during the OBMUA investigation of metals contamination related to installation of a pipeline in the right-of-way. The three wells were located along the right-of-way and were installed within the shallow groundwater. Samples were analyzed for metals.

A number of metals exceeded New Jersey Groundwater Quality standards (NJGWQS) including iron, manganese, sodium, aluminum, beryllium, and arsenic. Arsenic (at 5.1 µg/L) marginally exceeded the NJGWQS of 3 µg/L in one of the monitoring well samples.

4.13.8 Groundwater Recommendations

Further investigation of the groundwater chemical quality and hydrogeology will likely be needed in Area 9. However, it is recommended that the groundwater investigation in this area be deferred until the additional soil, sediment, and surface water sampling recommended above is complete, the associated data are reviewed, and site-specific stratigraphic information is available. These data will provide a rational basis to determine the locations and depths of monitoring wells in this area. Details regarding the sequencing and scheduling of the groundwater investigation in the Margaret's Creek area will be provided in the work plan.

4.14 Area 10: Historical Background Sampling Area

4.14.1 Data Gaps

Area 10 is the background sediment sample locations identified by Weston in the Phase 1 and Phase 2 investigations. The existing data were not screened against background data at this time. Section 4.2.5 includes a preliminary discussion and recommendations for collection of background samples.

4.15 Area 11: Depositional Area

4.15.1 Sediment Data Gaps

Figures 4-38 and 4-39 show the locations of sediment samples collected from Area 11. Area 11 is similar to Area 8 in that the jetties on the Cheesequake Creek inlet shield the

area from the long-shore current. However, much of Area 11 is not shielded from wind and waves from Raritan Bay. Two patterns emerge from the data for Area 11. The first is that the slow dispersion of arsenic seen in Area 8 extends into the sections of Area 11 closest to Area 8. The second pattern is that wind and wave action appears to be driving sediment closer to the shore.
Slightly elevated concentrations of arsenic and lead are present in the near-shore area. Slight shifts in wind direction, and periodic long-shore currents could develop to transport these sediments farther westward to an apparent depositional area approximately 0.5 mile up the coastline.

Vertical delineation is not complete in the section adjacent to Area 8, and the central and near-shore portions of Area 11 lack sufficient samples for delineation. Furthermore, the depositional zone up the coast has not been sampled and may be receiving contaminants from the site.

4.15.2 Sediment Recommendations

- Additional sediment samples are recommended to further delineate the lateral and vertical extent of contamination in the central portion, in the near-shore, and in the near-shore areas northwest of Area 11.
- Samples should be collected in the depositional beach area approximately 0.5 mile west along the coastline from Area 11.

4.15.3 Surface Water Data Gaps

No surface water samples were collected in this area.

4.15.4 Surface Water Recommendations

To support the RI and risk assessments, a limited number of surface water samples should be collected concurrently with sediment samples describe in Section 4.15.2. Surface water analyses should include total and dissolved metals in order to permit comparisons with water quality criteria and provide information for the further development of the CSM. Other analyses include hexavalent chromium, TOC, DOC, and physicochemical properties including dissolved oxygen, pH, temperature, salinity, and turbidity.

4.15.5 Soil Data Gaps

No soil sampling was conducted in this area.

4.15.6 Soil Recommendations

Soil sampling is recommended along the shoreline adjacent to Area 11 since contaminated sediments in this area could also affect the shoreline area.

4.16 Next Steps

When the scope of work for the RI/FS is finalized, the project planning documents and activities detailed below will be performed.

Work Plan

The RI/FS Work Plan will include a comprehensive description of project tasks, project documentation, and a project schedule. Specifically, the Work Plan will include the following:

- Identification of RI/FS project elements including planning and activity reporting documentation.
- A technical approach for each task to be performed, including a detailed description of each task; the assumptions used; any information to be produced during and at the conclusion of each task; and a description of the work products that will be submitted.
- A schedule with dates for completion of each required activity, critical path milestones and submission of each deliverable required by the SOW and the anticipated review time.
- Issues relating to management responsibilities, site access, site security, contingency procedures and storage and disposal of investigation derived wastes (IDW) will also be addressed.
- A list of key CDM personnel who will support the project and the subcontractor services required to complete the work.

Estimated costs for the RI/FS will be prepared, including a detailed cost breakdown of direct costs, subcontract costs, and other direct costs.

UFP-QAPP

A UFP-QAPP will be prepared in accordance with the Uniform Federal Policy for QAPPs. The QAPP will describe the project objectives and organization, functional activities, and QA/QC protocols that will be used to achieve the required data quality objectives (DQOs).

The QAPP will include sample locations and frequency; a list of sampling equipment; personnel and equipment decontamination procedures; sample handling and analysis; and a breakdown of samples to be analyzed. The QAPP also addresses site management including site control and site operations. The logistics of all field investigation activities will also be described.

The site operations section includes a project organization chart and delineates the responsibilities of key field and office team members. A schedule will be included that shows the proposed scheduling of each major field activities.

Accident Prevention Plan (APP)

Draft and final APPs will be prepared for the field investigation. The APP will be prepared concurrently with the UFP-QAPP. The APP will be submitted as a separate deliverable. The APP includes the following site-specific information:

- A hazard assessment
- Training requirements and training topics
- Definition of exclusion, contaminant reduction, and other work zones
- Monitoring procedures for site operations

- Safety procedures
- Personal protective clothing and equipment requirements for various field operations
- Disposal and decontamination procedures

Subcontractor Procurement

All subcontractors needed to complete the field investigations will be procured. Procurement activities include: preparation of the technical statement of work; preparation of Invitation for Bid (IFB) or Request For Proposals (RFP) packages; conducting a pre-bid site visit (when necessary); answering technical and administrative questions from prospective bidders; performing technical and administrative evaluations of received bids; performing the necessary background, reference, financial and insurance checks; preparation of consent packages for approval by the USACE; and awarding the subcontracts.

Mobilization and RI Field Activities

Following approval of the final project planning documents, mobilization activities will be completed. Mobilization consists of site preparation, access support, field personnel orientation, field trailer and equipment mobilization, and field supply ordering, staging and transport to the site for the field activities. As part of mobilization, field planning meetings will be conducted with site personnel.

[5] Screening criteria are the lowest values

mg/kg - milligrams per kilogram
µg/kg - micrograms per kilogram
ca - value based on cancer effects
n - value based on noncancer effects
m - concentration may exceed ceiling limit
s - concentration may exceed saturation concentration

a - freshwater value used as directed
b - value for total DDT
c - value for BHC
d - value for chlordane
e - value for total PCBs

R2-0000144

[8] EPA 2003. EPA Region 5 Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels.
[9] Screening criteria are the lowest values

mg/kg - milligrams per kilogram
µg/kg - microgram per kilogram
NL - not listed
NA - not applicable or not available
PQL - practical quantitation level
DL - detection limit
- criteria for PCBs
- criteria for endrin
- criteria for beta-BHC
- criteria for mixture of 2,4-dinitrotoluene and 2,6-dinitrotoluene
* - based on natural background levels as noted in NJDEP criteria
** - value for 1,3-dichloropropene

ca - value based on cancer effects
n - value based on noncancer effects
m - concentration may exceed ceiling limit
s - concentration may exceed saturation concentration
a - value for chromium (trivalent)
b - value for DDT and metabolites
c - value for chlordane
d - value for PCBs
f - value for low molecular weight polyaromatic hydrocarbons
g - value for high molecular weight polyaromatic hydrocarbons

R2-0000153

[5] Screening criteria are the lowest values

R2-0000156

Table 2-4
Groundwater Screening Criteria
Raritan Bay Slag Superfund Site
Old Bridge and Sayreville, New Jersey

CAS Number	Chemical Name	7/08 NJ Groundwater Quality Standards Class IIA Water (NJ GQS)[1]	6/03 EPA National Primary Drinking Water Standards (EPA MCL)[2]	2/05 NJ Drinking Water Standards (NJ MCL)[3]	Human Health Screening Level (EPA RSL)[4]	Screening Criteria[5]

µg/L - micrograms per liter
NL - not listed
MCL - Maximum Contaminant Level
TT - Treatment Technique
[AL] - Action Level
ca - value based on cancer effects
n - value based on noncancer effects
m - concentration may exceed ceiling limit
s - concentration may exceed saturation concentration
+ - New Jersey Interim Specific & Generic Groundwater Quality Criteria, July 7, 2008
(ignc) - Interim Generic Non-carcinogenic Criteria provided by NJDEP (100 ppb default for noncarcinogenic synthetic organic chemical)
- criteria is for a mixture of 2,4-dinitrotoluene and 2,6-dinitrotoluene
- criteria is for chlordane
- criteria is for chromium
* - an action level is not an MCL. It is a trigger point at which remedial action is to take place.
** - secondary standards
*** - based on 1,3-dichloropropene

Table 4-1
Proposed Analyses for Environemental Media by Area
Raritan Bay Slag Site
Old Bridge and Sayreville, New Jersey

Site Area	Media	Proposed Analyses [1]	Rationale
Area 1 Laurence Harbor Seawall	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. * 30% TOC, GS, pH	*Metals distibution in sediments *Organics in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and further refinement of the CSM *Organics in surface water related to potential releases from Areas 1, 4, and 9. *Chemical fate and and CSM development
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in soil *Characterize surface soils to provide data for the RI and risk assessments.
	Groundwater	*Total metals, mercury, Cr (VI) *100% VOCs, SVOCs, Pesticides, PCBs *TOC, DOC, TSS, pH, chloride, hardness, alkalinity	*Baseline groundwater quality for FS *Organics - potential organic sources in Area 1

Table 4-1
Proposed Analyses for Environemental Media by Area
Raritan Bay Slag Site
Old Bridge and Sayreville, New Jersey

Site Area	Media	Proposed Analyses [1]	Rationale
Area 2 Laurence Harbor Beach	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in sediments *Organics in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface Water	*Total and dissolved metals, mercury, Cr (VI) *30% VOCs, SVOCs, Pesticides, PCBs. *TOC, DOC, pH, hardness, chloride, alkalinity	*To support the RI, risk assessment, and further refinement of the CSM *Organics related to potential releases from Areas 1, 4, 9
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in soil *Organics in soil related to potential releases from Areas 1, 4, and 9. *TOC and pH - adjust soil screening criteria *GS - soil characteristics for FS.
Area 3 Laurence Harbor Playground	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *30% TOC, GS, pH	*Metals distibution in soil *Organics in soil related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust soil screening criteria for pH and TOC. *GS - soil characteristics for FS.
Area 4 Old Bridge Waterfront Park	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in soil *Organics - potential organic sources in Area 4 *TOC, GS, and pH - adjust soil screening criteria for pH and TOC. *GS - soil characteristics for FS.

Table 4-1
Proposed Analyses for Environemental Media by Area
Raritan Bay Slag Site
Old Bridge and Sayreville, New Jersey

Site Area	Media	Proposed Analyses [1]	Rationale
Area 5 Laurence Harbor Beach	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in sediments *Organics in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface water	*Total and dissolved metals, mercury, Cr(VI) *40% VOCs, SVOCs, Pesticides, PCBs *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and refinement of the conceptual site model *Organics related to potential releases from Areas 1, 4, 9
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *30% TOC, GS, pH	To characterize Area 5 surface soils and provide data for the RI and risk assessments.
Area 6 Laurence Harbor Beach	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *30% TOC, GS, pH	*Metals distibution in sediments *Organics in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and refinement of the conceptual site model *Organics related to potential releases from Areas 1, 4, 9
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in soil *Organics - potential releases from Areas 1,4, and 9 *TOC, GS, and pH - adjust soil screening criteria for pH and TOC. *GS - soil characteristics for FS.
Area 7 Cheesequake Creek Inlet	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in sediments. *Evaluate potential organics contamination in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.

Table 4-1
Proposed Analyses for Environemental Media by Area
Raritan Bay Slag Site
Old Bridge and Sayreville, New Jersey

Site Area	Media	Proposed Analyses [1]	Rationale
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and refinement of the conceptual site model *Organics related to potential releases from Areas 1, 4, 9
Area 8 Cheesequake Creek Inlet Western Jetty	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *30% TOC, GS, pH	*Metals distibution in sediments *Evaluate potential organics contamination in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *20% VOCs, SVOCs, Pesticides, PCBs. *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and refinement of the conceptual site model *Organics related to potential releases from Areas 1, 4, 9
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *30% TOC, GS, pH	To characterize Area 1 surface soils and provide data for the RI and risk assessments. *TOC, GS, and pH - adjust soil screening criteria for pH and TOC. *GS - soil characteristics for FS.

Area 10 Background	Sediment	*Total metals, mercury, Cr (VI) *VOCs, SVOCs, Pesticides, PCBs. *TOC, GS, pH	All analyses included to determine background concentrations
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *VOCs, SVOCs, Pesticides, PCBs *TOC, DOC, pH, chloride, hardness, alkalinity	All analyses included to determine background concentrations
	Soil	*Total metals, mercury, Cr (VI) *VOCs, SVOCs, Pesticides, PCBs. *TOC, GS, pH	All analyses included to determine background concentrations
	Groundwater	*Total and dissolved metals, mercury, Cr (VI) *VOCs, SVOCs, Pesticides, PCBs. *TOC, DOC, pH *TSS, chloride, hardness, alkalinity	All analyses included to determine background concentrations

Table 4-1
Proposed Analyses for Environemental Media by Area
Raritan Bay Slag Site
Old Bridge and Sayreville, New Jersey

Site Area	Media	Proposed Analyses [1]	Rationale
Area 11 Depositional Areas	Sediment	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in sediments. *Organic contamination in sediment related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust sediment screening criteria for pH and TOC. *GS - sediment characteristics for FS.
	Surface water	*Total and dissolved metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs *TOC, DOC, pH, chloride, hardness, alkalinity	*To support the RI, risk assessment, and refinement of the conceptual site model *Organics related to potential releases from Areas 1, 4, 9
	Soil	*Total metals, mercury, Cr (VI) *40% VOCs, SVOCs, Pesticides, PCBs. *30% TOC, GS, pH	*Metals distibution in soils *Organics in soils related to potential releases from Areas 1, 4, and 9. *TOC, GS, and pH - adjust soil screening criteria for pH and TOC. *GS - soil characteristics for FS.

1 - All aqueous samples will include field measurments for temperature, ph, DO, turbidity, Eh, and conductivity.
2- Groundwater sampling program for Area 9 will be determined after soil, sediment, and surface water samples are collected.

Cr (VI) - Hexavalent chromium
DO - Dissolved oxygen
DOC - Dissolved organic carbon
Eh- Oxidation/reduction potential
FS - Feasibility study
GS - Grain size distribution
PCBs - Polychlorinated biphenyls
RI - Remedial investigation
SVOCs - semivolatile organic compounds
TOC - Total organic carbon
TSS - Total suspended solids
VOC - volatile organic compound

2.3 Discussion: The detected concentrations of lead significantly exceed the Department's human health-based Soil Cleanup Criteria. Ample visual evidence of human use of the site was observed during the site investigation, including footprints, bike/ATV tracks, campsites and promiscuous dumping.

In addition, the site is situated adjacent to sensitive environmental receptors – the wetlands and open water of the Margarets Creek and Raritan Bay. The site is mapped in the Department's Geographic Information System as "Critical Emergent Wetland" and as foraging habitat for a State-threatened species: the Black-Crowned Night Heron. The proximity of the contaminated areas to wetlands and open water suggests the possibility that contamination may be or may have migrated to these receptors via overland flow in surface runoff or via groundwater.

Given the sample results and potential receptors/exposures, this information was reported to the Department's Environmental Hotline and was assigned case # 07-04-18-1110-28.

3. Recommendation. It is recommended that Green Acres not purchase this property. Old Bridge Township should be advised of the results of the site investigation and be urged to enter a Memorandum of Agreement with the Site Remediation & Waste Management Program to address the contamination. Green Acres may reconsider acquisition of the site upon receipt by the Township of a No Further Action determination by the Site Remediation & Waste Management Program.

NOTES

1. Base Map and proposed sewer layout from R3M Engineering, Inc. "Plan and Profile" drawings dated February 24, 2005.

2. All soil borings were performed using Geoprobe direct-push boring equipment.

3. Deep fill samples (>1' bgs) collected from soil borings SB-1A,B,C through SB-6A,B,C were laboratory analyzed for full TCL and TAL. The surficial soils at these locations were field screened for metals using X-ray fluorescence (XRF), with minimum 20% laboratory analysis for TAL metals and base-neutral semivolatile compounds.

4. Surficial soil samples B-1 (A, B, C) through B-7 (A, B , C) were field screened for metals using XRF, with minimum 20% laboratory analysis for TAL metals.

5. Surficial soil samples S-1 through S-3 were field screened for metals using XRF and laboratory analyzed for TAL metals.

6. Surficial soil samples S-1A through S-3A were field screened with an XRF analyzer.

7. Groundwater samples collected from monitoring wells MW-1, MW-2, and MW-3 were analyzed for TCL VO+10 and TAL metals.

4. Surficial soil samples B-1 (A, B, C) through B-7 (A, B, C) were field screened for metals using XRF, with minimum 20% laboratory analysis for TAL metals.

5. Surficial soil samples S-1 through S-3 were field screened for metals using XRF and laboratory analyzed for TAL metals.

6. Groundwater samples collected from monitoring wells MW-1, MW-2, and MW-3 were analyzed for TCL VO+10 and TAL metals.

7. Results shown exceed the NJDEP Residential Direct Contact Soil Cleanup Criteria (RDCSCC).

8. Laboratory results are shown in gold. XRF Results are shown in silver.

NOTES

1. Base Map and proposed sewer layout from R3M Engineering, Inc. "Plan and Profile" drawings dated February 24, 2005.

2. All soil borings were performed using Geoprobe direct-push boring equipment.

3. Deep fill samples (>1' bgs) collected from soil borings SB-1A,B,C through SB-6A,B,C were laboratory analyzed for full TCL and TAL. The surficial soils at these locations were field screened for metals using X-ray fluorescence (XRF), with minimum 20% laboratory analysis for TAL metals and base-neutral semivolatile compounds.

4. Surficial soil samples B-1 (A, B, C) through B-7 (A, B, C) were field screened for metals using XRF, with minimum 20% laboratory analysis for TAL metals.

5. Surficial soil samples S-1 through S-3 were field screened for metals using XRF and laboratory analyzed for TAL metals.

6. Groundwater samples collected from monitoring wells MW-1, MW-2, and MW-3 were analyzed for TCL VO-10 and TAL metals.

7. Groundwater results shown exceed the Groundwater Quality Standards (GWQS).

NOTES

1. Base Map and proposed sewer layout from R3M Engineering, Inc. "Soil Erosion and Sediment Control Plan" drawings dated March 16, 2007.
2. Topographic information is based upon aerial topography prepared by ADR Associates, Inc., dated April 4, 1994, provided by Old Bridge Township Municipal Utilities Authority and supplemented by CME Associates through September 13, 2004.
3. All elevations are based on NAVD 1988 U.S. Survey Foot as derived from aerial mapping provided by Old Bridge Township Municipal Utilities Authority.
4. Baseline stationing is measured along the alignment of proposed sanitary sewer.

Bioavailability

1 Definition of Bioavailability

Bioavailability is the extent to which a substance can be absorbed by a living organism and can cause an adverse physiological or toxicological response (Battelle and Exponent 2000). Bioavailability is particularly relevant for metals, which may exist in a variety of chemical and physical forms, not all of which are readily absorbed by the body when ingested. However, most oral reference doses (RfDs) and cancer slope factors (CSF) used in risk assessment are based on studies in which dose is reported as the amount of chemical ingested. Such studies make no assumptions concerning bioavailability. If the form of a chemical in the environment is different from the form relevant to toxicology or human epidemiological studies, these toxicity criteria may overestimate the risks (EPA 2005). In such cases, toxicity criteria (e.g., RfD, CSF) should be adjusted for the chemicals to reflect the reduced bioavailability of the chemical forms found at the site.

2 How Bioavailability is Expressed

Oral bioavailability of a substance can be expressed as either absolute bioavailability (ABA), or as relative bioavailability (RBA). ABA is the ratio of the amount of chemical absorbed to the amount ingested. RBA is the ratio of the amount of a test material, such as arsenic in soil, absorbed to the amount of an appropriate reference material, such as sodium arsenate. Sodium arsenate is considered an appropriate reference material for arsenic because it is a useful surrogate for the form(s) of arsenic on which oral toxicity criteria for arsenic are based. In the critical study, a large Taiwanese population was unknowingly exposed to high concentrations of arsenic dissolved in their drinking water. This arsenic appeared to be almost completely absorbed in the gastrointestinal tract. Sodium arsenate is soluble and available information suggests that it is also almost completely absorbed.

Typically both ABA and RBA are expressed as a percent. An ABA is useful for characterizing risk when a RfD and/or CSF are based on an absorbed dose. However, since most toxicity criteria are based on an administered rather than an absorbed dose, the ABA of a substance is generally not used in the human health risk assessment process. RBA is useful when the bioavailability of a chemical form relative to the form relevant to critical toxicological or epidemiological studies can be estimated.

Site-specific RBA values for contaminants of concern in site media may be used to adjust RfD and CSF as follows:

$$RfD_{adjusted} = RfD_{default} / RBA$$

$$CSF_{adjusted} = CSF_{default} * RBA$$

3 How Bioavailability is Determined

Historically the RBA of metals has been determined using *in vivo*, or animal-based studies. Typically i*n vivo* studies for arsenic have utilized young swine or primates, and have determined RBA coefficients through the comparison of the amount of arsenic ingested versus amount of arsenic excreted. *In vivo* studies are generally accepted as the best means of assessing bioavailability; however, they are expensive and can take many months to complete. Because of the expense and time requirements of the animal-based studies, researchers have developed an *in vitro*, or laboratory based method to determine RBA coefficients.

The *in vitro* method simulates the human stomach by reproducing stomach residence time, pH, temperature, agitation, and solid to liquid ratio. Prior to analysis the sample is sieved with a 250 micro sieve and the <250 micron sieved fraction of the sample is used in the analysis. The <250 micron fraction is analyzed as those particles are most likely to adhere to human skin and thus be ingested via hand to mouth processes. In general, the *in vitro* method consists of placing one gram of sample test material into a plastic bottle with 100 mL of an extraction fluid (0.4 M glycine, pH 1.5). Each plastic bottle is placed in a water bath maintained at 37°C, and samples are extracted by rotating the bottles end-over-end for 1 hour. After 1 hour, the bottles are removed, and placed upright to allow the soil to settle to the bottom. After settling, a 15-mL sample of supernatant fluid is removed directly from the extraction bottle into a disposable 20-cc syringe, and then filtered through a 0.45-um cellulose acetate disk filter to remove any suspended particulate matter. This filtered sample of extraction fluid is then analyzed to quantify the fraction of lead or arsenic in the sample which had dissolved.

Several studies, including one on arsenic impacted sediments from the Aberjona River (Brattin and Wahlquist 2002), have been conducted to assess the correlation between *in vivo* and *in vitro* bioavailability results. These studies suggest that the calculated *in vitro* Bioavailability (IVBA) coefficient is an appropriate screen to evaluate the relative *in vivo* bioavailability (Brattin and Wahlquist 2002). However, the correlation for arsenic is not strong enough to warrant using the *in vitro* method as a standalone means for the determination of a site-specific arsenic bioavailability coefficient. For these reasons EPA supports a weight-of-evidence approach which combines *in vitro* results and geochemical speciation data (EPA 2005).

Sample geochemical data are typically obtained via electronmicroprobe (EMP) analysis. The three geochemical properties most commonly considered in relation to metals bioavailability are mineral phase, matrix association, and particle size. A discussion of these geochemical properties is presented below:

- ***Mineral Phase:*** Refers to the chemical form, or species, in which the metal occurs in minerals composing site soil or sediment. Examples for arsenic include iron oxides; iron and zinc sulfates; iron sulfides; and arsenic bearing phosphates. In general, less soluble mineral phases are associated with low RBA values.

R2-0000249

- ***Matrix Association:*** Refers to the physical association of the metal bearing grains with other mineral phases or matrices that may limit contact of the metal bearing grain with gastrointestinal fluids. Metal bearing grains that are entirely free in the soil are referred to as "liberated," whereas grains that are bound together are referred to as "cemented". Particles that exist in a secondary phase coating are referred to as "rimming." Metal bearing grains that are fully encased or cemented are essentially isolated from gastrointestinal fluid, are not believed to be available for dissolution and adsorption, and thus are typically associated with lower RBA.

- ***Particle Size:*** Metals bearing particles occur in a large variety of sizes. Because dissolution of the particles in gastrointestinal fluid only occurs on a particle's surface, large particles are likely associated with lower RBA values than smaller ones, because the ratio of particle surface area to volume tends to decrease as size increases.

While all three of the above geochemical properties are considered in the development of a site-specific RBA coefficient, mineral phase shows the strongest correlation to bioavailability, and thus is considered more heavily.
