SSPL	State Street Parking Lot
SWMU	Solid waste management unit
TEA	Terminal electron acceptor
TRSR	(NJDEP) Technical Requirements for Site Remediation
USEPA	U.S. Environmental Protection Agency
VOC	Volatile organic compound

EXECUTIVE SUMMARY

This implementation work plan (IWP) for monitored natural attenuation (MNA) in groundwater has been prepared for the Former Chevron Perth Amboy Facility (Facility) in Perth Amboy, New Jersey. Although this facility currently operates as a petroleum products terminal, it has historically also functioned as a refinery and petroleum storage facility.

A corrective measures study (CMS) was conducted in 2008 to develop remedial measures to:

- Prevent exposure of humans to groundwater contaminants at concentrations above regulatory standards,
- Remediate contaminant concentrations in groundwater to below applicable regulatory standards, and
- Prevent or minimize migration of contaminant plumes for the potential contaminants of concern.

Significant portions of Facility source material for groundwater contamination have been removed, and the remaining areas are scheduled for treatment by the end of 2020.

The groundwater-specific cleanup goal for the MNA corrective measure component of the CMS is to reduce dissolved-phase benzene within the selected treatment areas to below 1 microgram per liter. Benzene will be the focus of this report because it is representative of other petroleum hydrocarbons and volatile organic carbons (VOC), and its successful reduction is coupled to the reduction of other VOC constituents to below groundwater quality standards. Benzene MNA is well established and is currently active in all three Yards of the Facility. This natural bioattenuation is occurring simultaneously to, and along-side of, other mass-reduction efforts at the Facility.

The purpose of this IWP is to assess currently available MNA data, summarize the status of benzene MNA, demonstrate MNA is reducing site benzene and other constituents as expected, and provide a Facility-wide monitoring plan for MNA parameters.

The focus of this IWP are the three Yards that make up the Facility: the Main Yard, Central Yard and East Yard. In addition to assessing currently-available MNA parameters, this IWP details procedures for making such assessments more detailed and accurate for future MNA reports. It is expected that the U.S. Environmental Protection Agency will issue a CA 550 determination (certification of remedy completion or construction completion) once MNA is demonstrated to be occurring in Facility groundwater.

1.0 INTRODUCTION

Parsons Environment and Infrastructure, Inc. (Parsons) has prepared this Implementation Work Plan (IWP) for the former Chevron Perth Amboy Facility (Facility) located at 1200 State Street, Perth Amboy, New Jersey (**Figure 1).** Monitored natural attenuation (MNA) was proposed as a corrective measure (CM) in the Corrective Measures Study (CMS) Final Report (Chevron 2008a), either as a standalone CM or in combination with other CMs, to achieve the remediation goals for organic contamination in groundwater. This IWP updates and expands on the design, approach and details of the MNA CM, which was approved in the 2013 Hazardous and Solid Waste Amendments (HSWA) Permit Renewal.

MNA is the reliance on natural processes to achieve cleanup criteria. These processes act without human intervention to reduce the mass, toxicity, mobility, volume, and/or concentration of contaminants in soil and/or groundwater. These in-situ processes can be either abiotic or biological and include: biodegradation, dispersion, dilution, sorption, volatilization, chemical or biological stabilization, transformation, or destruction of contaminants. Naturally occurring biological stabilization or destruction of contaminants (also known as intrinsic bioremediation) can be a dominant process in the fate and transport of contaminants. It occurs when naturally occurring microorganisms consume or otherwise degrade contaminants either aerobically or anaerobically, and ultimately transform the contaminants into harmless byproducts such as carbon dioxide and water. MNA requires monitoring procedures to ensure its effectiveness and that cleanup criteria are being met within a reasonable timeframe.

Significant mass reduction efforts have successfully removed material believed to be contributing to dissolved groundwater contamination at the Facility. Only a few areas remain, and these are actively being targeted for mass reduction. A preliminary evaluation of MNA at the Facility indicates that natural attenuation processes are also operating to reduce contaminants. This is expected, as MNA does not wait for bulk-mass removal to begin, but instead functions simultaneously in areas where conditions are conducive to biodegradation.

This IWP governs the tasks performed as part of the design, implementation, and monitoring of the MNA CM at the Facility. The purpose of this IWP is to assess the current status of MNA at this Facility as it pertains to benzene, as a representative of other hydrocarbon constituents. Specifically, the IWP summarizes available benzene-related MNA data and evaluates if MNA is functioning as expected to reduce site contamination, including benzene.

The following regulatory guidelines were considered during preparation of this IWP:

- Resource Conservation and Recovery Act (RCRA) Corrective Action Plan (CAP) Guidance (U.S. Environmental Protection Agency [USEPA] 1994).
- New Jersey Department of Environmental Protection's (NJDEP 2012b) Technical Requirements for Site Remediation (TRSR) (N.J.A.C. [1] 7:26E).

[1] N.J.A.C. – New Jersey Administrative Code

- Administrative Requirements for Site Remediation (N.J.A.C. 7:26C) (NJDEP 2012c).
- New Jersey Department of Environmental Protection's (NJDEP 2018) Ground Water Quality Standards (N.J.A.C. 7:9C).

1.1 Facility Location and Operational History

The Facility lies primarily in the industrial zone of Perth Amboy, New Jersey, occupying approximately 268 acres. It is currently divided into three yards referred to as the Central Yard, East Yard, and Main Yard (**Figure 2**).

Chevron purchased the Facility in 1946 from Barber Asphalt Company, which had owned and operated the Facility since 1911. The Facility operated as a full-scale petroleum refinery from 1946 to 1983, producing liquefied petroleum gas, gasoline, fuel oil, and asphalt. In 1983, Chevron reduced its operations to refining asphalt while also continuing petroleum storage operations. On July 26, 2012, Chevron completed the sale of the Facility to Buckeye Partners, L.P. (Buckeye). Buckeye currently manages and operates the Facility as a petroleum products terminal. A more detailed description of the Facility ownership and its historical operations can be found in the 2008 CMS (Chevron).

1.2 Purpose

This IWP was prepared to address the requirements of the CM implementation (CMI) program, as contained in the HSWA Permit Renewal. The initial 2008 CMS focused on implementing MNA to remediate areas with groundwater benzene concentrations below 100 micrograms per liter (µg/L), and above NJDEP Ground Water Quality Standards (GWQS) (**Table 1**). For locations with higher benzene concentrations (>100 µg/L), more active remedial activities have been, and continue to be, implemented. However, as these active remedial processes achieve their goals of reducing benzene concentrations to below 100 µg/L, MNA will become the primary CM as initially outlined in the 2008 CMS.

Benzene is representative of other petroleum hydrocarbons and volatile organic carbons, and as such will be the primary focus of this report. The successful reduction of benzene is associated with the reduction of other site constituents to below groundwater quality standards. As such, this 2018 IWP assesses available benzene MNA data to determine the status of volatile organic compound (VOC) MNA CMs at the Facility.

Within the Facility, MNA is being conducted within the following solid waste management units (SWMUs) and areas of concern (AOCs) (**Figure 3)**:

- SWMUs: 5, 6, 8, 10, 11B, 15, 16, 17, 18, 19, 20, 21, 22, 24, 26, 29, 34, 35, 39, 40, 41, 42, 43,
- AOCs: 5, 6A, 6B, 8, 9A, 9B, 14, 15, 16A, 16B, 16C, 18, 22, 23, 25, 33, 34, 36, 37, 39, 41, 44, 45, 46, 48, and 49

It should be noted that several areas on the Facility were identified in the 2008 CMS as having exceedances of multiple principal contaminants of concern (PCOCs). The 2008 CMS proposed CMs for each contaminated media based on the individual PCOCs.

Implementation of multiple CMs to address the exceedances of PCOCs in those areas may be necessary. MNA is proposed as the final CM for each area.

1.3 Implementation Work Plan Organization

To facilitate review, the remainder of the plan is organized into the following sections:

- **Section 2** describes the MNA CM objectives and applicable regulatory requirements.
- **Section 3** describes the current conceptual site model (CSM).
- **Section 4** summarizes the current MNA data from the Facility.
- **Section 5** describes the general technical approach for MNA technology.
- **Section 6** describes the field implementation approach and methods.
- **Section 7** describes the reports that will be submitted to regulatory agencies.
- **Section 8** describes the health and safety aspects of the MNA CM.
- **Section 9** describes the permits that are required from various regulatory agencies to continue implementing the MNA CM.
- **Section 10** describes the project management approach for the MNA CM.
- **Section 11** describes the wastes that will be generated during the continued implementation of the MNA CM and management of the waste.
- **Section 12** describes the tentative, continued implementation schedule of the MNA CM for the selected SWMUs and AOCs.
- **Section 13** contains references for documents cited in this report.

2.0 TREATMENT OBJECTIVE AND REGULATORY REQUIREMENT

The following CM objectives were proposed for groundwater in the 2008 CMS for the Facility:

- Prevent exposure of humans to groundwater contaminants at concentrations above regulatory standards,
- Remediate contaminant concentrations in groundwater to below applicable regulatory standards, and
- Prevent or minimize migration of PCOC plumes.

2.1 MNA Corrective Measure Objective

As described in the 2008 CMS, benzene has been determined to be representative of the VOCs for the Facility. As such, benzene will be discussed in this document as an analog for all petroleum hydrocarbon VOCs present in groundwater.

The media-specific cleanup goal for the MNA CM, as established in the CMS, is as follows: Reduce dissolved phase benzene concentrations from less than 100 µg/L in groundwater to below the N.J.A.C 7:9:C GWQS for Class-IIA aquifers (1 µg/L benzene).When all groundwater CMs at the Facility are complete, a Facility-wide classification exception area (CEA) will be established for groundwater with constituents of concern (COCs) exceeding GWQCs (NJDEP 2018).

3.0 CONCEPTUAL SITE MODEL

3.1 Topography

The topography at the Facility has predominantly been shaped by construction activities performed during site development, such as cut and fill grading. The northern, central, and eastern portions of the Facility are relatively flat. Berms (generally 6 to 8 feet high) have been constructed around each petroleum storage tank for spill containment. Sheet piles have been installed to stabilize the fill zones along stretches of the Facility adjacent to Arthur Kill to the east. The elevation of the ground surface at the Facility generally varies from 2 to 25 feet National Geodetic Vertical Datum (NGVD) of 1929 in the Main Yard, 2 to 27 feet NGVD in the East Yard, and 12 to 45 feet NGVD in the Central Yard (**Figure 1**).

3.2 Geology

The general stratigraphy of the Facility consists of six major units overlying the bedrock, including:

- Fill
- Organic clay and peat (Clay Horizon A)
- Glacial till and outwash (till)
- Three members of the Raritan Formation
    - Woodbridge Clay (Clay Horizon B)
    - Farrington Sand (Sand Horizon B)
    - Raritan Fire Clay (Clay Horizon C)

A more detailed description of these units is provided in Section 1.4.1 of the 2008 CMS.

The fill contains varying amounts of sands, silts and clay. In addition, the fill also contains intermittent lenses of flyash, catalyst beads and construction debris usually found in the Main Yard and East Yard of the Facility. A brief description of the fill and Clay Horizon A for the Facility is provided below.

- The thickness of the fill varies from 7 to 19 feet in the Central Yard. Beneath the fill is Clay Horizon A, which varies from 3 to 19 feet thick. Sporadic and discontinuous layers of till have been observed within Clay Horizon A.
- The thickness of the fill varies from 4 to 20 feet in the East Yard. Beneath the fill is Clay Horizon A, which varies from less than 1 to 14 feet thick. Clay Horizon A is absent at times, and the fill is observed overlying the till in the northern portion of East Yard.
- The fill varies from 3 to 15 feet thick in the Main Yard. Beneath the fill layer is a discontinuous Clay Horizon A ranging from 1 to 12 feet thick. The fill overlays till where Clay Horizon A is absent.

3.3 Hydrogeology

3.3.1 Shallow Groundwater

The shallow groundwater at the Facility is mainly observed in the unconfined fill, perched on Clay Horizon A and till. A semi-annual groundwater gauging program is currently in place to monitor groundwater levels at the Facility. **Figure 5** depicts the groundwater elevation contours (data collected on October 30, 2017) for shallow groundwater. The shallow groundwater flow direction is generally to the northeast in the Main Yard, to the northeast in the East Yard, and to the east to southeast in the Central Yard. The hydraulic gradients measured across the Main Yard, East Yard and Central Yard generally ranged from 0.001 to 0.05 foot per foot.

3.3.2 Deep Groundwater

Chevron is currently monitoring the hydrogeology beneath the fill and Clay Horizon A. Deep monitoring wells and piezometers are primarily screened in the till (i.e., first native water bearing zone [deep groundwater] beneath the fill and Clay Horizon A). **Figure 6** depicts the groundwater elevation contours (data collected on October 30, 2017) for deep groundwater. Overall, the groundwater flow direction follows regional projections, east-northeast toward the Woodbridge Creek and the Arthur Kill. The horizontal gradients measured in the Main Yard ranged from 0.0005 to 0.008 foot per foot and in the East Yard ranged from 0.006 to 0.01 foot per foot, and in the Central Yard is from 0.006 to 0.026 foot per foot

3.4 Nature and Extent of Contamination

The sources of organic contamination in soil and groundwater at the Facility are primarily related to tetraethyl lead burial areas, historical waste management practices, and operational and petroleum storage areas.

Currently, the primary origin of groundwater contamination is light nonaqueous phase liquid (LNAPL) and hydrocarbons sorbed to soil. Known areas of LNAPL and impacted soil mass are the target of ongoing CM implementation activity, as most recently reported in the First Quarter 2018 Progress Report for the Hazardous and Solid Waste Amendment Permit (Chevron 2018a).

3.4.1 LNAPL Impacts

LNAPL has been historically observed at 22 areas in the Facility. This LNAPL is weathered petroleum found at relatively shallow depths (less than 10 feet below ground surface [bgs]) and is relatively immobile in the subsurface. LNAPL is typically found within the more permeable lenses and layers that were placed during various periods of filling and are not continuous. Many of the lenses are located below the water table. The extent of LNAPL impacts have been delineated. The most recent (first quarter [1Q] 2018) data are presented on **Figure 7**.

Active LNAPL Recovery Measures (LRMs) are occurring in 11 LNAPL areas. Of the remaining 11 areas, seven are being monitored for LNAPL with no LRMs, and four have

pending requests for no further action (NFA). To date, at least 4,208 gallons of LNAPL have been recovered through LRMs. In general, remaining LNAPL is highly weathered, resulting in a viscous material with limited remaining soluble constituents (Chevron 2008a).

In the Main Yard, measurable LNAPL was detected in nine monitoring wells in the NF2, NF3, and AOC 8-NF6 LNAPL areas, and the SWMU 5/21/43 and AOC 15/23/41 areas during the 1Q 2018 gauging event. In the East Yard, measurable LNAPL was detected in seven monitoring wells in SWMU 42, AOC 31, and PAOC 15 during the 1Q 2018 gauging event. No measurable LNAPL was detected in the Central Yard during 1Q 2018. Post-CM implementation concentration trend monitoring will be conducted to ensure treatments are effective in reducing the remaining contaminant mass.

3.4.2 Soil Benzene Contamination

Results of historical investigations were used to evaluate the extent of soil benzene impacts above 13 milligrams per kilogram (mg/kg). COCs in soil are primarily found in the fill materials at varying depths near waste management areas or operational areas. The fill material is composed primarily of low permeability silts and clays with some discontinuous lenses of sand. Across most of these areas, the fill material is underlain by a naturally-occurring layer of low permeability clay (Clay Horizon A) or a glacial till composed of silts and clay with some sand lenses (Chevron 2008a). Based on these results, the depth of benzene contamination exceeding 13 mg/kg generally ranges from 1.5 to 14.5 feet bgs in the Main Yard, 1.5 to 12 feet bgs in the East Yard, and 1 to 16 feet bgs in the Central Yard.

The highest historical concentrations of benzene in soil in the Main Yard were clustered in three areas in AOCs 23/41/SWMU 18, AOC 15/SWMUs 16/40, and AOC 8/NF 6. In the East Yard, the highest benzene in soil concentrations are clustered in four areas: AOC 31, AOC 37, AOC 14/SWMU 26, and SWMU 8. In the Central Yard, benzene impacted soil was detected in AOC 22 and AOC 36 near the former Shops Building and ladder track.

3.5 Potential Receptors

Potential receptors of benzene-impacted groundwater from the Facility are discussed in the sections below. As stated above, benzene will be the focus of this discussion as it is an analog for all petroleum hydrocarbons and VOCs at the facility.

3.5.1 Groundwater

In New Jersey, Class II groundwater is considered suitable for the provision of potable water with conventional water supply treatment. NJDEP classified groundwater in the Perth Amboy area as Class IIA, a potable water supply. However, groundwater quality in the uppermost water-bearing unit is degraded by various industrial activities and stormwater runoff from streets in this urban area. Near the Facility, the Farrington Aquifer outcrops along Woodbridge Creek. Historical pumping of the Farrington Aquifer caused salt water intrusion as the saline waters of Woodbridge Creek were drawn into the recharge area of the Farrington Aquifer. As documented in N.J.A.C. 7:9, Subchapter 6,

which covers GWQS, the Farrington Aquifer along the banks of Woodbridge Creek at and near the Facility is designated as Class IIIB groundwater, which is not suitable for conversion to potable uses. Groundwater is not used as a source of water supply within at least two miles of the Facility, because historical pumping from the Farrington Sand has resulted in nearby salt water encroachment.

The northern portion of Main Yard consists of tidal salt marsh wetlands (also known as North Field Basin [NFB] Wetlands). The surface water bodies, including Arthur Kill and Woodbridge Creek, are located along the northern and eastern property boundaries. Tidally influenced groundwater level fluctuations and salt water intrusion into the shallow water-bearing zone have been observed and documented in the areas near Woodbridge Creek. Data from wells in the NFB area have shown a tidally related groundwater elevation fluctuation of up to 1.5 feet. In contrast, the extent of tidal influence has not been fully clarified for monitoring wells in the East Yard Basin area. This potential tidal influence in the East Yard may be subsequently affected by bulkheads that have been placed along the Arthur Kill (Chevron 2008a).

3.5.2 Human Health

Several structures within the Facility are occupied. A vapor intrusion evaluation was conducted for the on-site structures, and it was concluded that the vapor intrusion exposure pathway does not pose a significant risk to potential receptors at the on-site structures (Chevron 2008a; Chevron 2016).

4.0 CURRENT STATE OF MONITORED NATURAL ATTENUATION

MNA is the reliance on natural biological and non-biological processes to achieve groundwater cleanup within a reasonable timeframe. These processes include biodegradation, dispersion, dilution, adsorption, volatilization, and chemical and biological stabilization. The goal of MNA is to reduce the mass, volume, mobility, toxicity, and/or concentration of groundwater contaminants. Naturally occurring stabilization or destruction of contaminants can be a dominant process governing the fate and transport of contaminants. Biological natural attenuation occurs when indigenous microorganisms degrade (consume) contaminants either aerobically (in the presence of oxygen) or anaerobically (in the absence of oxygen). Biodegradation, also called bioattenuation, can result in partial breakdown daughter products. Contaminants can also be fully mineralized to carbon dioxide.

The three, typically-accepted lines of evidence for assessing the efficiency of natural attenuation are:

1. Plume stabilization and/or loss of contaminant mass over time
2. Groundwater chemistry data showing that geochemical conditions are suitable for natural attenuation and the rate at which natural attenuation processes are active
3. Data demonstrating the occurrence of a natural attenuation process, typically used to demonstrate that biodegradation is occurring (USEPA 1999). These data can take many forms, including indirect geochemical data or direct biological assessments. Indirect biogeochemical data that are used to monitor bioattenuation can include evidence of depletion of electron acceptors and donors, increased metabolic byproduct concentrations, decreased parent compound concentrations, and increased daughter compound concentrations (Wiedemeier, et al. 1996; Wiedemeier, et al. 1999).

MNA does not wait for source removal to be completed, but instead functions simultaneously in areas where conditions allow.

MNA was evaluated for effectiveness, implementability, and cost in the 2008 Corrective Measures Study (Chevron). This evaluation determined that:

1. **Effectiveness** – The effectiveness of MNA depends on site conditions such as remaining contaminant mass, pH, temperature, microbial activity, and oxidation reduction potential (ORP). Data collected from the Facility prior to the 2008 CMS indicated that MNA would be effective for organic contaminants within a reasonable timeframe for the plume area outside source areas of contamination.
2. **Implementability** – Implementation of MNA as a CM entails a comprehensive groundwater monitoring program. A monitoring well network already exists at the Site and is being periodically monitored for MNA parameters. Therefore, MNA is easy to implement and monitor at the Facility.

3. **Cost** – The costs to implement and maintain an MNA monitoring program are low to moderate, depending on the number of wells sampled, the frequency of sampling, and the duration of sampling. MNA was being proposed as a follow-up to other more aggressive CMs and in areas of the Site with groundwater exceedances outside the remaining areas of contamination.

4.1 Benzene Plume Stability and Concentration Trends

As stated above, the first line of evidence for assessing the efficiency of natural attenuation is to monitor plume stabilization and/or loss of contaminant mass over time. The most complete historical reference available to facilitate this comparison is data from the time of the 2008 CMS.

At this Facility, the goal of the MNA CM is to reduce dissolved phase benzene concentrations in groundwater within the selected treatment areas to below 1 µg/L. This goal takes into account that benzene is acting as a representative of petroleum hydrocarbons and VOCs, and as such, benzene reduction will parallel the reduction of other constituents to groundwater quality standards.

4.1.1 *Historic Distribution of Benzene in Groundwater*

Multiple comingled benzene plumes were identified in each of the three Yards in the 2008 CMS (**Figure 8**). The plumes were generally associated with a known or suspected mass of benzene, either in soil or from LNAPL. The highest concentrations of benzene were generally found near the soil or LNAPL source, with decreasing concentrations extending downgradient (Chevron 2008a). Historic benzene data is presented in **Appendix A**.

Since 2013, the implementation of CMs in all three Yards has effectively reduced both soil and LNAPL sources in several areas, as discussed in detail below. Post-implementation dissolved benzene concentrations indicate that mass removal is complete in some areas, and dissolved benzene concentrations have decreased accordingly (**Figure 9**). When the 2008 footprint is compared to current data, it is apparent that the total amount of benzene present at the Facility has been significantly reduced (**Figure 10**). It should be noted that the contemporary data presented in **Figures 9** and **10** are the highest concentrations reported during the 2017Q2 to 2018Q1 period. As such, the resulting maps represent the most conservative interpretation of current plume conditions.

Areas with concentrations of benzene below 100 µg/L but above the GWQS will continue to be remediated through MNA. The total footprint of dissolved benzene between 100 µg/L and GWQS of 1 µg/L has increased from 2008 until 2018. Several plumes that were not identified at the time of the 2008 CMS have now been identified and are represented on **Figures 9** and **10**. Additionally, the reduction of elevated benzene concentrations from above 100 µg/L in 2008 to between 100 and 1 µg/L in 2017-2018 is included in the apparent increased extent of area requiring MNA.

Once source removal/treatment is completed, the decrease in areas of high concentrations will result in an overall increase in the footprint of low concentrations (1 to 100 µg/L) of benzene. Over time, however, the footprint of these low concentrations will subsequently decrease. This is because biodegradation of contaminants, such as hydrocarbons, occurs primarily in the lower-concentration zones of a plume.

There are multiple reasons for bioattenuation to be more active in zones peripheral to a plume core. First, more microbes are adapted to survive in, and then degrade, lower concentrations of a hydrocarbon than higher concentrations. In addition, areas of lower hydrocarbon concentration are often associated with less-reduced geochemical conditions, as seen at the Facility and discussed above. As such, the actual rate of biodegradation is commonly most rapid in areas of lower hydrocarbon concentration. Although the below-proposed use of in-situ microcosms would confirm this, all signs suggest that this fingerprint of microbial MNA is occurring at this Facility. Therefore, it is anticipated that MNA is a process that will continue to reduce the footprint of both the higher and lower benzene concentrations at the Facility.

4.1.2 Historical Decreases in Contaminant Concentrations Over Time

Dissolved benzene concentrations in Facility groundwater exceeding 100 µg/L generally extend from areas of petroleum hydrocarbon impacted soil or LNAPL. Once this zone has been treated through active remediation, concentrations of benzene in groundwater can follow the MNA patterns discussed above.

Mass removal continues at the Facility and is scheduled to be completed in 2020. Because CM implementation is in progress and will be continuing for an additional two years, post-remediation groundwater trends cannot be developed at this time. As CM implementation progresses, construction completion reports will be submitted detailing the remediation completed and the post-remediation groundwater trends. Once all CM implementation is complete, trends for evaluation of MNA will be included in the MNA annual reports.

As stated above, **Figures 9** and **10** represent the most conservative interpretation of current plume conditions, since they use the highest concentrations reported during the 2017Q2 to 2018Q1 period.

Footprint Size of Dissolved Benzene Concentrations (square feet)

CMI Area: 2008 (>100 µg/L)	CMI Area: 2017-2018 (>100 µg/L)	Reduction in CMI Area (>100 µg/L)
289,744	215,042	74,702

In the last 10 years, over 74,700 square feet of the Facility have seen a reduction in benzene concentration from above the CMI action level (100 µg/L) to below this target concentration. Active CM activities will continue in areas where concentrations remain above 100 µg/L.

Central Yard

The Central Yard of the Facility has shown a complete reduction of benzene concentrations above 100 µg/L, in comparison to 2008 (**Figure 10** and **Appendix A**). Several mass removal events have contributed to the reduction in total contaminant mass in the Central Yard. Details of each of these remedial actions are, or will be, included in the construction completion reports for the associated AOC or SWMU.

Figure 10 also illustrates that the footprint of concentrations below 100 µg/L has been substantially reduced in the Central Yard benzene plumes. Small areas remain where MNA will continue to reduce benzene concentrations. Finally, **Figure 10** demonstrates that the footprint of concentrations above 10 µg/L has been substantially reduced in the benzene plumes. Remaining benzene is found in small areas where concentrations do not exceed 10 µg/L.

In summary, the footprint of impacted groundwater is significantly reduced in the northwest plume. As such, the benzene plume in the Central Yard of this Facility is not only stable but shrinking in both benzene mass and footprint size.

It should be noted that:

- In the northwestern plume, an excavation to remove LNAPL and hydrocarbon impacted soil from AOC 25 occurred in September 2016. Concentrations prior to excavation were consistently above CMI action limits and have consistently been less than 10 µg/L since the excavation.
- In the southern plume, near AOC 36 and SWMU 34, enhanced in-situ bioremediation (EISB) was conducted until April 3, 2014. Benzene concentrations in the area have been reduced from greater than 100 µg/L measured in MW-102 in 2008 to less than 100 µg/L in all area wells in 2017-2018.
- In the State Street Parking Lot (SSPL), in SWMUs 11a and 11b, benzene impacted groundwater was discovered after the 2008 CMS. Data from well TP2-018 indicate that benzene concentrations in this area exceeded 1,000 µg/L in 2009. A remedial excavation occurred in SWMU 11a in September 2015, and ISCO soil mixing was completed in SWMU 11b in February 2017. Data from post-CM implementation monitoring wells MW-438, MW-431R and MW-509 indicate that benzene concentrations have been reduced to less than 100 µg/L in the SSPL.

Main Yard

In 2008, the Main Yard was characterized by several distinct areas where benzene concentrations were elevated (**Figures 8** and **10**). The “Main Yard Plume” includes the large commingled plume, which extends from SWMU 5/21/43 in the northwest to AOC 15/8 in the southeast. Other benzene plumes within the Main Yard include those near AOCs 5 and 44 (extending to the northwestern corner of the Facility), AOC 33 near the eastern Facility boundary, and AOC 50 at the Truck Loading Rack east of the Main Yard.

A variety of CM implementation actions have been completed in the Main Yard to date, and additional CM implementations are scheduled to continue into the year 2020. Some

benzene impacted soil has been placed in the CAMU either due to benzene-impacted soil being collocated with lead or benzo(a)pyrene impacted soil, or in lieu of ISCO injections when the benzene source zone was identified as a limited volume of soil, and thus excavation was deemed more efficient than ISCO injections. The following CM implementation actions have been completed in the Main Yard:

- In the northwest corner of the Facility, near AOC 5 and SWMUs 27/29/30/38/39, soil was excavated for ISS/ESS in 2015 and 2016. An area of elevated benzene concentrations (>100 µg/L) in groundwater remains near MW-404R and MW-406. This area was not identified in 2008.
- In AOC 9A, an excavation to address benzene in soil was completed in December 2017. The upgradient extent of this plume has been defined as extending farther to the south than in 2008, with the installation of MW-376 and MW-379. Concentrations of benzene in the downgradient extent of the plume have decreased from >100 µg/L in MW-266 in 2008 to less than 10 µg/L in 2017-2018.
- In SWMU 19 an excavation was completed in November 2016 to address lead and benzo(a)pyrene. In 2008, benzene concentrations in SWMU 19 groundwater were above the GWQS of 1 µg/L; however, concentrations in this area have decreased, and an NFA justification for SWMU 19 benzene in groundwater was approved by NJDEP on December 16, 2016.
- In AOC 44, ISCO injections were completed in 2014. The downgradient edges of this plume have reduced since 2008. However, an area of high benzene concentrations was detected upgradient of the 2008 plume boundary (**Figure 10**). An additional round of ISCO injections is planned to address the remainder of the benzene impacted soil and groundwater in this area.
- In AOC 50, a remedial excavation was completed to address lead and benzene in soil in September 2017. Concentrations of benzene remain elevated in MW-521, and post-remediation trends will continue to be monitored in this area.
- In the eastern Main Yard Plume area, in SWMUs 6/7/16/40, in January 2016 excavation was completed to address benzo(a)pyrene and lead in soil. Benzene in groundwater concentrations have been reduced from >1,000 µg/L in MW-125 and MW-243, to <1000 µg/L in MW-125 and <10 µg/L in MW-243R. Additional ISCO CM implementation actions are planned in this area.
- In SWMU 20, an ESS excavation to address lead in soil was completed in August 2016. Benzene in groundwater concentrations were reduced from >100 µg/L in MW-266 in 2008 to <10 µg/L in 2017-2018.

Details of each of these remedial actions are, or will be, included in the Construction Completion Reports for the appropriate AOC or SWMU, and will be submitted under a separate cover. Currently, only three of these areas have groundwater concentrations over 1,000 µg/L, and nine areas have benzene concentrations above the CMI action limit of 100 µg/L (**Appendix B**, **Figures 9** and **10**). These areas are scheduled for additional CMI activities in 2019 and 2020. Additionally, the area near SWMU 43 and to the west near AOC 33 have shown reductions of benzene concentrations to below GWQS of 1 µg/L

(**Figure 10**). A comparison of benzene concentrations and locations between 2008 and 2018 demonstrates that the plumes in this Yard are stable or shrinking into themselves.

East Yard

In 2008, the East Yard was characterized by several plumes extending downgradient from six source areas. The following CMI activities have been conducted since 2008:

- SWMU 8, in the northeastern corner of the East Yard, received two rounds of ISCO injections in 2013. ESS for lead was completed in 2016. In 2008, benzene concentrations in MW-132 were greater than 100 µg/L. Concentrations in MW-132R had been reduced to less than 10 µg/L in 2017-2018, and the SWMU 8 benzene plume extent is reduced as compared to 2008.
- Two rounds of ISCO injections were completed in SWMU 10 in 2015, and ISS/ESS for lead was completed in June 2016. Concentrations of benzene in MW-131 were greater than 100 µg/L in 2008 and below 100 µg/L in MW-131R in 2017-2018.
- ESS addressed lead concentrations in soil in SWMU 42. Benzene concentrations in the ESS CM area (MW-227) were greater than 100 µg/L in 2008 and have been reduced to less than 10 µg/L in 2018.
- Soils with elevated concentrations of benzene in AOCs 14 and 26 were excavated in November and December 2017. Dissolved benzene concentrations in this area have decreased to less than 10 µg/L since 2008.
- AOC 31 was the site of electrical resistance heating system operations until 2014. ISCO injections in this area began in 2017 and are ongoing in 2018. The footprint of concentrations exceeding 100 µg/L has been reduced, and CM activities will continue in this area. Additionally, the downgradient portion of the plume has decreased to less that the GWQS of 1 µg/L along the northern property boundary.
- AOC 38 and AOC 39 were not identified as having elevated benzene in groundwater in 2008. However, these areas were treated for benzene in soil in October 2017 and January 2018, respectively. Benzene concentrations in MW-400 and MW-401 will be monitored to determine whether additional CM actions are warranted.
- AOC 46 was treated via ISCO injection in November and December 2015, concentrations of benzene in this area are less than 100 µg/L in 2017-2018.

Details of each of these remedial actions are or will be included in the construction completion reports for the appropriate AOC or SWMU and will be submitted under a separate cover. In 2008, the AOC 31 portion of the East Yard contained two areas of very high (above 1000 µg/L) benzene concentrations (**Appendix B**, **Figures 8** and **10**). By 2018, the areas identified in 2008 have been reduced in size (**Figure 10**). ISCO injections are in progress in AOC 31 and will continue until CMI action levels are reached.

As the above CM remedies were being implemented, areas of lower concentrations were simultaneously being reduced through MNA processes. As a result, when compared to 2008, current plume footprints indicate that many areas of the plumes are stable or shrinking.

4.2 MNA Parameters: Overview

As stated above, in addition to monitoring plume stabilization and/or loss of contaminant mass over time, equally important lines of evidence for assessing the efficiency of natural attenuation involve MNA geochemical parameters. To evaluate the potential for MNA, MNA-related geochemical data from approximately 320 monitoring wells located in the Main Yard, East Yard and Central Yard of the Site were analyzed for some combination of groundwater geochemical (MNA) parameters between 2014 and 2018 (**Appendices A** and **B**). These data were analyzed to evaluate the potential for MNA to effectively reduce organic contamination in the groundwater, and to determine if MNA appears to be occurring.

MNA parameters such as total alkalinity, pH, ORP, sulfate, sulfide, dissolved (ferrous) iron, total iron, dissolved oxygen (DO), and nitrates provide useful, if indirect, information on the biodegradation potential of the contaminated media. This process has been summarized in many publications including, but not limited to: Talley (2006), Wiedemeier et al. (1999), and Young and Mulligan (2003).

There are several field-tested MNA parameters. For example, microbes have minimum and maximum tolerances and optimum levels for both temperature and pH. The ORP value is a measure of electrical current in groundwater, which reflects how oxygenated or reduced an environment is. The ORP value will provide information about which form of microbial metabolism will likely dominate the area being tested.

An increase in alkalinity, which generally reflects the amount of bicarbonate in groundwater, is an indication of the biodegradation of organics. As such, alkalinity can provide indirect insights into whether site contaminants are being fully mineralized, and thus can allow for qualitative comparisons between locations or timepoints.

The DO value and groundwater concentrations of nitrate, total iron, ferrous iron, sulfate, sulfide, and methane are metrics used to indirectly determine if biological degradation is occurring and under what metabolic process. Every microbe contains a chemical that is referred to as the terminal electron acceptor (TEA). As this TEA scavenges and binds up free electrons, it is transformed from an oxidized form into a reduced form. Depending on the type of TEA used, different amounts of energy are ultimately produced for the microbe. However, microbes will metabolize (consume) organic material (including hydrocarbons) in a way that will allow for the greatest resulting energy generation to occur under site conditions. As such, there is a sequential preference for the form of metabolism to be used.

If oxygen is present, aerobic bacteria will conduct aerobic metabolism, generating the most energy (per unit of organic material) of the metabolic processes. If oxygen is not present, or has been consumed, then the microbial population will transition to utilize other

electron acceptors, beginning with nitrate. Once nitrate concentrations become depleted, iron-reducing bacteria will dominate the population. As ferric iron concentrations become low, this community will transition to one dominated by sulfate-reducing bacteria, if sulfate is present. If sulfate becomes depleted, the microbial community will transition to the lowest-energy-producing metabolism of methanogenesis.

Summary of the Sequential Utilization of TEAs in an Environment

Metabolic Degradation Process Name	TEA Utilized	Product of the Reduction of the TEA	Type of Microbe Performing This Metabolism
Aerobic	Oxygen	Water	Aerobes
Nitrate Reduction	Nitrate	Nitrite	Nitrate Reducers
Iron Reduction	Ferric Iron [Fe (III)]	Ferrous Iron [Fe (II)]	Iron Reducers
Sulfate Reduction	Sulfate	Sulfide	Sulfate Reducing Bacteria
Methanogenesis	Carbon Dioxide	Methane	Methanogens

Because of this sequential utilization of TEAs, the resulting groundwater geochemistry can develop a “fingerprint” of biological natural attenuation. Assuming that nutrients (including appropriate TEAs) are not being replenished in the environment fast enough to overcome utilization rates, the above-described process of transitioning from one dominant metabolism to another will occur. Eventually, the environment will reach an equilibrium in which higher concentrations of organic matter will corelate with more reduced environmental conditions. Thus, in the case of a hydrocarbon plume (for example), the core of the plume will be more reduced relative to the periphery of the plume.

The most impacted core of a hydrocarbon plume may be under the influence of sulfate-reducing to methanogenic conditions. Moving away from this core toward the periphery where hydrocarbon concentrations are lower, conditions often become dominated by iron-reducing conditions, nitrate-reducing conditions, and if oxygen is present at the plume periphery aerobic conditions. This classic fingerprint is a hallmark of biological contaminant degradation.

It is worth noting that, although an overall microbial community can be dominated by a metabolic process, multiple TEA processes can occur simultaneously in a location. Additionally, micro-environments as well as stratified TEA processes with depth can exist. Finally, TEA processes can be dynamic. As such, this classic fingerprint can sometimes be less clear in some locations in comparison to others.

It is important to remember that these TEA processes are at work on both naturally-occurring organic matter (such as decomposing plant material) and organic contaminants (such as hydrocarbons). This underscores the importance of trying to find upgradient or background groundwater to compare against the geochemical parameters found within

the core and periphery of a contaminant plume. However, this ideal situation may not be available at all locations, and less-ideal monitoring wells may have to be accepted as a representation of background conditions. Additionally, the microbial degradation of non-contaminant material possibly found in the subsurface of a site is important to remember because byproducts such as methane can be generated from this innocuous material. Methane is a gas, and as such, it travels easily from one location to another via preferential pathways. These include subsurface features and along monitoring well casings that may have perforated a methanogenic pocket. Thus, methane generated in one location can easily travel, and be detected, in a very different location. Together, these variables underscore the importance of looking at multiple lines of evidence when evaluating MNA.

One final quality of MNA that makes it particularly beneficial is that it will occur as long as the above-described environmental conditions will allow it to. Thus, MNA is often occurring in less impacted regions of a location that is also undergoing bulk source material removal.

4.3 MNA Parameters: Data Assessment

For organizational purposes, this Facility is subdivided into three main areas: the Central Yard, Main Yard, and East Yard. The varying historical uses, geography, and geology of each of these three subdivisions makes it appropriate to look at MNA within each subdivision individually.

All data discussed were reported for 2014 through 2017, unless otherwise noted. Regarding benzene concentrations, the discussion below follows the trend established by Facility maps: areas of higher benzene concentration will be defined as those exceeding 100 µg/L, and areas of lower concentration will be defined as those having benzene concentrations ranging from 1 through 100 µg/L. This is based on criteria used on plume maps for historical quarterly and other reports. However, any exceptions will be noted. In addition to considering historical benzene concentration data, wells chosen for discussion also needed to have enough recent MNA geochemistry data for a proper assessment to occur.

For the purposes of this report, monitoring wells described as “background” are those where benzene concentrations have typically been detected at concentrations below 1 µg/L and have available and recent MNA data for a proper assessment to be made. At a Facility such as this, it is common to have no available monitoring wells that are non-detect for COCs. It is also not unusual to have limited upgradient wells available for assessment, due to property lines and groundwater flow patterns complicated by above-ground and subsurface structures. In these situations, monitoring wells that consistently have low COC concentrations can serve as baseline wells, providing the best available view of conditions away from the bulk of the plume.

For all three Facility yards, groundwater benzene and other VOC data are provided in **Appendix A**. Groundwater geochemistry, including the MNA parameter data discussed below, is provided in **Appendix B**.

Finally, when a monitoring well is introduced in the discussion below, its associated (or nearby) AOC or SWMU will be listed in parenthesis. This is to help facilitate comparisons in other Facility documents.

4.3.1 Central Yard

The Central Yard is the most inland of the three yards, having no waterfront access. Background conditions in the Central Yard are dominated by nitrate reducing to iron-reducing conditions, as demonstrated in MW-416 (Former PAOC 82) and MW-417 (Former PAOC 82) (**Appendix B**). In these wells, nitrate was continuously below 40 µg/L, indicating that this nutrient and TEA were consistently depleted**.** However, ferrous iron concentrations were robust, ranging from 108,000 and 1,120,000 µg/L in 2016 and 2017. Sulfate concentrations were also elevated in these two monitoring wells, ranging from 189,00 to 287,000 µg/L in 2016 and 2017. Available ORP and DO values also remained elevated in these two background wells. Together, these data suggest that these two wells were strongly under the influence of iron-reducing conditions.

Concentrations of benzene in all Central Yard monitoring wells were less than 100 µg/L in 2017 and 1Q 2018 (**Appendix A**). However, several monitoring wells had lower benzene concentrations (**Figure 9**). Monitoring wells MW-167, MW-168, and MW-169R are near AOC 36, in the southern tip of the Central Yard, downgradient of the southern Central Yard plume. MW-169R has demonstrated benzene concentrations below the GWQS for several years. MW-167 and MW-168 have been non-detect for benzene since at least 2010. When compared with background wells, nitrate concentrations are depleted in MW-167 and MW-169R, nitrate concentrations were continuously elevated in MW-168. Ferrous iron concentrations were reduced compared to those from background wells, ranging from depleted to 16,700 µg/L in 2016 to 2017. Sulfate levels were also generally reduced compared to background, ranging from 6,300 to 79,600 µg/L in 2016 to 2017. This suggests that these monitoring wells are under more reduced conditions than background wells, likely under the influence of a mix of iron-reducing to possibly light sulfate-reducing conditions. Available ORP values support that these periphery wells are more reduced than background Central Yard wells.

These MNA parameters are similar to those detected in MW-216 and MW-217, both of which are in the most concentrated area of that particular benzene plume in AOC 36. Benzene concentrations in these two monitoring wells have ranged from 29 to 46 µg/L over the past three years (**Appendix B**). This suggests that active bioattenuation of benzene has been working inwards from the periphery of this plume and has become active in the areas of highest benzene concentrations.

The second major area of interest within the Central Yard is northwest of the area described above. Only one monitoring well, MW-360 (near Former PAOC 74), has available data for assessing MNA in the periphery of this area of low benzene concentrations (**Appendix B**). As with the above-described periphery monitoring wells, nitrate is generally depleted. Sulfate concentrations were reported to be between 38,700 and 54,000 µg/L, which are consistently higher than concentrations found even in background wells. Ferrous iron was substantially reduced compared to background

concentrations. In fact, ferrous iron concentrations were mostly depleted (except for one data point in 2017). This suggests that this region of the Central Yard is under primarily nitrate-reducing conditions, following the expected pattern for hydrocarbon MNA, where the area around the contaminant is more reduced than background areas. The cause of the consistently-elevated sulfate concentrations in MW-360 is unclear.

It should be noted that in the 2008 CMS, it was reported that Chevron had already evaluated and implemented MNA as a remedial approach for AOC 36, a chlorinated plume in the southern portion of the Central Yard that emanated from the southwestern portion of the former Shops building. MNA parameters analyzed during this evaluation indicated that daughter products of chlorinated solvents trichloroethane and perchloroethylene were detected in the area groundwater indicating that anaerobic biological reactions were occurring. Details regarding AOC 36, the bioremediation of chlorinated constituents, past EISB efforts, current site conditions, and upcoming EISB efforts are detailed in an AOC 36-specific report (Chevron 2018b).

4.3.2 Main Yard

The Main Yard is like the Central Yard in that it contains areas of both low and high concentrations of benzene (defined above). In contrast, however, a greater portion of the Main Yard is impacted with benzene than is the Central Yard. The northern end of the Main Yard is also bounded by the Woodbridge Creek. Multiple ISCO CM actions have been completed within the Main Yard, targeting some of the areas of higher benzene impact which have acted as source material for groundwater impacts. ISCO processes are chemicals injected or mixed to chemically oxidize target contaminants, such as benzene. The indigenous microbiology is also altered during this process, by being subjected to sudden and intense oxidizing conditions (Fedrizzi et al. 2017; Polli et al. 2018; Sutton et al. 2015). For the purposes of this MNA discussion, monitoring wells chosen to represent various biogeochemical states will deliberately be outside of areas strongly impacted by the various ISCO CM activities within the Main Yard.

Additionally, areas of benzene impacted soil that were collocated with elevated concentrations of lead and benzo(a)pyrene in SWMU 18/AOC 23/AOC 41 have been removed and placed in the CAMU as part of the ESS CM implementation. Dissolved phase benzene concentrations in this area have been reduced from greater than 1,000 µg/L in 2008 to between 1 and 10 µg/L in 2017-2018.

Similar to the Central Yard, background wells in the Main Yard are dominated by nitrate-reducing processes, as represented by MW-154 (MY4), MW-314 (AOC 33), and MW-373 (Former PAOC 84) (**Appendix B**). Nitrate is depleted in all three monitoring wells. Ferrous iron concentrations are three times higher in MW-373 than in MW-154, ranging from 13,500 to 22,000 µg/L. Ferrous iron is even higher in MW-314, ranging from 39,200 to 49,500 µg/L. Sulfate concentrations ranged from approximately 10,000 to 30,000 µg/L in MW-154 and MW-373, with sulfate averaging approximately 2,500 µg/L in MW-373. These data suggest that MW-154 is dominated by strong nitrate-reducing conditions to mild iron-reducing conditions. MW-373 is slightly more reduced, with MNA data trending toward slightly more influence by iron-reducing processes. MW-314 is the most reduced of the

three background wells, clearly under the influence of iron-reducing conditions. Available ORP values support these findings.

Monitoring wells located in areas of low benzene concentration are more reduced than those located outside impacted areas. Represented by MW-0060 (SWMU 43, near the surge pond), MW-118 (AOC 8-NF6), MW-125 (AOC 8-NF6), and MW-395 (PAOC 46), nitrate is depleted in this zone. Detected ferrous iron concentrations are highly variable, ranging from 678 to 33,500 µg/L in 2016 to 2017 (**Appendix B**). These values are generally lower than, or similar to, concentrations detected in background wells. Sulfate concentrations ranged from being often depleted to 189,000 µg/L in 2016 to 2017. Monitoring well MW-118 consistently had sulfate concentrations that were an order of magnitude higher (in 2016 and 2017) than the other three representative monitoring wells, ranging from 147,000 to 189,000 µg/L. However, the overall trend for these four monitoring wells is that they are dominated by a mix of iron-reducing and sulfate-reducing conditions, which are more reduced than the above-described background wells. The ORP values reported for these four monitoring wells typically fall within the range expected for a system dominated by iron-reducing conditions, and thus support the groundwater geochemistry.

The geochemistry of areas impacted by high concentrations of benzene, but outside regions targeted for ISCO treatments, are represented by MW-273 (SWMU 17) and MW-374 (PAOC 46). Although other monitoring wells (such as MW-122 [NF4-2]) are present in areas suitable for assessment, no data exist for those wells for 2016 or 2017. For the two representative monitoring wells, both were depleted in nitrate after 2015. Ferrous iron was depleted for some sampling dates in MW-273 but ranged from 961 to 5,260 µg/L for other dates. Ferrous iron concentrations in MW-374 were within the range demonstrated for MW-273. Sulfate concentrations were close to depleted for all sampling dates for MW-374 and for most sampling dates for MW-273. The highest sulfate concentration for MW-273 was 3,090 µg/L in 2016. For MW-374, the highest sulfate concentration to date for this monitoring well (30,700 µg/L) were reported during the most recent sampling date (February 2018) (**Appendix B**). As such, monitoring wells within non-ISCO-impacted areas of high benzene concentration were much more reduced than those where low levels of benzene were found, likely dominated by either sulfate-reducing conditions or a mix of iron-reducing and sulfate-reducing conditions. This is supported by ORP values for these three monitoring wells. This trend of more reduced geochemistry associated with high concentrations of organic contaminants is a classic fingerprint of MNA.

4.3.3 East Yard

Similar to the Main Yard, the East Yard has had repeated ISCO events to break down targeted areas of high benzene concentrations. The East Yard also experiences possible tidal influences, since the eastern boundary is the Arthur Kill. Although the extent of these possible tidal influences is unresolved at this time, these tidal influences can easily disrupt the typical fingerprint of hydrocarbon MNA because fresh nutrients are regularly washing into an effected area (Chevron 2008a). In addition, non-contaminant organic matter can wash into the system, providing material for the indigenous microbial population to

degrade in preference to hydrocarbon contaminants, but which will cause depletion of the TEA markers typically used for indirect MNA monitoring (Chevron 2008b).

Background conditions in less tidal areas are represented by MW-141 (SWMU 42) and MW-145 (AOC 27). These wells demonstrate nitrate levels that ranged from depleted (MW-145) to 2,700 µg/L (MW-141) in 2016 and 2017. The highest nitrate concentrations were consistently detected in MW-141. Ferrous iron concentrations were low, ranging from being depleted to 313 µg/L in 2016 and 2017. Sulfate levels were elevated in the two monitoring wells for this period, ranging from 98,400 to 118,000 µg/L. Background monitoring wells that are under a possibly increased level of tidal influence, represented by MW-144 (AOC 14), MW-155R (AOC 29), and MW-253 (AOC 14), show depleted nitrate concentrations. Ferrous iron concentrations were higher than found in the less tidal background wells, ranging from 17,800 to 326,000 µg/L during 2016 and 2017. Similarly, sulfate concentrations were higher in more tidal background wells, ranging from 54,200 to 2,260,000 µg/L during this time period. Thus, the general trend is for background wells to be under the influence of nitrate reducing conditions. However, ferrous iron and sulfate concentrations are higher in those background wells that are more under a tidal influence than those that are not, suggesting that there may be an influence of iron-reducing conditions as well in these monitoring wells.

Monitoring wells in low benzene concentration areas possibly impacted by ISCO are represented by MW-236 (AOC 27), MW-245 (SMWU 42), and MW-251 (between AOC 6C and SMWU 3, near PAOC 69) and report nitrate levels similar to those found in background wells. From 2016 through 2017, ferrous iron concentrations ranged from 317 to 23,300 µg/L, falling between concentrations found for background wells. Comparable sulfate concentrations ranged from 21,700 to 180,000 µg/L, which are similar to values found in less-tidal background wells. Thus, these wells appear to be dominated by different anaerobic processes that range from nitrate-reducing to mildly iron-reducing conditions.

Benzene concentrations are high in MW-270 (AOC 31). ISCO was performed in areas surrounding this monitoring well in 2015 and again in mid-2017 into 2018. Nitrate concentrations in MW-270 were depleted. Ferrous iron concentrations in MW-270 ranged from 74,900 to 113,000 µg/L in 2016 and 2017. Sulfate concentrations are similar to those detected in areas of lower benzene concentration. Thus, in contrast to the Central Yard and Main Yard, the classic fingerprint of MNA is not nearly as clear in the East Yard. Instead, as demonstrated by the background monitoring well data, there may be an influence of tidal forces on the geochemistry detected within the East Yard. If true, these repeated pulses of fresh nutrients into the East Yard could blur the traditional pattern of TEA depletion when microbial processes dominate natural attenuation. In addition, historical ISCO events may have impacted areas farther from the injection areas than initially thought, affecting the groundwater geochemistry in some of the discussed wells. Furthermore, many of the tank basins within the East Yard are unlined and regularly flood. The impact that this has on MNA parameters is unclear. This is not to say that biological attenuation is not occurring in the East Yard. Instead, the data suggest that using traditional geochemical parameters to monitor biodegradation will be less effective in the East Yard than in other regions of the Facility. As such, this may be an area to strongly

consider for the application of the below-described in-situ microcosms for the direct evaluation of benzene biodegraders.

4.4 A Review of the Lines of Evidence Approach to Support MNA

MNA is a widely accepted technology for contaminant remediation (Young and Mulligan 2003). It has been successfully used across the globe for a wide range of contaminants, including those found at this Facility. Basic protocols for monitoring biological natural attenuation have also been outlined for decades by organizations such as the USEPA and the US Air Force (Wiedemeier et al. 1999).

A literature search conducted through the National Center for Biotechnology Information (NCBI) literature database, conducted in June 2018, resulted in just under 16,000 peer-reviewed manuscripts when using the keywords “hydrocarbon” and “bioremediation” (NCBI 2018).

This search of the peer-reviewed literature also does not capture professional presentations or the hundreds of scientific books published on this topic. Thus, the large volume of peer-reviewed manuscripts listed in the above database search significantly underestimates the volume of knowledge on this topic as well as its acceptance by the scientific community. With the advent of molecular microbiology and the resulting benefits of being able to directly monitor bacterial actions without the time and labor-intensive need to culture these microbes, this rate of investigation (and thus publishing) has been ever-increasing.

As such, a full review of the topic of MNA is well beyond the scope of this document. However, it will be summarized in accordance with current technical guidance, with a focus on the biological degradation of benzene (NJDEP 2012a). Additionally, an assessment of available in-situ benzene biodegradation rates will be conducted. Finally, a discussion of the possible use of in-situ microcosm (Bio-Trap®) samplers will be conducted as part of an evaluation of possible ways to obtain direct, quantified data regarding the indigenous biodegradation of benzene at the Facility.

4.4.1 Occurrence and Effectiveness of MNA of Petroleum Hydrocarbons as Documented in Literature

Ward et al. (1980) was one of the first manuscripts to report that indigenous microbes played a significant role in breaking down (or “weathering”) many of the components of crude oil, including benzene. The effectiveness of this biodegradation was found to be based on both the chemical structures of the individual components and the different microbial activities occurring in aerobic and anaerobic environments. However, a specific hydrocarbon’s bioremediation efficiency and effectiveness was realized to also be strongly impacted by the presence of other hydrocarbons or site constituents (Atlas 1991; Jennings 2005; Ollivier and Magot 2005; and Vogt et al. 2011).

The introduction of modern molecular and stable-isotope technologies has significantly increased the understanding of in-situ benzene biodegradation, particularly at complex sites where multiple contaminants are present (Chakraborty and Coates 2004; Cupples

2011; Liang et al. 2013; and Mancini et al. 2008). What has become clear, and scientifically accepted, is that in-situ bioremediation is a known mechanism to successfully achieve benzene removal at sites where conditions are similar to those found at this Facility.

4.4.2 *Average Biodegradation Rates for COCs Documented in Numerous Case Studies*

As eluded to above, there are several factors that can significantly impact the rate of biodegradation for any particular hydrocarbon, including:

- Environmental redox conditions
- Availability of needed macro- and micro-nutrients
- The presence of other hydrocarbons, and the type of hydrocarbons present
- The presence of other, non-hydrocarbon co-contaminants
- The concentration of the target hydrocarbon

As such, trying to accurately predict the biodegradation rate of a hydrocarbon in a particular environment is extremely difficult (Ollivier and Magot 2005). However, some generalizations can be made.

Focusing on the benzene, toluene, ethylbenzene and xylene compounds, benzene is typically the slowest constituent to biodegrade (Edwards 2018). This is because its simple aromatic ring structure has no clear place for metabolic enzymes to start their action. This is one reason for the wide range of strategies derived by those microbes capable of cracking open the strongly-bonded ring structure. Under nitrate-reducing conditions, benzene biodegradation has been measured between 0.1 and 0.4 milligrams per liter per day (mg/L/day). Under sulfate-reducing conditions, this rate is approximately 0.1 to 0.3 mg/L/day. Methanogenic conditions result in the lowest amount of energy gained from benzene metabolism, and thus rates are expected to be the slowest. However, methanogenic benzene biodegradation rates have been reported to be between 0.3 and 2.0 mg/L/day, generally in the presence of a consortium of degrading microbes. However, for comparison purposes, toluene and O-xylene can degrade at a rate of over 10 mg/L/day under methanogenic conditions. Methanogenic toluene and O-xylene biodegrading cultures have a doubling time that is 1/2 to 1/3 that of benzene degrading cultures, even those acting in nitrate-reducing conditions (Edwards 2018).

4.4.3 *Discussion of Case Studies Where ISCO and Other In-Situ Remedies Have Been Followed by MNA*

Several in-situ contaminant remedies have successfully been followed by MNA. In fact, MNA is such a common polishing method for most contaminants that it has almost been assumed to be a final step for environmental cleanup (Neilson and Allard 2008; Ollivier and Magot 2005; Tally 2006; Wackett and Hershberger 2001). As such, a full description of these case studies is beyond the scope of this document.

In summary, it has been successfully demonstrated that MNA can follow ISCO in an attempt to biodegrade remaining contaminants. Although the addition of oxidant can initially decrease the diversity and size of an indigenous microbial population, rebound

does occur and subsequent natural attenuation has been found to re-establish itself (Polli et al. 2018). This has been observed with multiple ISCO compounds, and the negative impact of the oxidant can be tempered by modifying the application methods of the oxidant (Fedrizzi et al. 2017). However, this rebound of MNA processes may also be dependent on the type of bacteria present. For example, a longer-term rebound period for indigenous degraders was observed during ISCO treatment for chlorinated solvents, compared to studies that looked at hydrocarbon-degrading microbial populations (Sutton et al. 2015).

Thus, ISCO does not permanently prevent benzene biodegradation. However, it may temporarily impact bioattenuation. The degree and length of time that benzene biodegradation is affected by ISCO likely is based on a number of site-specific parameters, such as:

- Site geochemistry
- Type of oxidant used
- Concentration of oxidant injected
- Total volume of oxidant injected
- Type of contaminant being targeted by ISCO
- Concentration of target contaminant being targeted by ISCO
- The presence, and concentration of, any co-contaminants
- The composition and size of the indigenous microbial population targeted for MNA

4.4.4 *Possible Assessments for Direct Microbial Evidence of In-Situ Benzene Biodegradation*

A substantial amount of valuable, site-specific information could be gleaned through the use of certain molecular technologies that would directly monitor the benzene-degrading population at this Facility. Specifically, using in-situ microcosms (also commercially known as Bio-Traps®), or micro-array technologies. Unlike the use of stable-isotope technologies, which can prove that biological attenuation is occurring, the use of these assessments will provide additional information about the indigenous benzene-degrading microbial population.

In Situ-Microcosms (Bio-Traps®)

Bio-Traps® are the proprietary in-situ biological sampler made by Microbial Insights, Inc. (MI). Each is composed of a perforated polyvinyl chloride (PVC) tube, capped off at each end, and filled with a few hundred BioSep™ beads. BioSep™ beads (also proprietary to MI) are made of an activated carbon and Nomex mixture, which has not just been sterilized but instead has been heated until all residual biomarkers are burned off. Once the beads have been both sterilized and cleaned of residual biomarkers, they are “baited” with an isotopically labeled target compound (benzene).

These beads are then packed into the sterile Bio-Trap® PVC housing, and the resulting sampler is placed into the targeted monitoring well, where indigenous groundwater microbes will enter the bead’s pore spaces. The presence of a carbon source (isotopically-labeled benzene), coupled with the high degree of porosity of the beads, will attract

indigenous microbes to enter the beads once the samplers are put into groundwater. These resident benzene-degraders will then start metabolizing the labeled benzene that was sorbed to the beads, and the isotopic label will be subsequently transferred from the benzene into the degrader's biomass.

After a few weeks, the Bio-Trap® is removed and sent back to the MI laboratory. After opening the Bio-Trap® PVC housing, half of the beads are sent to one laboratory for geochemical assessments. For those getting tested for geochemistry, multiple metrics are measured, including:

- How much isotopically labeled carbon dioxide was captured within the beads (the carbon dioxide being generated from the labeled benzene being fully mineralized); and
- How much of the labeled benzene remains?
    - From this, it can be calculated how much benzene was consumed during the deployment timeframe, and thus, an in-situ degradation rate can be calculated.

The other half of the beads taken from the sampler go to another laboratory for biological testing. These beads are first washed, removing all bacteria that had inhabited the beads (benzene degraders and other non-degraders that were also indigenous) during deployment. The number of cells containing the isotopic tag are then counted. Because the only way this tag could become present in microbial biomass is by the bacteria consuming the tagged benzene, the size of the indigenous benzene-degrading population can be calculated. Finally, the laboratory also investigates the total indigenous population of the targeted monitoring well, including those bacteria that did not metabolize the target, isotopically-labelled compound. Specifically, certain molecules within the cell membranes of these microbes are analyzed. From this assessment, the following information can be learned:

- A full profile of the major groups that make up the indigenous microbial community (fermenters, anaerobes, proteobacteria, and others);
    - The diversity of the overall indigenous community is related to the health of this community
- How stressed out the benzene-degrading microbial community is; and
- If this microbial stress is because of the presence of something toxic, or if the stress is likely due to lacking a required nutrient.

All the above in-situ microcosm data, biotic and abiotic, are quantitative.

Quant-Array (Petroleum) Analysis

A Quant-Array (Petroleum) analysis is proprietary micro-array technique that includes a modified version of a technology called a quantified polymerase chain reaction (qPCR). The Quant-Array (Petroleum) analysis is an "off the shelf" assessment designed to target 22 pre-selected genes commonly important to monitoring petroleum-impacted sites.

These 22 genes, all targeted for quantification, include (but are not limited to) those associated with a variety of aerobic and anaerobic benzene-degradation pathways. In addition, genes associated with the bioattenuation of polyaromatic and alkane hydrocarbons are quantified. This is important because the bioattenuation of these compounds may act in either a complimentary or competitive manner to benzene-specific bioattenuation. Finally, the total microbial population is quantified, as are the number of sulfate-reducing bacteria.

Facility-specific questions that can be answered by the Quant-Array (Petroleum) technology include:

- Are benzene-degrading bacteria present?
- If benzene-degraders are present, what is the size of the population?
- Are population sizes different between one area of a site and another (such as within and outside of any excavated areas)?
- Regarding monitoring site efforts, has the size of a target population changed as a result of site modification efforts such as a bionutrient augmentation process?
- Are specific benzene-degrading mechanisms (such as aerobic or anaerobic processes) occurring and to what degree?
- Is the biodegradation of other site hydrocarbons competing for microbial resources?

Proposed Direct Microbial Assessment Plan

It is suggested that both the in-situ microcosm (Bio-Trap®) and the Quant-Array (Petroleum) analyses be used in tandem, maximizing fiscal responsibility and the amount of Facility information gleaned. This takes advantage of the different strengths of each assessment. Because Quant-Array (Petroleum) analyses would involve a single groundwater grab sample, these could be pulled from certain Facility monitoring wells while other monitoring wells can be targeted for in-situ microcosms.

The key to understanding the current state of MNA at the Facility involves comparing various regions of a targeted plume: the outer periphery, areas of middle-level concentrations, and the plume core. This is because MNA works from a plume periphery inward toward the core. By understanding the microbial activity and any challenges faced by this microbial activity at the periphery and in zones of mid-range benzene concentrations, information can be deduced regarding what to expect when this activity reaches the center of a plume. For example, if the microbial activity appears to be challenged by a lack of specific nutrients in areas of higher activity (the plume periphery), appropriate plans can be made regarding possible nutritional amendments. The location of these amendments could include areas near the plume periphery as well as areas where MNA has yet to start (such as the plume core). This would make it easier for degrading microbes to begin acting in zones of higher concentration than just at the periphery, resulting in a more aggressive removal of benzene mass that would otherwise contribute to this periphery zone.

A formal microbial assessment plan would require a more detailed assessment of targeted monitoring wells of not only current biochemical parameters but also an evaluation of groundwater recharge rates and other geologic information that would prove critical for each of the analyses. For example, confirmation would be needed that any well targeted for an in-situ microcosm sampler would possess a tall enough water column to support the sampler for the entire length of the deployment time. As CM implementation and post-implementation monitoring are completed across the Facility, monitoring wells will be identified for microbial assessment. The following areas will be evaluated for the potential for microbial assessment:

Central Yard

- AOC 25
- AOC 36

Main Yard

- AOC 5/7/44
- AOC 6A/SWMU 35
- AOC 9A
- AOC 8/15
- AOC 33/34
- AOC 41
- SWMU 21/43
- SWMU 40

East Yard

- AOC 6B/29
- AOC 6C/13/SWMU 8
- AOC 14/26
- AOC 27/35/SWMU 10
- AOC 37
- AOC 38/39
- AOC 50

To provide baseline data, microbial assessments will be considered in some areas where CM implementation has not yet begun. CM remedies, such as excavations and trenching, are completed in a relatively short time. Therefore, the type of coordination with any direct microbial analyses would likely be different than the type of coordination needed for a CM remedy such as ISCO implementation.

The resulting data would provide detailed, quantified information about the health and activity level of indigenous benzene degraders. Quantified comparisons of the indigenous benzene degraders can be made between Yards, or between areas within a single Yard.

When compiled, this information can help discern, for example, if benzene biodegradation in some areas would benefit from nutrient or biological amendments. If warranted, then information would be known about what amendments should be considered for what areas to maximize performance. This is information not provided by stable-isotope assessments. Equally important would be determining if no intervention is needed. If MNA is found to be functioning well in an area of the Facility, there may be no reason to perform any effort other than inexpensive, routine monitoring. Proper data would allow this condition to be both confirmed, and properly documented.

A final benefit of in-situ microcosms would be that they provide very robust baseline microbial activity and health data, against which future data can be compared if changes are observed in apparent benzene MNA patterns. The most useful information from the Quant-Array (Petroleum) assessment would include information about what metabolic pathways were being utilized by indigenous benzene biodegraders, as this would allow for information about possible treatments to enhance this activity. In addition, information would be known about other indigenous hydrocarbon degradation pathways - information that would be very helpful in areas where benzene-specific MNA has yet to take hold. The primary benefit of the in-situ microcosm samplers is that current, in-situ benzene biodegradation rates could be obtained. This information would be particularly useful when long-term MNA solutions are being considered.

Facility conditions are known to match those that would support long-term benzene biodegradation and MNA activities. In addition, indirect Facility information (such as geochemical data) shows that MNA is occurring in many areas and will likely occur in areas currently undergoing active CM implementation. As a result of more direct microbial information, however, direct MNA monitoring and documentation could occur.

4.4.5 *Estimates of Biodegradation Rates Based on Historical (Pre-ISCO) Concentration Data*

There are no direct bioattenuation data available at this Facility. Instead, currently available data include estimates of benzene mass present at various times and estimates of benzene mass lost during ISCO or excavation events. At best, this information can provide an estimate of total benzene mass removal over a period of time. However, in order to accurately quantify a rate of biological degradation, additional information would be needed regarding how much of this benzene loss had been associated with biological activity. Unlike stable-isotope assessments, which can confirm that benzene biodegradation is occurring, the rate of benzene biodegradation cannot be accurately calculated with stable-isotope tools.

However, this is something that can be determined for current site conditions.

Direct biological monitoring, using in-situ microcosms as proposed above, will generate a current in situ benzene biodegradation rate. When the microcosms are strategically placed around the Facility, information can be gleaned about biodegradation rate differences between Yard and between areas within a given Yard. As described above, this information can assist with future yard maintenance, can help design biodegradation enhancements, and will act as quantified baseline data for future monitoring.

These benefits could be achieved both for areas where ISCO has been applied as well as areas where ISCO has never occurred.

4.5 Summary of Conclusions, MNA Analysis

An evaluation of MNA at the Facility indicates that natural attenuation processes are occurring. MNA has been active even when bulk material removal (through a variety of CM remedies) was occurring in more heavily-impacted areas of the Facility. This is based on the following:

- Benzene has been largely contained on site over decades of time.
- Benzene concentrations and footprint size is decreasing, including areas not targeted by any active reduction methods such as ISCO and excavation.
- MNA geochemical indicators support that site conditions are favorable for MNA and demonstrate a clear fingerprint of active MNA.
- Benzene biodegradation is known to occur at the Facility.

A comparison of the footprint of various concentrations of benzene over the past 10 years shows that the contaminant remains contained on site (**Figure 10**). As important, concentrations continue to decrease, even in areas where active remediation has not occurred. Furthermore, the actual benzene footprint has decreased. This is particularly true in areas of mid to lower benzene concentrations, which would be the most amenable to biodegradation.

An assessment of MNA geochemical parameters for each of the three yards shows that a clear fingerprint of biological hydrocarbon degradation is present. The observed, overall trend is that background monitoring wells demonstrated the least reduced environments. The degree of reduction increased as benzene concentrations increased. This was consistently supported by current benzene concentrations as well as multiple MNA geochemical parameters, including concentrations of nitrate, ferrous iron, sulfate, and reported ORP values. This fingerprint is not seen if only abiotic processes are degrading site contaminants.

Methane was not a helpful MNA marker at the Facility because none of the targeted monitoring wells were reported to be dominated by methanogenic conditions. The production of sulfide during sulfate-reduction processes proved to be an inconclusive metric, since reported sulfide concentrations varied widely over time and between monitoring wells. This is likely an effect of sulfide being highly reactive, particularly in environments such as this where various forms of iron are present, often resulting in the precipitation of sulfide as iron sulfides. Thus, sulfide concentrations do not always reliably reflect environmental conditions.

Finally, it should be noted that groundwater at the Facility is not being used as potable water. Therefore, there is no specific time constraint for the groundwater to achieve compliance in an expedited manner that may otherwise warrant enhanced CMs.

5.0 CORRECTIVE MEASURE TECHNOLOGY SUMMARY

5.1 General Overview

USEPA (1999) defines natural attenuation as the biodegradation, diffusion, dilution, sorption, volatilization, and/or chemical and biochemical stabilization of contaminants to effectively reduce contaminant toxicity, mobility, or volume to levels that are protective of human health and the environment (1999). Typically, MNA is used in conjunction with active remediation. At the Facility it will be implemented as a CM for groundwater with concentrations ranging from 1 µg/L to 100 µg/L. Above this concentration, active remediation such as ISCO will be employed to bring concentrations within this range, where MNA will subsequently take over as the primary remedy.

Geochemical data from the monitoring wells located in the Main Yard, East Yard and Central Yard of the Facility were analyzed. Approximately 320 wells throughout these yards were sampled and analyzed for groundwater geochemical (MNA) parameters between 2014 and 2018. These data were analyzed to confirm that MNA will effectively reduce low levels of organic contamination in the groundwater.

5.2 Source Control

A key component of successful MNA is that the influx of new contaminants is controlled either through containment, removal, or treatment, so that it is no longer contributing to the dissolved phase. This is currently being conducted in select areas through the implementation of ISCO or similar remedies, as described above. Progress with ISCO treatments will be reported in ISCO-specific documents and communications, as opposed to within this MNA-specific document.

As already described in detail within this report, a comparison of benzene concentrations over the last 10 years shows that areas of high contamination have significantly reduced in size. The remaining areas of low concentration are prime targets for biological attenuation, and over time will shrink in size as the indigenous microbial population consumes site constituents. This suggests that the existing groundwater plumes are stable and have the potential to attenuate after adequate mass reduction is accomplished.

5.3 Institutional Controls

Institutional controls may be appropriate to protect human health and the environment in areas where soil and groundwater contaminant concentrations will exceed applicable criteria/standards following the application of a CM. Institutional controls are non-engineering measures, such as administrative and/or legal controls, that help minimize the potential for human exposure to contamination by limiting the land use in the area to which it was applied. Institutional controls include deed restrictions for impacted soil and CEAs for impacted groundwater. CEAs are established to provide notice that the groundwater quality standards for an aquifer classification are not or will not be met in a localized area due to natural water quality or anthropogenic influences. Designated aquifer uses are suspended in the affected area for the term of the CEA to ensure that the uses

of the aquifer are restricted until the GWQSs are achieved, thereby limiting the potential for human exposure.

N.J.A.C. 7:9-6 (New Jersey GWQS) provides the basis for the protection of groundwater quality through the establishment of constituent standards for groundwater pollutants. The standards impact all site remediation cases where groundwater contamination exceeds the standards applicable to the groundwater classification area in which the site is located. The Facility is in a Class-IIA aquifer, and groundwater quality standards are summarized in Table 1. The Farrington Aquifer near the Facility is designated as Class IIIB groundwater, which is not suitable for conversion to potable uses. Groundwater is not used as a source of water supply within at least two miles of the Facility.

6.0 REVIEW OF CURRENT MONITORED NATURAL ATTENUATION PROGRAM

This section provides a general outline of the monitoring program (i.e., performance monitoring that has been implemented as part of the MNA CM). The goals of this review of ongoing MNA efforts are:

- Evaluate the performance of the MNA CM
- Determine the effort needed to achieve the cleanup goals
- Ensure safe and successful implementation of the MNA CM

As part of the monitoring program, at a minimum, groundwater samples will still be collected from upgradient, within and downgradient of the impacted areas. The monitoring well locations for the monitoring program are selected such that the contaminant concentrations within and downgradient of the impacted zones can be evaluated and compared to the corrective measure objectives.

The quality assurance and quality control (QA/QC) for the monitoring program was established as part of the Corrective Measures Implementation Field Sampling and Analysis Plan/Quality Assurance Project Plan (FSAP-QAPP) (Chevron 2016).

6.1 Data Gaps

The overall current monitoring plan does allow for some questions about Facility MNA to be answered. However, many questions still remain, such as:

- What is the specific effect of ISCO events on indigenous benzene biodegradation populations, including how long does this population take to recover from exposure to ISCO treatments?
- What is the indigenous benzene-degrading rate at various locations within each Yard of this Facility?
- How healthy and active are the native benzene biodegraders?

Some of these identified data gaps can be addressed while CM activities are occurring; however, others will need to wait until CM implementation completion has been achieved. Trends for benzene degradation through MNA cannot be accurately calculated during active remediation. Additionally, remediation methods such as ISCO and ISS/ESS can temporarily alter the geochemistry by removing benzene mass, and by amending groundwater parameters by adding oxygen and sulfate.

In summary, for some areas of the Facility, adequate long-term MNA data are available. However, other areas of the Facility are still in the process of achieving this long-term trend reporting. Despite not having a complete MNA profile of the entire Facility:

- Strong data are available to show that Facility conditions are correct for MNA to occur;
- Multiple lines of evidence show that MNA is occurring at the Facility; and

- Conditions are good for MNA to begin in Facility areas where active CM implementation is currently occurring.

As such, there is a very high degree of confidence that MNA will be a successful step throughout the Facility, and MNA is a reasonable step in the process of meeting Facility endpoints.

6.2 Performance Monitoring

Groundwater monitoring will continue to be conducted to determine the concentrations and distribution of contaminants, geochemical parameters, and MNA related parameters (e.g., alkalinity, pH ORP, sulfides, dissolved iron, total iron, DO, and nitrates). The data collected during performance monitoring will be used for the following purposes:

- Evaluate treatment effectiveness of the MNA CM
- Monitor groundwater quality within and downgradient of the MNA areas
- Determine whether cleanup goals have been achieved
- Monitor downgradient migration of contaminant(s) and, if appropriate, daughter products
- Evaluate the persistence/attenuation period of the COCs and, if appropriate, daughter products

Groundwater monitoring frequency and location plan has been developed and is provided in **Appendix C**. The frequency and location of performance monitoring events has been determined for each treatment area based on the size of the treatment area, anticipated benzene degradation rates, chemical and geochemical changes observed historically, and the timeframe necessary to achieve CM objectives/regulatory requirements.

The suite of contaminant, geochemical, and MNA parameters to be assessed for each monitoring well being sampled is also detailed in **Appendix C**. For long term MNA evaluation, all MNA parameters and VOC data from an individual well should be acquired on the same day (or at least within the same few days). This will make data evaluations more accurate by eliminating variables such as weather events and disturbances due to high purge rates used for other COCs.

During groundwater sampling, testing, and reporting, established standard operating procedures in the FSAP/QAPP (Chevron 2016) will be followed.

Ongoing MNA activities should be performed in coordination with mass reduction efforts, such as ISCO or other means. A table of injections, locations of injections (including a map to compare injection locations with monitoring well locations), type and concentration of injected material, and anticipated radius of influence of each ISCO event, and other CM technologies will be incorporated into the MNA tracking until CM implementation is complete. Mass removal activities will be summarized in future MNA CM Progress Reports, as detailed in Section 7 of this document.

In addition, a formal evaluation should be conducted to determine the feasibility of using the above-described direct methods to directly evaluate, monitor, and quantify information about the indigenous benzene-degrading microbial community. The goal of this evaluation is to identify the level of effort needed for such a Facility analysis, while also determining the project benefits (such as understanding the distribution of indigenous benzene degraders, the health of this microbial population, and having quantified benzene biodegradation rates for various locations at the Facility). This evaluation should include:

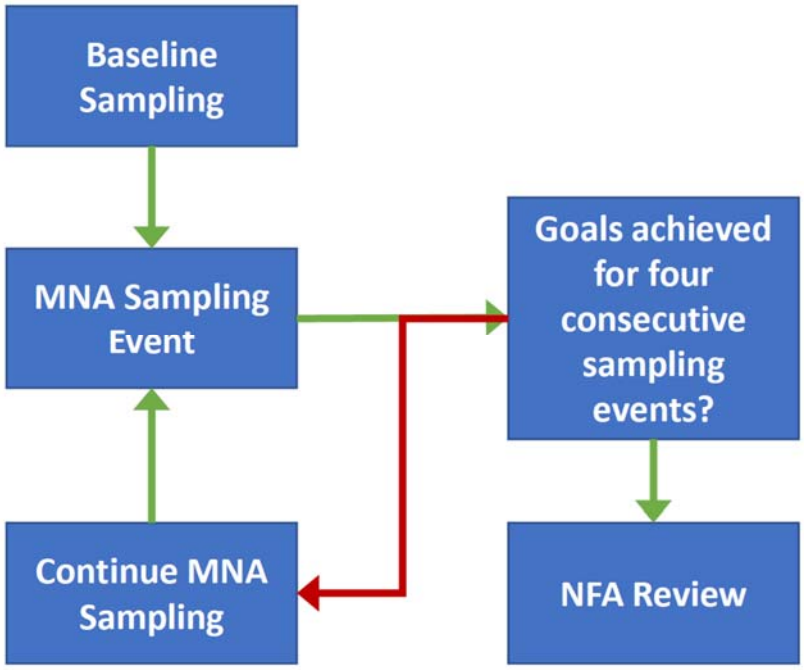
- Recommended locations for Quant-Array (Petroleum) groundwater grab samples
- Recommended locations of Bio-Trap® sampler placement within each Facility yard
- Estimated laboratory, data analysis, and reporting costs
- Expected benefits to each yard and the Facility as a whole

This report contains an introduction to these proposed, direct-monitoring technologies along with a guidance that both areas of higher benzene concentration as well as periphery zones be assessed. These areas are targeted due to ongoing benzene impacts, a desire to determine the extent of current MNA in these regions, and information about possible mechanisms to enhance or better monitor this MNA.

In summary, MNA is known to occur in environments found in many regions at the Facility. In Facility areas where MNA has been monitored to a less degree, geochemical conditions match those that would be expected to support MNA activities. The current goal is to conduct ongoing CM activities in such a way that MNA can subsequently be initiated in a manner that is as effective and efficient as possible.

6.3 MNA Corrective Measures Completion

The overall goal of data collection during performance monitoring is to assist in tracking the progress of the remediation. The data obtained during the performance monitoring will be evaluated using the process depicted below:



Once the performance monitoring results confirm the MNA CM objectives have been achieved, Chevron will evaluate the area for an NFA determination for groundwater. An NFA request will be made when an area has maintained benzene concentrations under 1 µg/L for four consecutive sampling events. NFA requests will be provided as part of the biennial CEA Certification Report.

7.0 DOCUMENTATION AND APPROVAL PROCESS

7.1 Data Management

The data management process includes procedures necessary to ensure consistent and complete collection of field data, tracking of laboratory analytical data and data validation status, consistent and timely production of electronic data deliverables (EDDs) from participating laboratories, and accurate and timely entry of EDDs into the Environmental Information Management (EIM) database. The EIM database is a computerized database management system that will be employed to manage and organize the field and analytical data that will be generated during the life-cycle of the MNA CM for the Facility. The Facility Data Management Plan (DMP) (Chevron 2017b) will continue to serve as a general standard and guideline for all data management practices. The DMP establishes procedures that will be followed to plan, collect, create, and track data collected as part of MNA implementation.

7.2 Documentation Requirements

Parsons will continue to document field activities in field log books dedicated to the MNA CM. During MNA implementation, a groundwater sampling log will continue to be maintained to record daily sampling activities, including such parameters as location, groundwater parameters, sample data. In addition to this IWP, implementation of the MNA CM will include preparation and submittal of an annual Corrective Measure Progress Report to USEPA and NJDEP for their review and approval.

An annual MNA CM Progress Report will be submitted for calendar years 2019 and 2020 and will include information on the implementation of the MNA CM at the Facility during the reporting period. The CM Progress Report will contain the following information specific to MNA:

- Summary of the field activities completed
- Summary of data obtained
    - Groundwater sampling results
    - Well completion details
    - Summary of field measurements
- Summary of the MNA implementation
    - Evaluation of collected MNA parameter data
    - Evaluation of MNA treatment effectiveness (e.g., COC trends)
    - Evaluation of any secondary effects (e.g., daughter products, evidence of new releases)
    - Deviations from the approved IWP
- Evaluation of analytical data
- Summary of the impact of ISCO and other mass reduction measures on MNA

- Summary of any findings from evaluating the use of in-situ microcosm samplers (Bio-Traps®), as well as a summary if the actual Bio-Trap® study is conducted
- Summary of any other MNA results obtained in conjunction with ISCO activities
- Conclusions and Recommendations

When implementation of CMs have been completed in 2020, biennial sampling will be conducted consistent with the requirements of the CEA Remedial Action Protectiveness/Biennial Certification. The CEA biennial certification will be submitted beginning two years after the CEA is approved.

8.0 HEALTH AND SAFETY

This section provides details about the health and safety aspects of MNA implementation.

A comprehensive health and safety plan was developed prior to the initial field implementation of the MNA CM. The plan included job safety analyses (JSAs), standard operating procedures, emergency procedures, and site security requirements.

For current and future MNA sampling events, a daily tail gate safety meeting and JSA review will be conducted as part of field implementation at individual AOCs and SWMUs.

The Facility is not accessible to the general public and is subject to stringent site access controls including fencing, security gates, and security patrols.

9.0 PERMITTING

This section describes the permits that have been identified as being necessary for the MNA CM.

9.1 Modified HSWA Permit

Chevron is currently conducting CM activities under the 2013 HSWA Permit Renewal from the USEPA. The HSWA permit outlines the selected remedy and scope of MNA CM.

10.0 PROJECT MANAGEMENT APPROACH

This section describes the project management approach including levels of authority and responsibility of parties who will be involved in the MNA CM design and implementation.

The USEPA is currently the lead regulatory agency and provides oversight of environmental cleanup performed by Chevron and its contractors in accordance with the requirements defined in the HSWA Permit Renewal. The USEPA will issue a CA 550 for the MNA CM upon completion of active remediation and demonstration that MNA is occurring as described in this IWP. The MNA CM may continue after the CA 550 is issued.

Chevron is the current responsible party for the environmental cleanup at SWMUs and AOCs included in the HSWA Permit Renewal. Chevron will oversee design, implementation, selection of appropriate contractors, selection of a NJDEP-certified laboratory for sample analysis, and coordination with the regulatory agencies.

Parsons has been selected by Chevron to manage and implement CMs across the Facility as recommended in the CMS, including the MNA CM. Parsons is responsible for the preparation of this IWP, implementation of the MNA CM, and preparation of the annual CM Progress Report.

Buckeye currently owns and operates the Facility and will be responsible for providing Chevron with unrestricted access to the areas that require the MNA CM.

11.0 WASTE MANAGEMENT PLAN

Waste generated during the MNA CM implementation and monitoring activities will be managed and disposed in accordance with federal, state and local regulations. The Chevron Perth Amboy Facility Waste Management Plan, Version 1.0 (Chevron 2017a) provides specific details of staging, handling, characterization and disposal procedures.

The following types of waste are anticipated during the implementation of MNA CMs:

- **Decontamination and purge water** - Decontamination and purge water will be generated during equipment cleaning and groundwater sampling.
- **Used personal protective equipment (PPE) and disposable sampling equipment** - Small quantities of used PPE and disposable sampling equipment (e.g., tubing, plastic spoons) will be generated during field activities.
- **General refuse** – site activities will result in generation of general refuse such as paper towels, shipping/storage containers for amendments, shipping pallets, plastic bags, and paper sacks.

12.0 PROJECT SCHEDULE

The overall project schedule is contingent on multiple factors, including USEPA and NJDEP review and approval of this IWP. Detailed schedules for MNA implementation at each SWMU and AOC will be provided in future area-specific submittals. All proposed schedules are based on the assumption that unrestricted access to the Facility and areas where the MNA CM is being implemented is/will be available to conduct the field activities. The schedule may need revisions based on factors that are beyond Chevron's control. If necessary, the schedule will be updated annually as part of the annual CM Progress Report.

MNA Field and Reporting Activities Schedule

Timeframe	Sampling	Reporting
1Q 2019 – 4Q 2020	Quarterly	Annual
2021-2028	Biennial	With Biennial CEA Certification
>2028	Biennial until all MNA goals are achieved.	With Biennial CEA Certification

If the proposed dates or length of time for the above tasks require adjustment, Parsons will make the necessary adjustments and update the schedule.

LNAPL PROPERTIES			
LNAPL Area Name	**Type of LNAPL**	**Specific Gravity**	**Viscosity**
SWMU 8	Various isomers of C12 alkylated benzenes including dodecylbenzene with plasticizers including dioctylphthalate and triarylphosphates, mixed with highly weathered crude oil.	0.9075	7.631b
SWMU 40	[1]No. 2 diesel range distillate and crude oil.	NM	NM
SWMU 41	[1]Refinery intermediate in gas oil range.	NM	NM
SWMU 43	Crude oil, gasoline and diesel.	0.9047 & 0.88	21.7d & 7.832b
AOC 8-NF6	Type 1 - mixture of diesel range distillate, an alkylate and a heavy oil.	0.9489	54.7a
	Type 2 - weathered crude oil.	0.9525	319.8a
	[1]Type 3 - No.2 diesel range mixed with a heavy oil.	NM	NM
	[1]Type 4 - kerosene range mixed with diesel and gas oil.	NM	NM
AOC 19	Weathered crude oil.	0.9435	260.6a
NF2	Type 1 - comprises of asphalt, and a mixture of a heavy oil, diesel range distillate and gasoline.	0.9844	20349a
	Type 2 - mixture of FCC light cycle oil, <3% gasoline and <1% heavy oil.	0.9252	11.92a
	Type 3 - 94% weathered gasoline and 6% heavy oil possibly mixed with diesel range distillate.	NM	NM
NF3	Heavy oil, gasoline and a diesel range distillate.	0.905	20.8a
NF4	Heavy oil, naphtha and a diesel range distillate.	0.9141	15.09b
NF5	Heavy oil, possibly crude, mixed with upto 40% gasoline and diesel.	0.9283	164.2a
AOC 25	North - gas oil.	0.9756	38.37c
	South - 44% diesel fuel, 33% gasoline and 22% lube oil.	0.8723	0.365b
SWMU 42	Mixture of a light cycle oil, heavy gas oil and 10% gasoline.	NM	NM
EY1	Weathered gasoline.	0.7972	0.717b
EY3	94% gasoline and 6% biodegraded distillate.	0.7864	0.717b
EY4a	Predominantly diesel range distillate mixed with gasoline and a heavy oil.	0.9369	43.3b
EY4b	Diesel range distillate and a heavy oil.	0.9049	20.7a
AOC 28	Not fingerprinted due to insufficient volume required for analysis.	NM	NM
AOC 29	Weathered No. 2 diesel oil.	0.9182	NM
State Street Parking Lot	No. 2 diesel with trace amount of gasoline.	0.87	2.963b
PAOC 15	No. 2 diesel with presence of gas oil.	0.89	120.361b
AOC 31	Weathered gasoline.	0.79	0.7564b
SWMU 10	NM	NM	NM

Notes:
a = Centistokes at 20 °C
b = Centistokes at 40 °C
c = Centistokes at 100 °C
d = Centistokes at 10 °C
NM = Not Measured because of insufficient volume or media analyzed.
[1] Fingerprinting based upon soil samples due to insufficient LNAPL required for analysis.

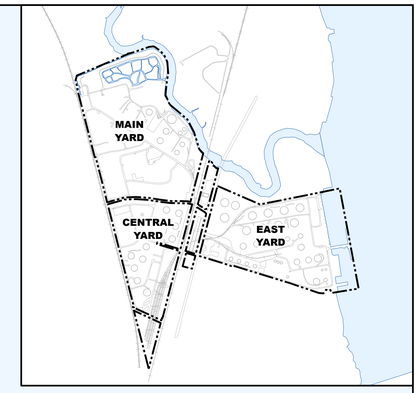
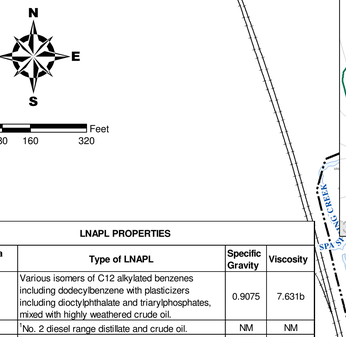
- Water Bodies



NOTES:
* The LNAPL boundaries represent areas where LNAPL has been observed previously in one or more temporary piezometers or permanent monitoring wells and verified through field investigations.
* Demarcation of varying types of LNAPL is inferred.
* AOC 29, AOC 31, AOC 8 NF 6, NF2, SWMU 43, and SWMU 8 LNAPL extents haven't been revised.
* AOC 28, EY1, EY3, SWMU 8, and SWMU 41 areas no longer show LNAPL. These revised extents have been removed.



Belt skimmer operating at PZ-0012 is actively recovering NAPL, preventing current measurements. Contours based on previously observed levels.
