SITE CHARACTERIZATION REPORT
ORTHO-CHEVRON PLANT
MARYLAND HEIGHTS, MISSOURI

Dear John:

Per your request, we are transmitting with this letter the Site Characterization Report which includes information from past Woodward-Clyde investigations at the Ortho-Chevron Maryland Heights, Missouri plant.

Please call with any questions you may have regarding this report.

Very truly yours,

Jeffrey D. Young
Assistant Project Engineer

J. D. Campbell, P.E.
Vice President

1.0 INTRODUCTION

1.1 SITE LOCATION

The Ortho-Chevron Agricultural Plant is located in an established industrial area along Adie Road in Maryland Heights, Missouri. The property is approximately 15 miles west of the greater St. Louis metropolitan area in the southwest quarter of Section 23, Township 46 North, Range 5 east (Figures 1 and 2). The site lies within the Fee Fee Creek watershed which ultimately drains into the Missouri River 5 miles to the northwest.

1.2 SITE DESCRIPTION

The site is rectangular (approximately 1300 feet by 325 feet) with the long axis orientated east-west (Figure 3). Plant facilities include office buildings, storage tanks, and two series of production buildings located adjacent to two rail spurs. A small storm water retention and spill containment pond is located near the northwest corner of the site.

1.3 PLANT HISTORY

The Ortho-Chevron Agricultural Plant has been operating at the Maryland Heights Site for over thirty years. Production processes at the site primarily consist of limited to formulating and packaging pesticides. Raw materials and finished products are shipped to and from the site by rail and truck. Past on-site disposal of wastes has occurred. These wastes may include fire debris. Few records are available indicating the locations or amounts of those wastes present at the site. Investigative work at the site has revealed buried drums and debris in some localized areas. Occasional leaks or spills of raw materials and/or products have also occurred in the past.

1.4 PAST INVESTIGATIONS

In 1981, Chevron Chemical Company initiated geohydrological investigations at the Maryland Heights site. Soil and ground water monitoring activities have also been implemented. Investigations have included installation and sampling of ground water monitoring wells, exploratory borings, and shallow soil borings. Figure 3 depicts the locations of recent exploratory borings, soil sampling locations, and ground water monitoring wells. Monitoring and investigative activities to date at the site are as follows:

1981 - Geohydrological investigation and evaluation

- 34 exploratory borings drilled
- 15 observation wells installed
- Geotechnical and chemical soil analyses
- Ground water analyses
- Field permeability tests
- Off-site drinking water well survey

1983 - Installation and sampling of 6 additional ground water monitoring wells
- Soil sampling and analysis on east and west boundaries.

1984 - Updated off-site drinking water well survey

1985 - Soil chemistry investigation along on-site railroad spur
- Soil sampling and analysis for 2,3,7,8-TCDD (dioxin)
- Building 'D' extension subsurface geotechnical investigation

1981 to present - Ongoing semi-annual or quarterly ground water sampling and analyses

2.0 SITE CHARACTERIZATION

2.1 HYDROGEOLOGY

2.1.1 Soils

The facility is situated on an eroded, gently sloping, upland loess deposit. Total relief at the site is approximately 30 feet. Natural surface drainage at the site has been altered by fill operations. Borings drilled on site indicate that some silty clay fill and rubble are present over most of the site with thicknesses up to 8 feet in some areas. Fifteen to 20 feet of loess (low

permeability silty clay) is present beneath the fill. The loess stratum in the north-northwestern and central portions of the site has been partially reworked by water in the geologic past (i.e., buried, shallow stream channels); therefore, the thickness of the silty clay loess stratum may vary across the site. Generalized cross sections depicting subsurface conditions across the northern and southern boundaries of the site are presented in Figures 4 and 5; the locations of the cross sections are shown in Figure 3.

2.1.2 Bedrock

Bedrock units beneath the loess consist of shale and limestone of Pennsylvanian and Mississippian age. The shale stratum is present beneath the loess in most areas across the site and, typically, the shale is weathered to a highly plastic residual clay. The shale and residual clay stratum thickness across the site ranges from 5 to 40 feet, generally thickening toward the east. The shale and residual clay is underlain by the St. Genevieve Limestone bedrock at depths ranging from 30 to 70 feet. The St. Genevieve Limestone is typically argillaceous (clayey), dense, with massive bedding and is estimated to be approximately 50 to 60 feet thick at the site. Limited information about the bedrock surface is available but the surface is believed to be irregular as illustrated in Figure 6. Regional and local bedrock dip is to the northeast at approximately 40 feet per mile, based on examination and correlation of regional well logs. Solution weathering has been documented regionally in the St. Genevieve Limestone and weathering is generally pronounced in the upper part of the unit. Fractures and joints are typical in the St. Genevieve, as observed in outcrops in the region. Joints and fractures in the bedrock beneath the site are likely to be infilled with the weathered shale, clays, and silts from overlying strata. The St. Genevieve Formation is underlain by the St. Louis Limestone, the Salem Limestone, and the Warsaw Formation, all of which are predominantly limestones.

2.1.3 Hydrological Units

Three separate hydrological units can be defined on the site with the information available to date. The upper silty clay unit (loess) is water

bearing and is underlain by the shale and residual clay, which make up a water-retarding unit. The limestone bedrock unit lies below the clay and shale. Limited hydrological information has been obtained on the limestone bedrock unit beneath the site. In the vicinity of the site, the ground water gradients in the upper portions of the limestone may be to the northwest toward Fee Fee Creek. Fee Fee Creek has eroded through the overlying Pennsylvanian Formations and may act as a local discharge point for Mississippian Formation waters. The general quality of the bedrock ground water is considered poor based on historical data on the limestone as a water source. Total dissolved solids (TDS) in the limestone formation increases with depth from the bedrock surface which makes this limestone unit unattractive as a potable water source. Due to the TDS problem and the low water yield potential of the unit, the public water supplies for the surrounding area are generally obtained from surface water sources.

The upper hydrological unit at the site (loess) has been more extensively characterized by site investigations. The lateral hydraulic conductivities measured in slug tests in this material range from 0.2 to 2.8 feet per day (1.0 x 10^{-3} to 3 x 10^{-5} cm/sec) with an average hydraulic conductivity estimated to be about 1 foot per day (3.4 x 10^{-4} cm/sec). The ground water gradient in this unit, based on water level measurements recorded at wells located throughout the site, is approximately 0.02 ft/ft or 110 feet/mile. The direction of gradient in the loess on site is approximately west-northwest as estimated from water table elevations in shallow monitoring wells. The observed ground water gradient is in agreement with the gradient direction inferred from the surface topography of the site and in adjacent areas. Figure 7 shows the February 1986 shallow water table contour surface at the site.

But not in agreement with bedrock topography

2.2 CONTAMINANT CHARACTERIZATION

2.2.1 History and Occurrence

During initial studies at the site to investigate the potential extent and distribution of contaminants, soil and ground water samples were analyzed for a wide array of organic pesticides and metals (see Table 1 for ground water

parameters). After the initial investigation, only analyses for those compounds which were identified or expected to be present at the site based on previous work were performed.

The analysis program implemented for routine ground water monitoring is listed in Table 2 and includes selected organo-chlorine pesticides, phenoxyacid herbicides, arsenic, and xylenes (xylol). Studies conducted in 1984 of the forty-two wells located within a 3-mile radious of the site showed most of the wells were drilled in the 1930's and 1940's. The wells are cased through the upper unconsolidated soils and are screened in the lower limestone units. The wells have operated at low flow rates (less than 10 gpm), and the water quality is at best fair to poor. A public drinking water source is now available to the well owners. Contaminants which have been detected in the ground water either regularly or occasionally are arsenic, lindane, aldrin, dieldrin, xylenes, 2,4-D, and 2,4,5-T. Present ground water contaminant concentrations are summarized in the sections below. Previous site investigations and ground water monitoring procedures and results are detailed in earlier reports which have been submitted to EPA. These include a report (#1) and supplement (#2) of hydrogeologic investigation and ground water evaluation dated October and December 1981 respectively, a report (#3) on ground water quality dated November 1982, and two ground water monitoring reports covering the periods July 1982 to May 1983 (#4) and July 1983 to January 1984 (#5). The analytical data obtained for ground water samples from these studies are summarized in the tables and appendices in this report. Ground water quality data are presented in Appendix A.

Is it used by all well owners?

2.2.2 Contaminant Distribution

2.2.2.1 Ground Water Contaminants in Shallow Bedrock

Data obtained from the sampling of wells OWC-12A, OWC-18, and OWC-20 were used to evaluate bedrock contamination. Concentration versus time plots (Appendix B) illustrate that aldrin, dieldrin, 2,4-D and 2,4,5-T concentrations in these deeply screened wells reached maximum levels during 1983. Arsenic and lindane levels appear to have remained fairly consistent over time. Xylenes

concentrations appear to have reached maximum levels in 1984 and began to decline in 1985. The xylenes peak in 1984 at OWC-12A may be associated with construction of a building addition in this area of the site during that period. ?
Generally, ground water contaminant concentrations from bedrock wells OWC-12A, OWC-18 and OWC-20 between May 1985, and February 1986, followed trends established from analyses of concentrations reported in previous samplings. Well OWC-12A continues to exhibit a wider range of contaminants at relatively higher concentrations than wells OWC-18 and OWC-20. Well OWC-20 continues to display non-detectable to low contaminant levels.

2.2.2.2 Ground Water Contaminants in Upper Sediments

Why not evaluate wells on south side or in middle of site?

Data obtained from the sampling of wells OWC-1, OWC-14, OWC-16, OWC-17, and OWC-19 were used in the evaluation of shallow site contamination. Four of the five shallow wells (OWC-14, OWC-16, OWC-17 and OWC-19) are located along the north boundary of the plant. The fifth well, OWC-1, is an upgradient well located on the south~~west~~ east corner of the site. The water quality of the upgradient well continues to be "clean" with nondetectible pesticides levels. Concentration versus time plots (Appendix B) indicate a 1984 maximum for xylenes in well OWC-17. This maximum corresponds with the maximum observed in the deeper monitoring wells located in the same area of the site. Aldrin, dieldrin, 2,4-D and 2,4,5-T concentrations remain relatively consistent over time at either trace or non-detectable levels in all shallow wells. Lindane levels are consistent per well but are elevated in wells OWC-17 and OWC-19, compared to the other shallow wells which exhibit trace to non-detectable levels. OWC-17 and OWC-19 lindane levels measured in 1985 and 1986 exceeded the NIPWDR Standard of 4.0 ug/l (Table A-1).

Arsenic concentrations in well OWC-19 are elevated in comparison to the other shallow wells but appear to be declining over the time period observed.

2.2.2.3 Contaminants in Shallow Surface Soil

During the initial site investigations performed in 1981, thirty-four soil borings were sampled for chemical analyses. These locations included samples

from the storm water retention pond sediments. The test results showed highest concentrations of arsenic to be in the north central area of the site in the vicinity of well OWC-11 and boring B-219. In these two locations, arsenic concentrations of 400 to 500 ug/g were detected in the top 1 to 2 feet of soil and then dropped to 3 to 5 ug/g at a depth of 10 feet.

WHAT ABOUT IN BETWEEN

Pesticides were detected in the soil samples taken from borings OWC-10 and OWC-11. These samples were taken at a depth of 5 feet in OWC-10 and from a depth of 2 feet in OWC-11. As with arsenic, higher concentrations were detected in the shallower sample (OWC-11) as compared to the deeper sample. Concentrations of approximately 100 ug/g aldrin, and 100 ug/g dieldrin, 570 ug/g arsenic, and 3 ug/g lindane were detected in samples.

In October, 1983, soil from the eastern and western portions of the site was sampled and analyzed for herbicides (2,4-D and 2,4,5-T), organo-chlorine pesticides, and arsenic. Herbicides were not detected above the detection limit of 0.1 ug/g. Arsenic was detected in samples from both the eastern portion (23-700 ug/g) and western portion (140 to 240 ug/g) of the site. Eight organo-chlorine pesticides were detected in six samples from the eastern portion of the site. Concentrations of aldrin ranged from not detected (.005 ug/g) to 1.69 ug/g, and lindane concentrations ranged from not detected (0.005 ug/g) to 0.446 ug/g. No 2,4,5-T was detected in any of the soil samples.

In July and August, 1985, shallow soil samples were obtained from the central railroad spur area (CHV locations on Figure 3) and analyzed for organo--phosphates, organo-halogens, and xylenes. The analytical results are presented on Table 7. The highest concentrations of 4,4'-DDD (440 ug/g), 4,4-DDE (100 ug/g), and 4,4-DDT (1230 ug/g) measured on site were found in the central section of the railroad spur. Chlordane concentrations ranging from 13 ug/g to 2100 ug/g were detected along the western portion of the spur. Toxaphene was detected at two of the six locations at levels of 500 ug/g and 5200 ug/g. Generally, the highest levels of soil contaminates were found in the upper 1 foot depth.

In February, 1985, soil samples from five locations (+ locations on Figure 3) were analyzed for 2,3,7,8-TCDD (dioxin). Concentrations in all samples were below the detection limit of 1 ppb.

3.0 POTENTIAL RECEPTORS INVESTIGATION

An investigation was made to identify potential receptors downgradient from the site where contact (dermal or oral) might occur in the event of off-site migration of contaminated surface or ground water. Two surveys have been conducted in order to assess potential ground water and surface water receptors. The 1981 site evaluation report (October 1981) included a survey of all water wells located within an area centered at the site and approximately three to four miles in radius. On March 20, 1986, a reconnaissance of the drainage on and around the site was conducted. The area surveyed included most of the Fee Fee Creek drainage basin in which the site is located. The results of these investigations are summarized below.

3.1 SURFACE WATER INVESTIGATION

3.1.1 Regional Surface Water Drainage Basin

The site is situated in the Fee Fee Creek watershed (Figure 8). Fee Fee Creek drains into the Missouri River which lies approximately 5 miles to the northwest of the site. This surface water basin drains an area of approximately 12 square miles and is bounded approximately by Olive Street Road to the south, I-270 to the west, Lackland Ave. and U.S. Highway 67 to the east, and the intersection of I-270 and the St. Louis and Southwestern (SL&SW) Railroad to the north. The area is highly developed (industrial, commercial, and residential), and local surface water runoff is controlled by railroads, highways, and man-altered drainage ways.

Surface water drainage on the site is generally to the west where it intersects a drainage ditch running north from Adie road. As interpreted from old aerial photographs, the original site drainage is generally similar, except that the north-south drainage of the creek originally transected the site further east

near the center of the site. The present day ditch drains into a 30-inch culvert near the northwest corner of the site which runs underground to Rock Island Court where it makes a 90 degree turn to the west running to the west side of Rock Island Road. The culvert runs north until it drains into a surface drainage ditch running along a railroad spur next to Fair Grove Ind. Road. This drainageway runs west until it drains into Fee Fee Creek at the intersection of Fee Fee Road and Fee Fee Creek. Although it had rained on March 19, 1986, very little water was observed on March 20, 1986 in the drainage ditches draining into Fee Fee Creek at the intersection of Fee Fee Road. Fee Fee Creek itself had flowing water as far south as Lackland Road which was the southern limit of the reconnaissance.

3.1.2 Upgradient Surface Water

Surface water runoff immediately upgradient of the site is diverted around the site by the drainage barriers of Adie Road and the railroad embankment to the east. Along Adie Road, east of the SL&SW Railroad, there is an old fertilizer factory which is referenced in the 1981 site evaluation report (October 1981). East-southeast of the site is an operating muncipal landfill which has been in existence for many years.

3.1.3 Downgradient Surface Water

It is unknown how many other industrial sources contribute runoff into the drainage system between the northwest corner of the site and the railroad spur ditch. Several potential downgradient contaminant sources were identified during the March 20, 1986 area surface drainage reconnaissance.

Approximately 2 miles downgradient from the site boundary, Fee Fee Creek crosses the SL&SW Railroad and passes within a few hundred yards of a residential area. The creek parallels the railroad tracks for a few hundred yards and then crosses under the tracks again. The creek bed adjacent to the residential area is low, appears to flood often, and contains a large amount of refuse (e.g., tires, trash, and dumped garbage). After crossing under the SL&SW Railroad to the

north again, Fee Fee Creek merges with the outflow from Creve Coeur Lake and then empties into the Missouri River.

Creve Coeur Lake, the associated recreational areas, and Creve Coeur Airport are all situated in the Missouri River alluvium upstream from the confluence of Fee Fee Creek and the Missouri River. This places them in a separate surface water drainage basin from Fee Fee Creek. There are no observable public access points to Fee Fee Creek.

3.2 GROUND WATER RECEPTORS INVESTIGATION

Surveys of water wells in the area surrounding the site were conducted in 1981 and 1984. A search was made in 1981 through the Missouri Geological Survey records and personal interviews were conducted in the immediate vicinity of the site. These investigations revealed six wells located within a 2-mile radius of the site and forty-two wells located within a 3-mile radius of the site. Of the six wells within 2 miles of the site, four are apparently abandoned. The remaining two were sampled and revealed no pesticide contamination. The locations of the nearest 34 wells are shown on Figure 9.

where are the two that were sampled?

4.0 SUMMARY

From analytical results, it appears that ground water entering the site from upgradient is relatively uncontaminated. On site, the area of highest concentrations of arsenic, xylenes, or pesticides in the ground water includes the central handling area and some of the northwestern portions of the site. The apparent lack of continuity in contaminant distribution between wells may indicate the presence of several sources of contaminants rather than a single source. From analyses of contaminant concentrations versus time plots, it appears that peak concentrations occurred in the years 1983 and 1984 and general improvements in the ground water quality at the site since that time are indicated.

ON SITE OR

why is it improving?

From the results of the site investigation and receptor evaluation, it appears that the on-site contamination does not pose an imminent or substantial threat

to human health. Additional investigations could be conducted to characterize the quality of groundwater immediately downgradient of the site where the potential for contamination exists.

TABLE 7
SOIL SAMPLE ANALYTICAL DATA SUMMARY
(concentrations are in ug/g)

Compound	CHV-S-01	CHV-S-02	CHV-S-03	CHV-S-04A	CHV-S-04B	CHV-S-05	CHV-S-06
4,4'-DDD	21.0	18.0	ND(2)	440.0	ND(2)	35.0	62.0
4,4'-DDE	10.0	6.0	ND(2)	26.0	ND(2)	7.0	27.0
4,4'-DDT	37.0	8.0	ND(2)	1230.0	75.0	134.0	140.0
Aldrin	5.0	2.0	ND(2)	52.0	42.0	5.0	15.0
Chlordane	200.0	1000.0	2100.0	ND(2)	ND(2)	ND(2)	ND(2)
Dieldrin	ND(2)	ND(2)	ND(2)	ND(2)	ND(2)	ND(2)	ND(2)
Heptachlor	5.0	6.0	180.0	ND(2)	ND(2)	ND(2)	ND(2)
Lindane	ND(2)	ND(2)	ND(2)	160.0	25.0	4.0	2.0
Toxaphene	ND(100)	ND(100)	ND(100)	ND(100)	500.0	ND(100)	ND(100)
Captan	ND(2)	ND(2)	ND(2)	ND(2)	ND(2)	16.0	ND(2)

Notes

1. Samples were taken on July 12, 1985.
2. All samples taken from 0 to 1 foot except CHV-S-04B which was taken from 1 to 2 feet.
3. ND indicates 'Not Detected' with the numbers in parenthesis denoting the detection limits.
4. The above table represents contaminants that were detected during this sampling period. See the Appendix for the analytic results for contaminants tested.

TABLE 7 (continued)
SOIL SAMPLE ANALYTICAL DATA SUMMARY
(concentrations in ug/g)

Compound	CHV-S-07			CHV-S-08		
	A	B	C	A	B	C
4,4'-DDD	14.0	ND(2)	ND(2)	56.0	ND(2)	14.0
4,4'-DDE	6.0	ND(2)	ND(2)	25.0	ND(2)	8.0
4,4'-DDT	ND(2)	ND(2)	ND(2)	370.0	ND(2)	71.0

GROUND WATER QUALITY DATA

TABLE A-1
SUMMARY OF GROUND WATER QUALITY DATA
CHEVRON CHEMICAL COMPANY, MARYLAND HEIGHTS, MISSOURI

Well No.	Range in Concentration Previously Reported	ARSENIC (mg/l) 13 Dec 84	14 May 85	15 Aug 85	16 Nov 85	17 Feb 86
Shallow						
OWC-1	.2 to 2.4	2.4	ND(1)	ND(1)	ND(1)	ND(1)
OWC-14	ND(1) to 8	1.3	3	2	4	2
OWC-16	ND(1) 14	1.4	1.	ND(1)	ND(1)	ND(1)
OWC-17	.76 to 21	21	3	ND(1)	NS	ND(1)
OWC-19	55.8 to 66.7	NS	NS	NS	NS	40
Deep						
OWC-12A	ND(1) to 19	9	3	3	ND(1)	ND(1)
OWC-18	4.1 to 30	5.9	5	1	9	5
OWC-20	12 to 63	8.9	6	6	5	11

Well No.	Range in Concentration Previously Reported	2,4-D (ug/l) 13 Dec 84	14 May 85	15 Aug 85	16 Nov 85	17 Feb 86
Shallow						
OWC-1	ND(.1) to 1.8	ND(1)	ND(1.0)	ND(1.0)	ND(1.0)	ND(1.0)
OWC-14	ND(1) to 50.9	ND(1)	ND(1.0)	ND(1.0)	ND(1.0)	ND(1.0)
OWC-16	ND(1) to 3.8	ND(1)	ND(1.0)	ND(1.0)	ND(1.0)	ND(1.0)
OWC-17	ND(.1) to 57	ND(1)	ND(1.0)	7.3	NS	ND(1.0)
OWC-19	ND(5.0)	NS	NS	NS	NS	ND(1.0)
Deep						
OWC-12A	ND(1) to 670*	113	23	16.1	22.4	ND(1.0)
OWC-18	ND(.1) to 1.1	ND(1)	ND(1.0)	ND(1.0)	ND(1.0)	ND(1.0)
OWC-20	ND(1) to 5.7	NS	ND(1.0)	ND(1.0)	ND(1.0)	ND(1.0)

Notes
ND ( ) - not detected and detection limit
NS - Not sampled
* - Indicated range of concentration is for well OWC-12
