Dear Mr. Nebu:

RE: FOURTH QUARTER GROUNDWATER MONITORING REPORT, ASSOCIATED PLATING COMPANY, 9636 ANN STREET SANTA FE SPRINGS, CALIFORNIA

WorleyParsons Komex is pleased to submit the attached Fourth Quarter 2006 Groundwater Monitoring Report for the Associated Plating Company (APC) located at 9636 Ann Street, in the city of Santa Fe Springs, California. This report presents the results obtained from the groundwater sampling conducted at the APC facility in November 2006. If you have any questions or comments, feel free to call at (714) 379-1157, extension 152.

Sincerely,
WorleyParsons Komex

1. INTRODUCTION

This document has been prepared by WorleyParsons Komex on behalf of the Associated Plating Company (APC). The report summarizes the groundwater sampling and well surveying conducted at 9636 Ann Street, Santa Fe Springs, California (herein referred to as the Site). The Site is located in Santa Fe Springs, California at an elevation of approximately 150 feet above mean sea level (MSL) with a local topographic gradient of less than 20 feet per mile to the southeast (**Figures 1 and 2**). Monitoring wells, MW-1 through MW-4, were installed at the Site on April 5 and 6, 2006 (**Table 1**) and were first sampled a week later (**Figure 3**).

Groundwater sampling and analysis completed at the Site during April 2006 identified the presence of chlorinated solvents and petroleum hydrocarbons.

The Department of Toxic Substances Control (DTSC), in their letter dated December 14, 2005 and in a meeting on August 22, 2006, requested that quarterly groundwater sampling be continued for one year. Therefore, fourth quarter groundwater sampling was conducted in November 2006 and is summarized in this report.

1.1 Geology and Hydrogeology

1.1.1 Regional Geology and Hydrogeology

Los Angeles County is underlain by the Los Angeles County Coastal Plain and is bounded by the Santa Monica Mountains to the north, the low lying Elysian, Repetto, Merced, and Puente Hills to the northeast, a political boundary coinciding with the boundary between Los Angeles County and Orange County to the southeast, and the Pacific Ocean to the southwest. Alluvial fans formed by the Los Angeles, Rio Hondo, and San Gabriel Rivers systems have coalesced to form the Downey Plain, which represents the largest area of recent alluvial deposition in the Coastal Plain. The Downey Plain is bordered by the La Brea, Montebello, and Santa Fe Spring Plains, and the Coyote hills to the north and northeast, the Newport Inglewood uplift to the southwest, and the Coastal Plain of Orange County to the southeast (DWR, 1961). The Downey Plain slopes gently to the south with an average gradient of less than 18 feet per mile. The Site is located between the Downey Plain and the Santa Fe Springs Plain. The Santa Fe Springs Plain is located south of Whittier and east of the San Gabriel River, in the area of the City of Santa Fe Springs. The Santa Fe Springs Plain is a low, slightly rolling topographic feature and represents a continuation of the Coyote Hills Uplift to the southeast.

The Coastal Plain of Los Angeles County is a deep groundwater reservoir filled by unconsolidated alluvial sands, gravels, clays, and silts. Fresh-water aquifers extend to depths of over 2,000 feet. The California Department of Water Resources (DWR) divided the coastal plain into four groundwater basins: the Santa Monica Basin, the West Coast Basin, the Hollywood Basin, and the Central Basin (DWR, 1961). The Site lies within the Central Basin, which is further divided into four parts for descriptive purposes: the Los Angeles Forebay Area, the Montebello Forebay Area, the Whittier Area, and the Central Basin Pressure Area.

The Site is located in the Central Basin Pressure Area. The Central Basin Pressure Area is called a "pressure area" because the aquifers within it are confined by aquicludes over most of the area. The major regional aquitards and aquifers beneath the Site occur in the Recent Alluvium, the Upper Pleistocene Lakewood Formation, and the Lower Pleistocene San Pedro Formation. Depth intervals for the major regional hydro-stratigraphic units (aquitards and aquifers) in the Site vicinity are presented in the table below:

Regional Hydro-stratigraphic Unit	Formation	Approximate Depth Intervals (feet below ground surface)
Bellflower Aquitard	Recent Alluvium	0 – 30
Gaspur	Recent Alluvium	30 – 65
Gage	Lakewood	65 – 110
Hollydale-Jefferson	San Pedro	110 - 130
Lynwood	San Pedro	130 – 210
Silverado	San Pedro	210 – 360
Sunnyside	San Pedro	360 - 610

1.1.2 Site Geology

The Site is underlain with artificial fill composed primarily of silt from the ground surface to an approximate depth of 7 feet below ground surface (bgs). At approximately 7 feet bgs a concrete pad is encountered, which is approximately four inches thick. Underlying the concrete pad is a silt and clay layer that extends to approximately 25 feet bgs. Below the silt and clay layer is a sand and gravelly

sand layer that extends to at least 48 feet bgs (**Figure 4**). Both the silt and clay layer and the sand and gravel layer correspond to the Recent Alluvium.

1.1.3 Site Hydrogeology

In April 2006, first groundwater was detected between 34 and 38 feet bgs (approximately 112 feet MSL) and corresponds to the Gaspur Aquifer. In August 2006, water levels ranged between 33 and 37 feet bgs. Since August, water levels have risen slightly to between 33.55 and 37.54 feet bgs in November 2006. Groundwater flow varies between the south-southwest and south-southeast at an approximate gradient of 0.001 feet per foot (ft/ft).

1.2 Site Conceptual Model

In accordance with the Site conceptual model developed below, the subsurface at the Site and Site vicinity was previously divided into three operable units: Operable Unit 1 (OU-1), Operable Unit 2 (OU-2), and Operable Unit 3 (OU-3) (**Figure 4**). OU-1 consists of fill material underlying the Site from ground surface to the top of the buried concrete pad (approximately 7 feet bgs). OU-2 consists of on-Site soils and the first groundwater zone, from the base of the concrete pad to approximately 50 feet bgs. OU-3 consists of the off-Site soils and the first groundwater zone.

Fill material in OU-1 is impacted by petroleum hydrocarbons (C7 to C36), fuel volatile organic compounds (VOCs), probably representing pre-existing contamination from the former storage tank, and chlorinated solvent compounds, consistent with releases of tetrachloroethene (PCE) from the APC facility.

2. GROUNDWATER SAMPLING

2.1 Groundwater Gauging and Sampling Procedures

Well construction details for the four groundwater monitoring wells (MW-1 through MW-4) are included in **Table 1.** On November 13, 2006, the four monitoring wells were gauged and then purged and sampled. Following gauging, the wells were purged of at least three well volumes of water, allowed to recover, and then sampled using an electric pump. Groundwater gauging and sampling field notes are provided in **Appendix A.**

2.2 Waste Disposal

Waste generated as part of this investigation included purged groundwater and decontamination water used during sampling. Water was contained in one Department of Transportation (DOT) approved 55-gallon drum and temporarily stored at the Site prior to disposal. Groundwater and decontamination water were removed from the Site and transported to a suitable off-Site disposal facility by a licensed non-hazardous waste hauler. The waste manifest is provided in **Appendix B.**

2.3 Quality Assurance/Quality Control Sampling

Field quality assurance/quality control (QA/QC) samples were collected on November 13, 2006, during groundwater sampling activities. An equipment rinsate blank was collected from the groundwater electric pump by running distilled water through the pump hose into three 40-milliliter (ml) volatile organic analysis (VOA) vials and one 1 liter (L) amber glass container. A field blank was collected by filling three 40 ml VOA vials and one 1 L amber glass container with distilled water, leaving them exposed to ambient air during collection of the equipment blank, and then sealing them. A trip blank, consisting of one sealed 40 ml VOA vial filled with distilled water, was obtained from the laboratory and kept in the ice-chest throughout the day to evaluate if there was any introduction of VOCs during storage and transportation.

2.4 Laboratory Analyses

Monitoring well groundwater samples and QA/QC samples were labeled, placed in an ice chest, and delivered under chain-of-custody (COC) to Sierra Analytical Inc. of Laguna Hills, California, within 24 hours of collection. The samples were analyzed for the following:

- Total petroleum hydrocarbons (TPH), ranging from C7 to C36, in accordance with USEPA Method 8015B; and
- VOCs in accordance with USEPA Method 8260B.

3. GROUNDWATER RESULTS

3.1 Groundwater Results

Groundwater depths in the four monitoring wells ranged from 33.55 to 37.54 feet bgs (**Table 2**). During this sampling event, groundwater flow was generally towards the south-southwest at a gradient of 0.001 ft/ft (**Figure 5**).

A sheen of light non-aqueous phase liquid (LNAPL) was observed on the product level probe in three of the wells: MW-1, MW-2, and MW-4. Well MW-3 had an observed LNAPL layer of .01 inches.

Groundwater gauging and laboratory analytical results are provided in **Tables 2, 3 and 4**, respectively. The complete laboratory report, including COC and laboratory QA/QC analyses, is provided in **Appendix C**.

Petroleum hydrocarbons were detected in groundwater collected from the four monitoring wells: MW-1, MW-2, MW-3, and MW-4 at concentrations slightly less than the previously recorded August concentrations (**Table 3**). The maximum concentration of TPH decreased from 16 milligrams per liter (mg/L) in August to 3.8 mg/L in well MW-1. The minimum TPH concentration also decreased, from 2.1 mg/L in well MW-3 to 1.0 mg/L in well MW-2. The lateral distribution of TPH in groundwater for this sampling event is depicted in **Figure 6**.

VOC groundwater results are presented in **Table 4**. Chlorinated solvents were detected in every well (**Figure 7**). Since August 2006, chlorinated solvent concentrations in groundwater collected from wells MW-1 through MW-4 have remained fairly constant. Vinyl chloride (VC) was detected in groundwater collected from all four wells; however, the concentrations have slightly decreased since August. PCE was detected in groundwater at 3.6 micrograms per liter (ug/L) in well MW-4. Trichloroethene (TCE) was detected in groundwater collected from well MW-1 at 28 ug/L. Cis-1, 2-dichloroethene (cis-1,2-DCE) was detected in groundwater for the first time at a concentration of 1.2 ug/L in well MW-4.

3.2 QA/QC Analytical Results

The results of QA/QC sample analyses are provided in **Table 5**. Groundwater laboratory QA/QC samples for TPH and chlorinated solvents were generally within acceptable levels. A review of the laboratory analytical report indicates that all internal laboratory QA/QC calibration checks, matrix spike,

and matrix spike duplicate recoveries were within acceptable ranges (**Appendix C**). Chlorinated solvents were not detected in the equipment rinsate blank, field blank or trip blank. However, toluene and TPH were detected in the equipment blank at concentrations of 11 ug/L and 0.32 mg/L, respectively. During this sampling event, the equipment blank was collected from the sampling pump hose. The pump hose was cleaned before sampling and between each well by pumping it with water from a three bucket decon rinse system: the first bucket contained distilled water and a non-phosphate detergent, and the second and third bucket contained tap water only. Due to the presence of LNAPL in the four monitoring wells, standard three bucket rinse decontamination procedures appear unable to entirely remove low levels of fuel related compounds. Groundwater results are deemed acceptable for the following reasons: standard decontamination practices were followed, chlorinated solvents are the primary contaminants of concern, and they were not detected in any of the sampling blanks.

4. CONCLUSIONS AND RECOMMENDATIONS

4.1 Conclusions

In November 2006, groundwater flow beneath the Site was towards the south-southwest at a gradient of 0.001 ft/ft and depth to groundwater ranged from to 33.55 to 37.54 feet bgs (113.23 to 113.38 feet MSL).

In November 2006, the TPH and chlorinated solvent concentrations detected in groundwater beneath the Site remained fairly constant. However, concentrations of TPH and VC detected in groundwater beneath the Site have slightly decreased.

4.2 Recommendations

In accordance with the DTSC's request, two additional quarterly groundwater sampling events should be conducted to analyze the contaminant trends.

5. CLOSURE

We trust that this report satisfies your current requirements and provides suitable documentation for your records. If you have any questions or require further details, please contact the undersigned at any time.

Notes:

1) VOC = volatile organic compounds analyzed using EPA Method 8260B

2) ug/L = micrograms per liter

3) <1.0 = compound not detected at or above the indicated laboratory reporting limit

4) -- = not analyzed

5) Bold type indicates compound was detected.

Notes:

1) TPH = total petroleum hydrocarbons (carbon range) analyzed using EPA Method 8015B
2) VOCs = volatile organic compounds analyzed using EPA Method 8260B
3) mg/L = milligrams per liter
4) ug/L = micrograms per liter
5) <1.0 = compound not detected at or above the indicated laboratory reporting limit
6) Bold type indicates compound was detected.
7) -- = not analyzed
