1 Introduction

This human health risk assessment (HHRA) is an Appendix to the Toxic Substances Control Act (TSCA) Work Plan for a portion of the Boston Convention & Exhibition Center (BCEC) Project site located in Boston, Massachusetts. The TSCA Work Plan was prepared in support of a Risk-based Disposal Approval request for polychlorinated biphenyls (PCBs), as specified in 40 CFR 761.61(c). The objective of this HHRA is to provide a quantitative estimate of the risk posed to humans through potential exposure to PCB-contaminated soil at the TSCA Site under future land use conditions which consider remediation of the TSCA Site. The results of the HHRA are used to support the proposed cleanup remedy for the site.

1.1 SITE DESCRIPTION

The Boston Convention & Exhibition Center (BCEC) consists of two separate parcels, Phase 1 and Phase 2. Construction within Phase 1 of the BCEC is complete and included the current BCEC building, located at the intersection of Summer Street and D Street in South Boston. Recent plans for redevelopment of Phase 2 of the BCEC included an expansion of the existing Convention Center building which would cover the majority of Phase 2. It is now clear that the expansion of the BCEC will not occur in the near future, and that the current and future foreseeable use of the BCEC Phase 2 area is a controlled access parking lot. This HHRA applies to a portion of the Phase 2 area, west of the former C Street (referred to herein as the "TSCA Site"), and is shown on Figures 2 and 4 of the accompanying TSCA Work Plan.

The TSCA Site currently consists of a portion of the BCEC parking lot located southwest of the current BCEC building. The limits of the TSCA Site are within the Phase 2 area and are generally bounded by New Cypher Street to the southwest, a portion of the BCEC Phase 2 parking lot to the southeast (starting around the former C Street location), railroad right-of-way adjacent to the South Boston Bypass Haul Road to the northwest (Parcel 20B), and an access roadway to the northeast (beyond which is the existing BCEC building). The limits of the TSCA Site are shown of Figure 4 of the accompanying TSCA Work Plan.

1.2 HISTORICAL SITE USE

The BCEC project site is comprised of several parcels that have been used for industrial and commercial purposes for over 100 years. Such uses included railway lines and freight storage, stockyard, machine shops, and scrap metal storage. Further details of historical site uses are provided in the accompanying TSCA Work Plan.

From 1947 to 1985, a portion of the TSCA Site owned by Louis Freedman was operated as The Boston Junk Company. SAK Recycling Corporation bought this portion of the TSCA Site (referred to herein as the SAK property) in 1992, and continued operating the junkyard until 1996, when it was ordered by the Massachusetts Department of Environmental Protection (MassDEP) to cease activities.

Although specific releases at the SAK property were not documented by SAK Recycling Corporation or prior owners of the property, records of various incidents were recorded by previous consultants and regulators dating back to 1982. Incidents were reported to have included storage of transformers, disassembly of transformers by blowtorch, leaking transformers, and on-site fires. A series of investigations conducted by environmental consultants at the SAK property detected the presence of total petroleum hydrocarbons (TPH), PCBs, and metals in soils.

1.3 HISTORICAL RESPONSE ACTIONS

Several response actions have been conducted at the TSCA Site (i.e., the Phase 2 area, west of the former C Street, which includes the SAK property) as part of construction and/or remediation activities, including the indirect thermal desorption treatment and off-site removal of approximately 3,500 cy of soil/debris from the SAK property in the early 2000s. Following off-site disposal of the soil and debris, a protective asphalt cap (referred to as the EM-1 Cap) was built on the SAK property as a temporary installation by the Boston Redevelopment Authority, to provide a paved surface for construction laydown and to eliminate potential exposure to underlying oil and hazardous materials in soil. The extent of the EM-1 Cap is shown on Figure 4 of the TSCA Work Plan. Further details of response actions conducted at the TSCA Site are provided in the accompanying TSCA Work Plan.

1.4 CURRENT SUBSURFACE CONDITIONS

The Phase 2 area (both east and west of the former C Street) was used as a temporary soil staging area during construction of the existing BCEC building. Approximately 250,000 cy of Fill material excavated from Phase 1 was temporarily stockpiled above the EM-1 Cap. The majority of the Phase 1 Fill that was stockpiled in the Phase 2 area was characterized and removed during construction of the BCEC. However, approximately 25,000 cy of Phase 1 Fill material was retained (i.e., not disposed of) in order to raise the grade of the Phase 2 area to create the existing parking lot in the Phase 2 area (hereafter this Fill material is referred to as "Parking Area Backfill".) Thus, current stratigraphy at the TSCA Site generally consists of the following layers (not all layers were encountered at each boring, and the EM-1 Cap does not extend across the entire TSCA Site):

- Bituminous pavement (i.e., the current parking lot surface; comprised of 3.5 inches of bituminous pavement)
- Parking Area Backfill (ranging in thickness from approximately 6 inches in the eastern portion of the Site to more than 3 feet in the central and western portion of the Site)
- EM-1 Cap (comprised of 6 inches of bituminous pavement)
- Historic Urban Fill
- Hydraulic Fill
- Organic Deposits
- Marine Deposits
- Glacial Deposits
- Bedrock

A description of these strata is provided in the TSCA Work Plan. Subsurface soil profiles were generated based on subsurface explorations performed by Haley & Aldrich between 2010 and 2015. The subsurface exploration locations are shown on the figures in the accompanying TSCA Work Plan.

1.5 SITE REDEVELOPMENT AND REMEDIATION

Initially, redevelopment plans for the BCEC Phase 2 area consisted of construction and expansion of the existing Convention & Exhibition Center building over the Phase 2 area, including a portion of the TSCA Site. However, expansion of the BCEC building has been indefinitely postponed. Therefore, the Phase 2 area will remain a controlled access parking lot that serves the BCEC for the foreseeable future.

Consequently, remediation of the TSCA Site and restoration of the parking lot in the Phase 2 area is proposed.

Remediation of the TSCA Site, which will occur within the limits of the TSCA-regulated area, involves excavation and off-site removal of Hot Spots (as defined in the Massachusetts Contingency Plan) and soils containing concentrations of PCBs greater than or equal to 500 mg/kg. A summary of the remedial approach and sequencing are provided below and details are provided in the TSCA Work Plan.

1. Strip asphalt from the existing parking lot surface to expose the Parking Area Backfill that was placed over the EM-1 Cap and former ground surface in 2005.
2. Excavate and temporarily stockpile Parking Area Backfill (on site) to expose the EM-1 Cap and former ground surface in areas where excavation will occur to remove Hot Spots and soil with PCB concentrations greater than or equal to 500 mg/kg.
3. Excavate through the EM-1 Cap and below the EM-1 Cap or former ground surface for those areas outside of the EM-1 Cap (conservatively assumed to be El. 17) to remove Hot Spots and soil containing PCB concentrations greater than or equal to 500 mg/kg and dispose of the soil and asphalt (generated from EM-1 Cap removal) off-site (Figure 13 in TSCA Work plan).
4. Place a marker layer over the excavation and backfill the excavation with Parking Area Backfill and imported soils to the bottom of the existing EM-1 Cap or to the subgrade elevation for areas outside the EM-1 Cap.
5. Place a 6-in thick asphalt cap above the backfill material within the limits of the existing EM-1 Cap, followed by additional backfill to achieve the subgrade elevation within the EM-1 Cap area.
6. Restore the TSCA Site to its previously existing condition (paved parking lot with 6 inches of dense graded crushed stone and 3.5 inches of asphalt, or a rip rap drainage area).

At the completion of Step 6 (above), the TSCA Site will be remediated and returned to use as a controlled access parking lot.

1.6 ORGANIZATION OF RISK ASSESSMENT REPORT

The HHRA consists of the following major components:

- Data Evaluation
- Exposure Assessment;
- Toxicity Assessment;
- Risk Characterization, and
- Uncertainty Analysis.

Section 2, Data Evaluation, reviews the analytical data collected at the TSCA Site and provides the rationale for the subset of analytical data and specific data sets that are used in the risk assessment. This section also provides the methods used to statistically summarize and present analytical data.

Section 3, the Exposure Assessment, provides information documenting the human populations that could access or use the TSCA Site under current and possible future land use conditions, discusses how those populations could potentially be exposed to the PCBs in TSCA Site media, and quantifies how much exposure could occur. Specific components of the Exposure Assessment include descriptions of current and future land uses, sources of contamination and exposure media, exposure pathways, and exposure scenarios, and documentation of exposure point concentration (EPC) and exposure intake calculations.

Section 4, Toxicity Assessment, discusses the chemical-specific toxicity criteria for COPCs that are used to quantify the potential human risks. Section 5, Risk Characterization, provides the methods for calculating the noncarcinogenic and carcinogenic risks for each receptor and provides a summary of the results of the risk evaluations. Any qualitative evaluations of risk are also presented in the risk characterization. Section 5 also includes an Uncertainty Analysis, which presents a discussion of both the inherent and site-specific uncertainties associated with the risk assessment. Section 6, Summary and Conclusions, presents a discussion of results of the risk assessment.

Appendices to this report provide supporting documentation for EPC and risk calculations.

1.7 APPLICABLE GUIDANCE

The HHRA was performed following standard United States Environmental Protection Agency (EPA) guidelines including the following documents:

- *Risk Assessment Guidance for Superfund (RAGS)*, *Volume I, Part A* (EPA, 1989);
- *RAGS, Volume I, Part E, Dermal Risk Assessment* (EPA, 2004)
- *RAGS, Volume I, Part F, Inhalation Risk Assessment* (EPA, 2009)
- *Standard Default Exposure Factors* (EPA, 2014)
- *Exposure Factors Handbook* (EPA, 2011)
- *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (EPA, 2002a)

A complete list of references is presented in the references section.

2 Data Evaluation

The data evaluation identifies the available data and documents the selection or exclusion of particular data for use in the risk assessment, provides the rationale for the way data will be grouped for evaluation in the risk assessment, and documents the methods used to summarize data using statistical descriptors.

2.1 DATA SOURCES AND DATA QUALITY

The Risk Assessment for the TSCA Site is based on data collected by Haley & Aldrich during four extensive subsurface exploration programs conducted at the TSCA Site between 2010 and 2015. Historic data was not used given that lack of horizontal or vertical controls of those sampling programs. The quality of data collected during investigations is acceptable for use in risk assessment as described below.

Data were selected for use in the HHRA using the criteria established by USEPA in "Guidance for Data Usability in Risk Assessment" (USEPA, 1992). The data are a product of sample collection and handling, laboratory analyses, and data Quality Assurance/Quality Control (QA/QC) procedures performed in accordance with USEPA methods. The following bullets provide a brief summary of the types of samples that were collected by Haley & Aldrich:

- Surface and subsurface soil samples were collected from direct push borings (e.g., Geoprobe™ or equivalent), and drilled borings. Soil samples were generally collected as two-foot composites (e.g., 0 – 2 ft bgs, 2 – 4 ft bgs). However, some borings were sampled over a larger interval (e.g., 0 – 4 ft bgs). In addition, some borings were sampled over smaller intervals (e.g., 0 – 1 ft bgs) to refine delineation of the nature and extent of PCBs.
- Groundwater samples were collected using low-flow sampling techniques from monitoring wells. Haley & Aldrich began groundwater sampling for PCBs as part of a Maintenance and Monitoring plan in April 2004 and has conducted sampling on a biannual basis from April 2004 through May 2016. Haley & Aldrich also collected two rounds of groundwater sampling in 2010 and 2011 for various other constituents.

2.1.1 Chemical Analyses

Samples collected from media at the TSCA Site were analyzed using the following analytical methods:

- Volatile Organic Compounds (VOCs): Method 8260B
- Semi-Volatile Organic Compounds (SVOCs): Method 8270C
- Total Petroleum Hydrocarbon (TPH)
- Extractable and Volatile Petroleum Hydrocarbons
- PCBs: Method 8082 using soxhlet extraction
- Metals: Method 6010

2.1.2 Data Quality

The samples selected for use in the HHRA have undergone data validation or review. A representativeness evaluation and data usability assessment (REDUA) was performed for the data collected from the 2010/2011 subsurface investigation program and included the Class C-2 RAO

Statement, dated 29 June 2012, for RTN 3-16211. In summary, data from the 2010/2011 subsurface investigation program are of appropriate quality for incorporation into this TSCA Work Plan.

The data collected from the 2015 subsurface investigation programs were also reviewed in consideration of the National Functional Guidelines and MassDEPs Policy #WSC07-350 "Guidance "MCP Representativeness Evaluations and Data Usability Assessments". Some of the data were qualified and the QC non-conformances are detailed in Attachment G.

Quality control limits for two samples from the 2015 subsurface investigation program were beyond data quality assessment control limit criteria described in Appendix IV of MassDEP Policy #07-350. A brief discussion of each sample follow:

- 2,4,6 tribromophenol surrogate recovery was below 10% in sample M14A_S1_2-7.5. This surrogate is associated with acid extractable compounds only and other acid extractable surrogate recoveries in this sample were acceptable. Since acid extractable compounds are not principal contaminants of concern at the TSCA Site, the results for sample M14A_S1_2-7.5 are accepted without further qualification and are suitable for the intended use.

- A Field Matrix Spike of sample C15a_S1_5.0-9.0 indicated total lead matrix spike duplicate recovery outside recommended limits due to high lead concentration in the native sample. Total lead recoveries were acceptable in the matrix spike for this and other project samples. Therefore, the results for sample C15a_S1_5.0-9.0 are accepted without further qualification and are acceptable for the intended use.

In summary, no data were rejected and the data set is therefore suitably appropriate for incorporation into this TSCA Work Plan.

2.2 EXTENT OF TSCA REGULATED SOIL

As currently understood, the horizontal limits of the TSCA-regulated soil are defined by PCBs that are present at concentrations greater than or equal to 1 mg/kg within the former Boston Junk/SAK Site and a portion of the adjacent former Energy International property and are shown on Figure 4 of the TSCA Work Plan. The TSCA Site includes a strip of New Cypher Street.

The vertical limits of the TSCA-regulated soil are defined as soil with PCB concentrations greater than or equal to 1 mg/kg below the ground surface that existed at the completion of the EM-1 Cap (either at the bottom of the EM-1 Cap or El. 17 in areas where the EM-1 Cap is no present). The most elevated concentrations of PCBs were detected in the Historic Urban Fill material at the central and southern portions of the TSCA Site, below the EM-1 Cap area, from the former ground surface to approximate El. 8 (approximately 0 to 14 ft bgs, currently). Lesser concentrations of PCBs were detected in the Hydraulic Fill and Organic Deposits.

2.3 OTHER SOIL

The Parking Area Backfill that was removed from the Phase 1 area and placed at the TSCA Site contains very low levels of PCBs (where detected, at generally less than 10 mg/kg) that, in our opinion, were not due to a TSCA release and are therefore not regulated under TSCA. As described in the accompanying Work Plan, the PCBs detected in the Parking Areas Backfill are consistent with PCBs detected in Urban

Fill material in Phase 1 of the BCEC and within several other properties in this area of South Boston, none of which were subject to regulation under TSCA.

VOCs, SVOCs, metals, and petroleum compounds were detected in Parking Area Backfill soil and soils that are regulated under TSCA. These constituents are not regulated under TSCA, but are instead regulated under the Massachusetts Contingency Plan (MCP) at 310 CMR 40.0000. Although these constituents are included in this HHRA to provide an estimate of total cumulative health risk, they must ultimately be shown to meet a Condition of No Significant Risk as defined in 310 CMR 40.0900 to achieve regulatory closure under the MCP.

2.4 DATA USED IN HHRA

The following data sets are compiled for use in the HHRA. Samples included in each of the data sets, as well as the analytical data for the samples, are identified in Attachment A. Soil sample locations are shown on Figure 4 of the TSCA Work Plan.

2.4.1 Soil

Soil data are used in the HHRA to evaluate potential direct contact (incidental ingestion and dermal contact) and inhalation (particulate and vapor) risks that may occur if people were to contact soil under the proposed re-use conditions. The soil data includes 2,427 PCB soil samples collected between 2010 and 2015 by Haley & Aldrich. Soil samples were segregated into the following data sets:

1. Parking Area Backfill: samples collected from above the EM-1 Cap or above former ground surface (El. 17) in areas outside of the EM-1 Cap.
2. Surface soil (0 – 2 ft bgs): samples collected from depths within two feet of the ground surface. Samples that were collected from depths that straddle the 2 ft bgs interval were conservatively included in the 0 – 2 ft bgs data set. Samples that are within two feet of the ground surface but were collected from depth beneath the EM-1 Cap were not included in the 0 – 2 ft bgs data set because the presence of the EM-1 Cap eliminates potential exposure to soils beneath the Cap.
3. New Cypher Street: samples collected from 0-15 feet below ground surface (ft bgs) from sampling grid columns A and B.
4. Soil Beneath EM-1 Cap: samples collected from locations within the footprint of the EM-1 Cap and at elevations below the EM-1 Cap. Samples that were collected form grids located both within and outside of the EM-1 Cap were assigned to the EM-1 Cap data set if 75% or more of the grid was located beneath the Cap.
5. Soil Outside of the EM-1 Cap: samples collected from below El. 17 in grids located outside of the EM-1 Cap.

2.4.2 Data Not Used in HHRA

Soil data that are not used in this HHRA include:

- Soil containing PCBs greater than 500 ppm that will be removed as part of remediation.
- Data from soil samples collected outside the TSCA-regulated area.
- Five samples that will be removed as part of remediation which are considered to be Hot Spots under the MCP (310 CMR 40.0006) and have exposure point concentrations of antimony, lead, and/or PCBs greater than MCP Upper Concentration Limits (310 CMR 40.0996).

The soil samples with constituents present at concentrations greater than MCP Upper Concentration Limits must be remediated in order to achieve regulatory closure under the MCP. This HHRA is based on the understanding that samples associated with the conditions listed in the bullets above will be remediated and will therefore not be representative of post-remedial TSCA Site conditions. Soil samples that will be remediated are shown in Figure 13 of the TSCA Work plan. Post-remedial PCB concentrations are shown in Figure 14 of the TSCA Work plan.

In addition, groundwater has been evaluated in samples collected by Haley & Aldrich from 2004 through 2016. As described further in the TSCA Work Plan, the results of groundwater sampling indicate that PCBs are not present in the dissolved state in groundwater, and that PCBs are not migrating via groundwater flow. As such, groundwater data were not further evaluated in this HHRA.

2.5 DATA SUMMARIZATION METHODS

The analytical data for each data set that was developed in support of the HHRA was summarized into descriptors which identify:

- Frequency of detection (number of positively detected results/total number of results)
- Range of detected concentrations
- Average of all samples, including detected results and ½ the reporting limit for those samples for which a constituent was non-detect.

The following procedures were applied when summarizing the analytical data for the HHRA:

- For samples in which both an original and a field duplicate result are available, both results are used.
- For samples in which analyte concentrations are detected outside the calibration range, and the samples are diluted and reanalyzed, data with the highest detected concentrations were used in the risk assessment.

Total PCB concentrations were calculated using analytical data for Aroclors, as follows:

- For soil samples in which only some Aroclors were detected, total PCBs were summed as the detected Aroclor values plus ½ the reporting limit for Aroclors that were not detected.
- For soil samples in which no Aroclors were detected, the total PCB concentration used in the data set was ½ the highest reporting limit among all Aroclors.

2.6 CHEMICALS OF POTENTIAL CONCERN

COPCs are chemicals that may pose more than a *de minimis* health risk. The primary COPC for the TSCA Site is PCBs, and PCBs are the only TSCA-regulated substance evaluated in this HHRA. However, in order to evaluate cumulative risks associated with potential exposures to multiple chemicals (i.e., TSCA-regulated PCBs and other non-TSCA regulated chemicals), a COPC selection was performed for all detected chemicals within each of the soil data sets.

The COPC selection is performed by using a concentration-toxicity screening to reduce the number of chemicals evaluated in the risk assessment to only those that would potentially pose more than a *de minimis* health risk (USEPA, 1989). The procedure used to select COPCs for the HHRA is summarized as follows, and is consistent with USEPA methodology (USEPA, 1995):

A. Comparison to Available Criteria:

- Selected as a COPC in soil if the maximum detected concentration exceeds the USEPA Regional Screening Level (RSL) for industrial soils (USEPA, 2016a).

The RSLs are protective for direct contact (ingestion and dermal contact) exposures, as well as for inhalation of constituents that may be released to air. The RSLs are derived for a 1 in 1 million ($1x10^{-6}$) cancer risk level or a non-cancer hazard quotient (HQ) of 1. Per USEPA Region 1 guidance (USEPA, 1995), the RSLs based on non-carcinogenic effects are adjusted to represent a HQ of 0.1 for the purposes of COPC selection. The use of industrial soil RSLs to select COPCs represents a conservative approach since uses of the TSCA Site will be non-residential, the majority of soil will be covered by hardscapes, and contact with soil will generally not occur. This approach results in selection of some chemicals as COPCs for soil that, under the site-specific exposure conditions, will be associated with less than a *de minimis* risk.

B. Low Frequency of Detection:

- Despite other criteria, an analyte is not selected as a COPC if the frequency of detection is 5 percent or less (USEPA, 1989).

The results of the COPC selection for each data set are provided in Tables D-1 through D-5. The following notes are used to denote the reasons for selection or exclusion of analytes as COPCs:

ASL: Above Screening Level - The concentration used for COPC screening (the maximum detected concentration) is greater than the RSL; the analyte is therefore selected as a COPC.

BSL: Below Screening Level - The concentration used for COPC screening (the maximum detected concentration) is less than the RSL; the analyte is therefore not selected as a COPC.

NSL: No Screening Level - There is no screening value available; the analyte is therefore selected as a COPC.

FOD: Frequency of Detection - The frequency of detection is below 5%; the analyte is therefore not selected as a COPC.

COPCs selected in soil generally include PCBs, PAHs, antimony, arsenic, lead, thallium, and petroleum hydrocarbons. In data sets for soils beneath the EM-1 Cap and outside of the EM-1 Cap, additional COPCs include chlorinated benzenes, benzene, and mercury.

3 EXPOSURE ASSESSMENT

The exposure assessment is conducted to evaluate the populations of humans that may potentially use or access the TSCA Site under the current and possible future land use conditions, the mechanisms or exposure pathways by which those humans may be potentially exposed to COPCs at the TSCA Site, and the magnitude of exposure that may occur through the potential exposure pathways. This process involves three steps:

1. Characterization of the exposure setting in terms of physical characteristics, current and future uses of the TSCA Site, and the populations that may be potentially exposed to COPCs under the current and possible future land uses;

2. Identification of potential exposure pathways and exposure points to which the populations may be exposed; and

3. Quantification of exposure for each population from all exposure pathways. Exposures are quantified by developing receptor exposure scenarios, identifying EPCs, and then calculating chemical intakes.

These components are provided in the sections below.

3.1 CHARACTERIZATION OF THE PHYSICAL SETTING

The TSCA Site is located in an urban area of South Boston and currently consists of a portion of the BCEC parking lot located southwest of the current BCEC building. The limits of the TSCA Site are within the Phase 2 area and are generally bounded by New Cypher Street to the southwest, a portion of the BCEC Phase 2 parking lot to the southeast (starting around the former C Street location), railroad right-of-way adjacent to the South Boston Bypass Haul Road to the northwest (Parcel 20B), and an access roadway to the northeast (beyond which is the existing BCEC building). The majority of the TSCA site is paved (e.g., where the parking lot is located). Portions of the TSCA Site located near the South Boston Bypass Haul Road and Cypher Street are unpaved. Future use of the TSCA Site will be as a paved parking lot to support the Convention & Exhibition Center. The area surrounding the TSCA Site is characterized as primarily commercial, with some industrial and residential use.

3.2 IDENTIFICATION OF RECEPTORS AND POTENTIAL EXPOSURE PATHWAYS

3.2.1 Receptors

Current receptors at the TSCA Site include BCEC workers and visitors who use the parking lot. In addition, it is possible that trespassers access the parking lot during off-hours. Future receptors at the TSCA Site include the same receptors as those associated with current use, plus construction workers who may be engaged in parking lot maintenance, repair, and repaving, and construction and utility workers who may perform improvements and maintenance of Cypher Street. Deed restrictions will be placed on the TSCA Site to prevent use for residential, school, day care, and outdoor active recreational uses (e.g., sports playing fields). In addition, the deed restriction will require soil management and health and safety plans to be followed during any excavation of soil beneath the EM-1 Cap or beneath EL 17 at locations outside of the Cap; replacement of the EM-1 Cap will also be required.

3.2.2 Potential Exposure Pathways

An exposure pathway describes the course a chemical takes from the source to the exposed individual. Exposure pathway analysis links the sources, locations, and types of environmental releases with population locations and activity patterns to determine the significant pathways of human exposure. Exposure pathways generally consist of four elements:

(1) a source and mechanism of chemical release,
(2) a retention or transport medium,
(3) a point of potential human contact with the contaminated medium (known as the exposure point), and
(4) an exposure route at the contact point (e.g., ingestion of soil, inhalation of vapors) (USEPA, 1989).

In order for the exposure pathway to be considered potentially complete, all four elements must be present. Elimination of exposure pathways may occur based on site-specific conditions, for example if the probability of exposure occurring is low or if the impact of the exposure pathway is expected to be minor in comparison to other exposure pathways (EPA, 1989). Exposure pathways may also be made incomplete through use of institutional or engineering controls, for example by applying deed restrictions which prevent certain property uses from occurring, or requiring that a ground cover (such as a soil cap or concrete) remain in place. Potentially complete exposure pathways at the TSCA Site are listed below.

3.2.2.1 *Current Use*

The TSCA Site is currently used as a parking lot and a portion of a public roadway (Cypher Street). The TSCA Site has minimal exposure potential to human receptors because the TSCA Site is covered by at least 3.5 inches of bituminous pavement over six inches of dense graded stone, six inches of crushed stone over filter fabric, or 18 inches of rip rap over filter fabric. Visitors and trespassers would be expected to access the TSCA Site but would not be exposed to TSCA Site soils due to the presence of pavement or stone over TSCA Site soil.

3.2.2.2 *Future Use*

Future planned development of the TSCA Site will include continued use as a parking lot to support the Convention Center, and a public roadway (Cypher Street). Several future use scenarios were evaluated to demonstrate that the planned remediation of the TSCA Site will ensure that health risks are acceptable for these uses.

3.2.2.3 *Exposure Routes*

There are three exposure routes by which humans can be exposed to COPCs in soil. The exposure routes include ingestion, dermal contact, and inhalation. More than one exposure route may be applicable to each of the exposure media evaluated in the HHRA.

Ingestion. Ingestion exposures occur when substances are swallowed. When an environmental medium such as soil that contains COPCs is swallowed, the chemicals can be absorbed into the blood stream from the gastrointestinal tract and/or directly interact with tissues within the gastrointestinal tract. Most ingestion exposures to environmental media are incidental in nature, meaning that they are non-

intentional. For example, soil can be incidentally ingested if it is touched and adheres to the hand, and the hand (fingers) is then placed into the mouth, where the soil can be transferred to the mouth and swallowed.

Dermal Contact. Dermal exposures occur when a substance is absorbed through the skin following direct contact with the substance in an environmental medium. For soil, this process requires adherence of the soil to the skin, desorption of a chemical from the soil, and subsequent absorption through the skin.

Inhalation. Inhalation exposures can occur when a substance is present in an individual's breathing zone. Once inhaled, a substance can be either exhaled or retained in the pulmonary system. Retained substances can diffuse through respiratory-tract surfaces into the blood stream, interact directly with lung cells, or become entrained in airway mucous, translocate up to the pharynx, and be swallowed into the gastrointestinal tract. Inhalation exposures to COPCs can occur by inhaling dust or particulates to which the COPCs are adsorbed, and by inhaling vapors in air.

Inhalation of dust or particulars can occur if soil is disturbed by wind, vehicle traffic, or human activity such as construction/excavation, and releases dust into the breathing zone of the air. Generally, only the particulate fraction in air that is 10 micrometers or smaller, termed the PM10 fraction of particulates, is available for inhalation.

Inhalation exposures to vapors can occur when volatile substances are released from soil to ambient (outdoor) air or when VOCs migrate from soil to air within an occupied building (this pathway is referred to as vapor intrusion). The vapor intrusion pathway is not complete because no occupied buildings will be located at the TSCA Site.

3.2.2.4 *Potentially Complete Exposure Pathways*

That exposure pathways that may be complete at the TSCA Site include:

- Commercial worker and visitor incidental ingestion, dermal contact, and dust and vapor inhalation exposure to unpaved soil.
    - Under current conditions, only small amounts of unpaved soil are present adjacent to Cypher Street and near the South Boston Bypass Haul Road. The Parking Lot Backfill is the soil that is nearest to the ground surface and is therefore representative of the unpaved soil to which receptors would potentially be exposed to under current use conditions.
    - Under future use conditions, the TSCA site will be the same as current conditions (the majority of the area paved, with small isolated unpaved areas); potential exposures to soil by commercial workers and visitors are therefore unlikely. However, potential exposures to surface soil are evaluated for these receptors to help determine if parking lot pavement must remain in-place to mitigate potential exposures. The 0 – 2 ft bgs soil data set is used to evaluate future surface soil exposures to commercial workers and visitors.

- Construction worker incidental ingestion, dermal contact, and dust and vapor inhalation to soil. This assumes that a construction or utility worker engaged in maintenance or improvements at the TSCA Site could contact:
    - soil beneath parking lot; the 0 – 2 ft bgs soil data set is used to represent soil that could potentially be contacted by construction workers during maintenance or repair of the parking

lot

- soil at and beneath and adjacent to Cypher Street; the Cypher Street (0 – 15 ft bgs) data set is used to represent soil that could potentially be contacted by construction workers who maintain or improve Cypher Street.

3.2.2.5 *Incomplete Exposure Pathways*

There are no complete exposure pathways to soil beneath the EM-1 Cap and soil deeper than El. 17 at areas outside of the EM-1 Cap because deed restrictions will require that any soil that is excavated from these locations and depths be managed under a soils management plan and health and safety plan.

3.3 ESTIMATION OF EXPOSURE POINT CONCENTRATIONS

The USEPA defines the EPC as the representative chemical concentration a receptor may contact in an exposure area over the exposure period (USEPA, 1989). Separate EPCs are calculated for each COPC at exposure point.

The typical concept of human exposure within a defined exposure area is that an individual contacts the contaminated medium on a periodic and random basis. Because of the repeated nature of such contact, the human exposure does not really occur at a fixed point but rather at a variety of points with equal likelihood that any given point within the exposure area will be the contact location on any given day. Thus, exposure areas should be identified in consideration of the likelihood of a receptor contacting all areas within the exposure area with equal probability, and the EPCs should be the arithmetic averages of the chemical concentrations within the exposure area. However, to account for uncertainty in estimating the arithmetic mean concentration, the USEPA recommends that an upper confidence limit (UCL) on the mean be used to represent the EPC. In accordance with USEPA guidance (USEPA, 2002a), EPCs for soil are based on the lesser of the 95 percent UCL on the arithmetic mean concentration (95% UCL value) or the arithmetic mean in the data set.

- The 95% UCL values are calculated using the ProUCL software (V. 5.0; USEPA, 2014). The ProUCL software performs a goodness-of-fit test that accounts for data sets without any non-detect observations, as well as data sets with non-detect observations. The software then determines the distribution of the data set for which the EPC is being derived (e.g., normal, lognormal, gamma, or non-discernable), and then calculates a conservative and stable 95 percent UCL value in accordance with the framework described in "Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites" (USEPA, 2002a). The software includes numerous algorithms for calculating 95% UCL values, and provides a recommended UCL value based on the algorithm that is most applicable to the statistical nature of the data set.

- The arithmetic mean concentrations for lead are calculated using the average of all detected values.

Tables D-1 through D-5 present the 95% UCLs and selection of EPCs. UCL calculations are documented in Attachment B. EPCs for PCBs are based on 95% UCL values for total PCBs.

3.4 ESTIMATION OF INTAKES

3.4.1 Exposure Scenarios

Exposure scenarios are used to quantitatively describe the COPC exposures that could theoretically occur for each land use and exposure pathway evaluated. The exposure scenarios are used in conjunction with EPCs to derive quantitative estimates of COPC intake or exposure. The ultimate goal of developing exposure scenarios, as defined in USEPA guidance, is to identify the combination of exposure parameters that results in the most intense level of exposure that may "reasonably" be expected to occur under the current and future site conditions (USEPA, 1989). As such, a single exposure scenario is often selected to provide a conservative evaluation for the range of possible receptors and populations that could be exposed at the TSCA Site under a given land use. For example, when evaluating commercial land use, a commercial worker scenario that is modeled to be protective for the full time workers who are employed at the facility (i.e., people who are there all the time) is protective for all other receptor populations (such as visitors, landscaper workers) and, therefore, it unnecessary to also evaluate those other, less-exposed, receptor populations.

The exposure scenarios that are used to evaluate health risks associated with the potentially complete exposure pathways for possible future land use conditions are described below. EPA has established default exposure assumptions for quantifying theoretical exposure doses of COPCs for the scenarios listed below (EPA, 2002; 2014). Where default exposure parameters were not available, parameters were identified based on professional judgment to reflect site-specific conditions. Exposure parameters are presented in Table D-6. The exposure scenarios evaluated in this risk assessment are:

- Commercial worker: A full-time employee (adult worker) who is assumed to work indoors (e.g., office worker) but be exposed to soil outdoors (e.g., on breaks) 250 days per year over a 25-year period.

- BCEC visitor: Children, adolescents, and adults who are assumed to visit the TSCA Site and be exposed to soil in the landscaped area two days per week during non-winter months over the course of 26 years.

- Future construction worker: An adult worker who is assumed to be involved in earthwork and other activities 5 days per week for 50 weeks over a one-year period. For this scenario, enhanced soil ingestion and dermal contact rates are used to simulate more intensive contact that might be associated with earth work activities.

3.4.2 Intake Equations

Exposures to COPCs are quantified by calculating intakes for representative receptor populations that may use or access the TSCA Site under the various future land use conditions. This section describes the process that is used to quantify PCB exposure.

The process for calculating intakes involves quantifying the amount of COPCs within each exposure point that a receptor population is exposed to, by considering the types of activities that a receptor population would be engaged in (e.g., excavation work vs. working indoors) and the ages of the receptor population (e.g., children vs. adults). From this information, receptor exposure scenarios are developed that relate the activities that could result in exposure to values that can be used to quantify exposure. The quantitative values are called exposure parameters.

Fundamentally, intake is thus a function of EPC and exposure parameters:

Intake = (EPC) x (Exposure Parameters)

For ingestion and dermal exposure routes, the general equation for calculating intake is as follows; specific algorithms and parameter values are provided in Attachment D:

$$Intake = \frac{EPC \times CR \times EF \times ED \times CF}{AT \times BW}$$

Where:

Intake	=	Average daily intake of COC from soil or water at the exposure point during the period of exposure (mg/kg/day)
EPC	=	Exposure Point Concentration (mg/kg)
CR	=	Contact Rate (mg/day) Ingestion: Ingestion rate (mg/day) Dermal absorption: Skin surface area (cm^2/day) x adherence factor (mg/cm^2) (soil) x absorption factor (unitless)
EF	=	Exposure Frequency (days/year)
ED	=	Exposure Duration (years)
CF	=	Conversion Factor
AT	=	Averaging Time (days) (equal to ED for non-cancer evaluation; equal to 70 years for cancer evaluation)
BW	=	Body Weight (kg)

The intake is calculated as an average daily intake or an average daily lifetime intake. The average daily intake represents the total intake that occurs over the period of exposure, divided by duration of exposure. This intake term is used to quantify intakes for evaluating non-carcinogenic effects. The average daily lifetime intake represents the total intake that occurs over the period of exposure, divided by the length of a lifetime (defined by EPA as 70 years). This intake term is used to quantify intakes for evaluating carcinogenic effects.

The methodology for evaluating inhalation exposures differs from that used for other exposure pathways in that the toxicity values used are reference concentrations (RfCs) and unit risks (URs) instead of reference doses (RfDs) and cancer slope factors (CSFs) (USEPA, 2009a). Because concentration and not dose is the basis for these toxicity values, body weight, and respiration rate are not directly used in calculating risk estimates for carcinogenic and non-carcinogenic chemicals. The general equation for calculating chemical exposure via inhalation is as follows:

$$Exposure\ Concentration = \frac{CA \times ET \times EF \times ED}{CF \times AT}$$

Where:

Exposure Concentration = representative concentration of PCBs in the air at the exposure point during the period of exposure (mg/m^3)

CA = concentration of the COC in air (mg/m^3),

EF = exposure frequency (days/year),

ED = exposure duration (years),

ET = exposure time (hours/day)

CF = conversion factor (24 hours/day)

AT = averaging time (for carcinogens, AT = 70 years times 365 days per year; for noncarcinogens, AT = ED times 365 days per year).

The specific equations used to calculate intake and exposure are those presented in EPA guidance (USEPA, 1989; 2004; 2009a), and are provided in Attachment C.

4 TOXICITY ASSESSMENT

The purpose of the toxicity assessment is to weigh available evidence regarding the potential for particular contaminants to cause adverse effects in exposed individuals; and to provide, where possible, an estimate of the relationship between the extent of exposure to a contaminant and the increased likelihood of adverse effects (EPA, 1989). The toxicity assessment is composed of two parts:

- Hazard Identification - Hazard identification is the process of determining whether the exposure to a contaminant can cause an increase in the incidence of a particular adverse health effect. Hazard identification also involves characterizing the nature and strength of the evidence that adverse effects may occur as a result of exposure to an agent; and

- Dose Response Evaluation - Dose response evaluation is the process of quantitatively evaluating the toxicity information and characterizing the relationship between the dose of the contaminant received and the incidence of adverse health effects in the receptors. From this quantitative dose-response relationship, toxicity values can be derived to estimate the potential for adverse effects in receptors that may have been exposed to different concentrations of the specific agent.

In accordance with EPA guidance, hazard identification and dose-response evaluation are performed for non-carcinogenic health effects and carcinogenic health effects. Separate toxicity values are identified for each of these endpoints and risks are characterized separately for each of these endpoints.

Non-cancer Toxicity Values

The noncarcinogenic toxicity values used in the risk calculations for chronic exposure periods (exposures lasting seven years or more) include the chronic reference dose (RfD) for oral and dermal exposures and the chronic reference concentration (RfC) for inhalation exposures. RfD and RfC values represent the dose (RfD) or air concentration (RfC) that is associated with no observable adverse health effects for all populations (including sensitive subpopulations) and are derived from animal studies or human epidemiological studies. Chronic toxicity values were used for the commercial worker and visitor scenarios.

Subchronic exposures are considered to be exposures lasting from several days up to 7 years. Subchronic RfD and RfC values have been developed to evaluate these exposures and are used for the construction worker scenario. Where subchronic toxicity values are not available, the chronic RfD and RfC values for are used as a substitute.

Cancer Toxicity Values

Toxicity values for compounds producing carcinogenic effects are the Cancer Slope Factor (CSF) or the Unit Risk (UR) for oral/dermal and inhalation exposures, respectively. Unlike RfD or RfC values, most CSF and UR values are based on the assumption that there is no threshold dose for carcinogenicity; i.e., there is no dose at which there is no risk of developing cancer. CSF and UR values are derived by EPA using data obtained from animal studies or human epidemiological studies. The CSF is considered to be a measure of the cancer-causing potential of a substance as a result of continuous exposure throughout a lifetime (assumed to be 70 years), and is defined as the 95 percent upper confidence limit of the slope of the dose-response curve extrapolated to low doses.

USEPA has developed new carcinogen risk assessment guidelines (USEPA, 2005a) that revise and replace the previous carcinogen risk assessment guidelines. However, the carcinogen risk assessments for many

of the constituents listed in USEPA's IRIS database still follow the classification system developed in the previous guidance (USEPA, 1999). The classification system in the previous guidance was developed according to the weight of evidence from epidemiologic and animal studies:

Group A - Human Carcinogen (sufficient evidence of carcinogenicity in humans)

Group B - Probable Human Carcinogen (B1 - limited evidence of carcinogenicity in humans; B2 – sufficient evidence of carcinogenicity in animals with inadequate or lack of evidence in humans)

Group C - Possible Human Carcinogen (limited evidence of carcinogenicity in animals and inadequate or lack of human data)

Group D - Not Classifiable as to Human Carcinogenicity (inadequate or no evidence)

Group E - Evidence of Noncarcinogenicity for Humans (no evidence of carcinogenicity in adequate studies)

In the previous guidance, it was assumed that there is some finite level of risk associated with each non-zero dose. The USEPA has developed computerized models that extrapolate dose-response relations observed at the relatively high doses used in animal studies to the low dose levels encountered by humans in environmental situations. The mathematical models developed by USEPA assume no threshold, and use both animal and human data (where available) to develop a potency estimate for a given constituent. The potency estimate for oral and dermal exposure, called a cancer slope factor (CSF) is expressed in units of $(mg/kg\text{-}day)^{-1}$; the higher the CSF, the greater the carcinogenic potential. The potency estimate for inhalation exposures, called a unit risk factor (URF), is expressed in terms of $(ug/m^3)^{-1}$; the higher the URF, the greater the carcinogenic potential.

USEPA (2005a) places greater emphasis on critically evaluating all available data from which a default option may be invoked if needed in the absence of critical information. The guidance also emphasizes the use of mode of action data. Mode of action is defined as a sequence of key events and processes, starting with interaction of an agent with a cell and resulting in cancer formation. Some modes of action are anticipated to be mutagenic and are assessed with a linear approach. Other modes of action may be modeled with either linear or nonlinear approaches after a rigorous analysis of available data under the guidance provided in the framework for mode of action analysis. USEPA (2005a) uses a weight of evidence narrative rather than the classification system that was used in the previous guidance. The following descriptors are recommended along with the weight of evidence narrative:

- Carcinogenic to humans – this descriptor indicates strong evidence of human carcinogenicity.
- Likely to be carcinogenic to humans – this descriptor is appropriate when the weight of evidence is adequate to demonstrate carcinogenic potential to humans.
- Suggestive evidence of carcinogenic potential – this descriptor is appropriate when the weight of evidence is suggestive of carcinogenicity; a concern for potential carcinogenic effects in humans is raised, but the data are judged not sufficient for a stronger conclusion.
- Inadequate information to assess carcinogenic potential – this descriptor is appropriate when available data are judged inadequate for applying one of the other descriptors.
- Not likely to be carcinogenic to humans – this descriptor is appropriate when the available data are considered robust for deciding that there is no basis for human hazard concern.

More than one descriptor can be used when a constituent's effects differ by dose or exposure route. While these represent important advances in carcinogen risk assessment, the approach has not

generally been implemented for constituents with toxicity values on IRIS. Therefore, the alphanumeric system is still presented on IRIS and is included here.

Relative Absorption Factors

Relative absorption factors, which relate the amount of COC absorbed from soil at the TSCA Site to the amount of COC that was absorbed during the toxicological studies that formed the basis of the toxicity values, were established at a value of 1 for ingestion exposures to COPCs, per EPA guidance. Dermal absorption factors were obtained from USEPA guidance (USEPA, 2004b) and are shown in Attachment D.

Sources of Toxicity Values

EPA-approved sources of toxicity values were reviewed to identify current toxicity values for the COPCs, following EPA's guidance regarding the hierarchy of sources of human health dose-response values in risk assessment (USEPA, 2003a), as updated (USEPA, 2013b). The sources used for this HHRA evaluation include:

- *IRIS* (http://www.epa.gov/iris/). (USEPA, 2016b) The main source of dose-response values is Integrated Risk Information System (IRIS), which is a database established by USEPA containing all validated data on many toxic substances found at hazardous waste sites. This database, current as of May 2016, was used to identify the CSFs, URs, RfDs, and RfCs applied in this risk assessment.

- *National Center for Environmental Assessment (NCEA) provisional peer reviewed toxicity values (PPRTVs)* (http://hhpprtv.ornl.gov/). *(USEPA, 2016a)* NCEA's PPRTVs are developed by the Superfund Technical Support Center (STSC) for the USEPA Superfund program. STSC's reassessment of USEPA Health Effects Assessment Summary Tables (HEAST) toxicity values, as well as development of PPRTVs in response to Regional or Headquarters Superfund program requests, are consistent with Agency practices on toxicity value development, use the most recent scientific literature, and are supported by both internal and external peer review, providing a high level of confidence in the use of these values in the Superfund Program. PPRTVs are current as of May 2016.

- *California Environmental Protection Agency (CALEPA)* toxicity values (CALEPA, 2014). CALEP develops toxicity values for both cancer and non-cancer effects. CALEPA toxicity values are obtained on the CALEPA website at http://www.oehha.ca.gov/risk/chemicalDB//index.asp. CALEPA toxicity values are current as of 2011 (cancer toxicity data) and June 2014 (non-cancer toxicity data).

- *Agency for Toxic Substances and Disease Registry (ATSDR's) Minimal Risk Levels (MRLs)* (ATSDR, 2016) address noncancer effects only, and are available on the ATSDR website at http://www.atsdr.cdc.gov/mrls.html. MRL values for intermediate exposure were used as subchronic RfD and RfC values, and MRL values for chronic exposure were used as chronic RfD and RfC values. The MRL values are current as of December 2014.

Per EPA, the recommended values for Tier 3 sources are presented below in order of hierarchy. These values are used as the defaults in the RSL tables.

(1) The ATSDR Minimal Risk Levels (MRLs)
(2) Cal/EPA, Office of Environmental Health Hazard Assessment (OEHHA), toxicity values
(3) PPRTV Appendix "Screening Toxicity Values"
(4) HEAST

Toxicity Values for PCBs

EPA publishes chronic RfD values for Aroclor-1016 and Aroclor-1254 in the IRIS data base, and ATSDR publishes a subchronic MRL for Arolcor-1254; no chronic or subchronic RfD values are published for other Aroclors in the EPA-approved sources listed above. The chronic RfD and subchronic MRL values for Aroclor-1254 are used as RfDs for total PCBs in this HHRA.

Although EPA considers evidence of PCB-induced carcinogenicity in humans to be inadequate, EPA identifies PCBs as a Group B2 probable human carcinogen, based on findings of statistically significant, dose-related increases in liver adenomas and carcinomas in laboratory rats exposed to Aroclor mixtures (EPA, 2015). EPA publishes cancer slope factor and unit risk values for total PCBs. In accordance with guidance provided in the IRIS file for PCBs (EPA, 2015), the upper-bound slope factor and unit risk values for 'high risk and persistence' are used to quantify cancer risks for total PCBs in this HHRA because exposure routes include incidental ingestion of soil and inhalation of dust. Toxicity values for PCBs and other COPCs at the Site are presented in Table D-6.

Evaluation of Lead

EPA does not publish toxicity values for lead, but instead recommends use of biokinetic models to estimate blood lead levels that could result following exposure to lead in environmental media. The Adult Lead Model (ALM) is used with EPCs for lead in soil to estimate blood lead levels in the adult worker populations that are evaluated in this risk assessment. The blood lead levels are then compared to threshold blood lead levels established by EPA, as discussed in Section 5. Potential exposures to child pedestrian visitors are evaluated using the EPA residential soil lead screening level as published in the RSL Table (EPA, 2015a).

5 RISK CHARACTERIZATION

Risk characterization, including uncertainty analysis, is the final step in the risk assessment process. The risk characterization integrates the exposure and toxicity information generated in previous sections to qualitatively or quantitatively evaluate the potential health risks associated with exposure to chemicals at the TSCA Site. Risk estimates are then evaluated through a comparison to risk threshold criteria. Section 5.1 provides the methodology used to calculate risks for each COPC and sum risk estimates among COPCs, exposure pathways, and exposure media to derive cumulative receptor risks. Section 5.2 provides the risk assessment results for each of the land use scenarios evaluated in the HHRA. Section 5.3 provides an assessment of uncertainties in the HHRA.

5.1 RISK CHARACTERIZATION METHODS

Quantitative estimates of both carcinogenic and non-carcinogenic risks are calculated for each exposure scenario selected for evaluation in the exposure assessment, in accordance with USEPA (1989) guidance. Cancer risks associated with exposure to each COPC are calculated by multiplying the exposure route pathway-specific intake (e.g., oral exposure to groundwater) or exposure concentration (e.g., inhalation of dust) by its exposure route-specific CSF (e.g., oral CSF) or UR.

$$\textit{Intake (mg/kg/day or ug/m}^3\textit{) x CSF (mg/kg/day)}^{-1}\textit{ or UR (ug/m}^3\textit{)}^{-1} = \textit{ELCR}$$

The calculated value is an Excess Lifetime Cancer Risk (ELCR) and represents an upper bound of the probability of an individual developing cancer over a lifetime as the result of exposure to a COPC. This process is repeated for all exposure pathways for each receptor at each exposure point.

Non-cancer risks associated with exposure to each COPC are calculated by dividing the exposure route pathway-specific intake (e.g., oral exposure to groundwater) or exposure concentration (e.g., inhalation of dust) by its exposure route-specific RfD or RfC.

$$\textit{Intake (mg/kg/day or ug/m}^3\textit{) / RfD (mg/kg/day) or RfC (ug/m}^3\textit{) = HQ}$$

The calculated value is a hazard quotient (HQ). Chemical-specific HQs are then summed among all exposure pathways for each receptor to produce a hazard index (HI). An HI less than 1 indicates that non-carcinogenic toxic effects are unlikely to occur as a result of COPC exposure. HIs greater than 1 may be indicative of a possible non-carcinogenic toxic effect. As the HI increases, so does the likelihood that adverse effects might be associated with exposure. The text discussions in the Risk Characterization identify HI values based on the child receptor for pedestrian visitor scenario because the HI values for the child receptor are higher than HI values for the adolescent and adult receptors.

5.2 RISK CHARACTERIZATION RESULTS

The relative significance of the calculated risks is evaluated in terms of a comparison with acceptable risk levels established in the USEPA National Contingency Plan (NCP, 1990). In accordance with the NCP, cancer risk estimates for a site are compared to an ELCR range of 10^{-6} (one in a million) to 10^{-4} (one in ten-thousand). Risks at or below 10^{-6} do not warrant a response action, risks greater than 10^{-4} generally warrant a response action, and the decision to require a response action for risks that are between 10^{-6} and 10^{-4} is a risk management decision that is made by USEPA. Non-cancer risks are compared to a HI

value of 1, which corresponds to levels of exposure that people (including sensitive individuals such as children) could experience without expected adverse effects.

The HI that is calculated by summing the HQs for all COPCs generally provides an overestimation of potential non-cancer risk. This is because the HI for each COPC represents the ratio of the estimated COPC intake to the threshold dose for a *specific* adverse health effect, where the adverse health effect is determined by the basis of the RfD and RfC. Summing HQs that are based on risks for different adverse health effects does not provide an estimate of total risk for a specific adverse health effect. Therefore, according to USEPA guidance (USEPA, 1989), a total HI that is above one and is based on exposures to multiple COPCs does not necessarily indicate that the potential for adverse health effects is unacceptable if the risks for the COPCs are not additive. Consequently, in the HHRA, separate HI values for specific target organ effects may be calculated by summing the HQ values for COPCs that affect the same target organ(s). This approach is generally only used when there are no COPCs with HQs greater than one, but the sum of HQs results in an HI greater than one.

Table D-8 provides cumulative receptor risks for each of the exposure scenarios evaluated in this risk assessment.

- Parking Area Backfill: Parking Area Backfill was used to represent potential exposures to unpaved soil under current use conditions. HI values for potential exposures to this soil range from 0.1 (commercial worker) to 0.3 (visitor) and ELCR values range from 9E-06 (visitor) to 1E-05 (commercial worker).

- Surface Soil 0 – 2 ft: Surface soil was used to evaluate whether parking lot pavement will be required to mitigate exposures and potential risks under future use conditions, under the assumption that if the parking lot was to not be paved, commercial workers and visitors could be exposed to surface soil 0 – 2 ft bgs. HI values for potential exposures to this soil range from 0.5 (commercial worker) to 1 (visitor) and ELCR values range from 1E-05 (visitor) to 2E-05 (commercial worker).

  Construction workers were also evaluated for potential exposures to surface soil (0 – 2 ft) under the assumption that pathways could be complete during parking lot maintenance or improvement activities. The HI for the construction worker is 0.9 and the ELCR is 2E-06.

- Cypher Street Area: Soil 0 – 15 ft bgs beneath and adjacent to Cypher Street was evaluated for potential exposures by construction workers under the assumption that Cypher Street may be improved in the future. The HI is 0.8 and the ELCR is 1E-06.

These results indicate that cumulative risks for PCBs and other COPCs are within the NCP cancer risk range of 10^{-6} to 10^{-4} and do not exceed a hazard index of 1.

EPCs for lead in Parking Lot Backfill (137 mg/kg) and Soil 0 – 2 ft (208 mg/kg) are well below the EPA lead screening value for residential soil of 400 mg/kg (USEPA, 2016a). This indicates that lead concentrations in those exposure points do not pose risks of concern to commercial workers, visitors, or construction workers.

For Cypher Street soil (0 – 15 ft bgs), the lead EPC (1048 mg/kg) is greater than the RSL for industrial soil of 800 mg/kg (USEPA, 2016a), indicating that further evaluation is required. As described in Section 4,

risks associated with potential exposures to lead in soil are characterized using the ALM. To evaluate the significance of the estimated blood lead concentrations, the blood lead concentrations are compared to a threshold blood lead level of 10 micrograms per deciliter (µg/dL). This threshold blood lead level is a multi-agency goal that has been designated by the U.S. Centers for Disease Control (CDC) and the ATSDR as a level of concern to protect sensitive populations, including neonates, infants, and children. The protection of sensitive populations is assumed to also provide protection for adults. USEPA indicates that 95% of the exposed population should have a geometric mean blood lead level that does not exceed 10 µg/dL.

The results of this analysis indicate that the estimated blood lead level for a worker (2.8 ug/dl) and a fetus carried by a worker (6.7 ug/dl) are below 10 ug/dl, indicating that lead does not pose a risk of concern in that area.

Based on the HHRA results, the PCB remediation planned for the TSCA Site will result in post-remediation conditions associated with health risks that do not exceed EPA risk management criteria; excess lifetime cancer risks will be within the NCP cancer risk range and Hazard Index values will not exceed 1. Furthermore, the HHRA results indicate that maintenance of pavement at the parking lot is not required to maintain acceptable health risks.

5.3 UNCERTAINTY ANALYSIS

5.3.1 Inherent Sources of Uncertainty

Since the assumptions and other aspects of risk assessments are intended to be conservative, some degree of uncertainty is inherent to the process. Inherent sources of uncertainty typically relate to four areas:

1.) the site characterization process;
2.) the exposure assessment;
3.) the toxicity assessment; and
4.) the risk characterization.

Inherent sources of uncertainty relating to the site characterization process include:

- Field Sampling location bias (sample locations were biased toward areas of highest contamination);
- Lack of consideration of source depletion, natural degradation or attenuation of COPCs over time; and
- Limitations on the determination of background conditions.

Inherent sources of uncertainty relating to the exposure assessment include:

- Assumption that exposure scenarios and contact with affected media will occur;
- Selection of the 95% UCL of the mean, or the maximum concentration, for the exposure point concentration;
- Assumption of frequent, or routine exposure over prolonged durations;
- Use of default exposure values for physiological parameters such as skin surface area and soil ingestion rates; and
- Assumption that some pathways are negligible in comparison to others.

Inherent sources of uncertainty relating to the toxicity analysis include:

- Use of published RfDs and SFs derived by standard EPA methods;
- Assumption of bioavailability of COPCs from soil.
- Use of toxicity data based on Aroclor mixtures.

Inherent sources of uncertainty relating to the risk characterization include:

- Assumption of additivity of toxicological effects; and
- Risk characterization does not consider antagonistic or synergistic effects. Little information is available to determine the potential for antagonism or synergism for the COPCs.

5.3.2 Site Specific Sources of Uncertainty

In addition to the uncertainties inherent in the risk assessment process, there are typically uncertainties associated with site-specific information, contaminants or conditions. The following TSCA Site-specific sources of uncertainty apply to this study area:

- The soil analysis used the Aroclor method instead of the congener specific method. Given that the toxicity information is based on Aroclor mixtures, this uncertainty should be mitigated to some degree.

- The future commercial worker scenarios assume exposure to soils every work-day for a 25-year period. Similarly, the BCEC visitor scenario assumes the people from birth to age 26 access soils at the Site 3 days per week spring, summer, and fall. In reality, the site will remain paved and the potential for exposure to soil will be almost non-existent. Therefore, these exposure evaluations overestimate the potential future human health risk.

6 SUMMARY AND CONCLUSIONS

The risk assessment evaluated potential exposures and health risks associated with PCBs and other chemicals of potential concern under conditions which assume a specific remedial plan which will include:

- Remediation of soil containing total PCBs greater than 500 mg/kg
- Remediation of discrete areas of soil containing non-PCB constituents (e.g., lead) at concentrations greater than MCP Upper Concentration Limits.

Based on this remedial plan, the results of the risk assessment indicate that none of the potentially complete exposure pathways that could exist after TSCA Site remediation would be associated with cancer and non-cancer risks that exceed EPA risk management thresholds. Specifically, the conclusions of the risk assessment are as follows:

- For a commercial worker and visitor, the only exposure pathways that may realistically be complete at the TSCA Site are those associated with surface soil (Parking Area Backfill) at small unpaved areas, which do not pose risks in excess of EPA risk management thresholds. In addition, the HHRA demonstrates that surface soil (0 – 2 ft) at the Site could remain unpaved in the future and would not pose risks in excess of EPA risk management thresholds if exposure were to hypothetically occur.

- For a construction worker, the TSCA Site does not pose risks in excess of EPA risk management thresholds for:
  - soil beneath and adjacent to Cypher Street;
  - surface soil (0 – 2 ft) at the TSCA Site

- Potential exposures to subsurface soil at the Site, both beneath and outside of the EM-1 Cap, will not occur because deed restrictions will require soil management and health and safety plans that will mitigate any potential exposures.

These results are summarized in Table D-8.

ABBREVIATIONS:
- COPC = compound of potential concern
- EPC = exposure point concentration
- mg/kg = milligram per kilogram
- UCL = upper confidence limit

NOTES:
- Only compounds detected above laboratory detection limits at least once are listed.
- Compounds were excluded as COC if the maximum detected levels in site-wide data did not exceed November 2015 Industrial Soil RSL (HI=0.1).
- Average levels are calculated as the arithmetic mean and use values of 1/2 the reporting limit for constituents that were not detected.
- Soil EPC is the lesser of the maximum detected level or the calculated 95% UCL of the COC.
- 95% UCL values calculated using ProUCL v. 5.0.00.

The average for Total PCBs uses 1/2 the detection limit for those samples for which no aroclors were detected.

ABBREVIATIONS:
- COPC = compound of potential concern
- EPC = exposure point concentration
- mg/kg = milligram per kilogram
- UCL = upper confidence limit

NOTES:
- Only compounds detected above laboratory detection limits at least once are listed.
- Compounds were excluded as COC if the maximum detected levels in site-wide data did not exceed November 2015 Industrial Soil RSL (HI=0.1).
- Average levels are calculated as the arithmetic mean and use values of 1/2 the reporting limit for constituents that were not detected.
- Soil EPC is the lesser of the maximum detected level or the calculated 95% UCL of the COC.
- 95% UCL values calculated using ProUCL v. 5.0.00.

The average for Total PCBs uses 1/2 the detection limit for those samples for which no aroclors were detected.

ABBREVIATIONS:
- EPC = exposure point concentration
- mg/kg = milligram per kilogram

NOTES:
- Only compounds detected above laboratory detection limits at least once are listed.
- Compounds were excluded as COC if the maximum detected levels in site-wide data did not exceed November 2015 Industrial Soil RSL (HI=0.1).
- Average levels are calculated as the arithmetic mean and use values of 1/2 the reporting limit for constituents that were not detected.
- Soil EPC is the average detected level of the COC.

The average for Total PCBs uses 1/2 the detection limit for those samples for which no aroclors were detected.

Age-Adjusted Dermal Contact Factor	DFSadj	mg-yr/kg-day	NA		NA		NA		360		130		13	
Particulate Inhalation														
Exposure Time	ET_{Part}	hours/day	2	Site-specific [2]	2	Site-specific [2]	2	Site-specific [2]	2	Site-specific [2]	8	EPA, 2014	8	EPA, 2002
Vapor Inhalation														
Exposure Time	ET_{Vap}	hours/day	2	Site-specific [2]	2	Site-specific [2]	2	Site-specific [2]	2	Site-specific [2]	8	EPA, 2014	8	EPA, 2002
Exposure Interval	s	seconds							8.2E+08	Equal to scenario ED	7.9E+08	Equal to scenario ED	3.2E+07	Equal to scenario ED

NOTES:
EPA, 2011 - Exposure Factors Handbook. EPA/600/R-10/030. October, 2011.
EPA, 2014 - Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. OSWER 9200.1-120. February 6, 2014
[1] - Table 8-1 of EPA (2011), Recommended Values for children ages 6 - <11 and 11 - <16;
[2] - Use as a parking lot. Assumes 2 visits per week, spring, summer, and fa
[3] - These populations are based on their age range (10 years for 6 - 16) and the balance of years that constitute a default 26-year residential exposure duratio
[4] - Based on surface area of face, hands, forearms, lower legs for children ages 6 - <11 and 11 - <16 and adherence factor for 'activities with soi
[5] - Cypher Street area is a small strip of land; utility and roadwork at street would realistically not require more than two months of construction work. The EF for that area is therefore 40 day
Values are based on time-weighted average of child, adolescent, and adult exposure values, calculated as follow
EF = (child EF x child ED) + (adolescent EF x adolescent ED) + (adult EF x adult ED) / total scenario E
IFSadj = (child ED x child IR / child BW) + (adolescent ED x adolescent IR / adolescent BW) + (adult ED x adult IR / adult BV
DFSadj = (child ED x child SA x child AF / child BW) + (adolescent ED x adolescent SA x adolescent AF / adolescent BW) + (adult ED x adult SA x adult AF / adult B
ET = (child ET x child ED) + (adolescent ET x adolescent ED) + (adult ET x adult ED) / total scenario E

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.

ABBREVIATIONS:
-: Not Analyzed
mg/kg: milligram per kilogram
mg/L: milligram per liter
mV: millivolts
ND (2.5): Not detected, number in parentheses is the laboratory reporting limit
NI: Not Ignitable

NOTES:
1. Volatile and Semi-Volatile Compounds detected in at least one sample shown above. For a complete list see the laboratory data sheets.
