SEDIMENT TOXICITY TESTING

INTRODUCTION

During the month of October, 2006 samples were collected from the LCP Chemicals, Inc. Superfund site in Linden, New Jersey as described in the *Brown and Caldwell Supplemental Work Plan: Sediment Toxicity Testing (South Branch Creek) Phase II Remedial Investigation LCP Chemicals, Inc. Superfund Site,* dated September 2006. These sediment samples were used to perform acute toxicity tests to determine if the tested matrices represent a significant threat to potential receptor organisms.

The sediment samples from the site were evaluated for toxicity using a 10-day solid phase exposure using the saltwater amphipod *Leptocheirus plumulosus*[1]. Following the exposure period, surviving test organisms from the sediment samples collected at the site were compared to control and reference sediments tested under similar conditions using a water of known environmental quality, laboratory prepared artificial salt water (ASW). The endpoints used for determination of an impact were mortality, measured as mean survival and growth, measured as mean dry weight.

MATERIALS AND METHODS

Sediment samples were collected from the LCP Chemicals, Inc. Superfund site in Linden, New Jersey, as described above. These sites were selected to represent an area that has been impacted by the facility's operations (South Branch Creek) and an off-site Reference Area, which would likely not have been affected. The Reference Area was Old Place Creek, an Arthur Kill tidal inlet in Staten Island, New York. Three samples were collected from South Branch Creek. Two of these were found to emit mercury vapors upon agitation and therefore could not be tested safely. After discussion with and approval by EPA, these samples were properly disposed along with other investigation-derived waste. The sediment toxicity program proceeded with one sample from South Branch Creek and one from the Old Place Creek (the reference sediment).

Preparation of sediment samples for testing

The sediment samples collected were transported to the laboratory in two-gallon HDPE containers on ice. Prior to sieving, each sample was monitored for mercury vapor using a Jerome 4100 mercury analyzer. Of the four samples collected, two were found to be producing mercury vapors at levels that precluded their use in the sediment toxicity analysis. These samples were returned to the site unused. The remaining two samples sieved using a #18 mesh sieve (1000 μm) to remove large debris and indigenous species

that may have either competed with or potentially preyed upon the test organisms. The sieved portion of the sediment was then transferred to new, clean 1-gallon HDPE containers, sealed and stored at 0-4 °C until used for testing on November 3, 2006.

Control sediment used for the test was provided by the culture facility that provided the test organisms. It was collected from Olds House Creek, a tributary to the Chesapeake Bay near Selden, Virginia in October 2006. The control sediment was sieved and all material between 500 and 335 µm used for culture and testing. Prior to testing it was stored in the same manner as the sediment samples from the LCP site.

Test organisms

Study amphipods (*Leptocheirus plumulosus*) were obtained from stock cultures maintained by ABS, Inc. of Fort Collins, CO. During the short holding period prior to test initiation, the organisms were held under conditions similar to those that they would encounter during the test (see Table I). Amphipods were fed once daily prior to testing using crushed flake fish food.[1]. Test organisms chosen for testing were 2 to 4 mm in length, collected on 500 µm sieve after passing through a 710 µm sieve.

Experimental procedures

The entire sediment exposure series for this project consisted of one sediment samples from the LCP Chemicals, Inc., Superfund site, one regional reference sample, and control sediment. Test chambers (1000 mL tall form borosilicate glass beakers) were filled with 200 mL of sediment. Each then had the sediment layer covered with 800 mL of ASW. Each treatment had four replicate chambers. All of the test chambers were allowed to settle for 24 hours prior to test initiation.

After the settling period, porewater was analyzed for ammonia to ensure levels were low enough to introduce test organisms. Overlying water was then siphoned off and fresh laboratory water was introduced, using a round HDPE disk suspended over the sediment to deflect the water flow and minimize disturbance to the sediment. At this time alkalinity, conductivity, dissolved oxygen, pH, salinity and temperature were measured for the overlying water for each test sample and the control.

The exposure period began by placing 20 randomly selected test organisms into intermediate containers prior to introduction into each test chamber, to insure the correct number was added to each chamber. Care was taken to ensure that the organisms were released beneath the surface of the overlying water to keep air bubbles from forcing the organisms to the surface. Test conditions are summarized in Table I.

Each day during the exposure period observations were carried out in each chamber to determine the number of organisms dead, swimming, on the surface of the sediment or on the surface of the water. Dissolved oxygen, pH, salinity and temperature were also

measured. The overlying water was aerated during the entire 10-day exposure with an oil free air source to maintain acceptable dissolved oxygen levels. The aeration was introduced to each chamber via a Pasteur pipette attached to the inside of the test chamber approximately one inch beneath the water surface, to minimize sediment disturbance. The overlying water was not changed during the 10-day exposure, and the test organisms were not fed.

At the end of the 10-day exposure the final alkalinity, ammonia, conductivity, dissolved oxygen, pH, salinity and temperature were measured, and the test chambers were prepared for the removal of test organisms. Each chamber was gently stirred using a pipette to suspend the sediment in the overlying water. This slurry was then poured into a #60 mesh sieve (250 µm) and rinsed in a shallow pan of ASW to remove the finer grains of the sediment. The remaining contents of the sieve were placed into a second shallow pan of ASW, placed over a light table, and carefully sorted to find the surviving test organisms in each of the four replicates for each site. All surviving amphipods for each chamber were transferred to a 30 mL soufflé cup for live count verification and preparation for weight analysis.

When all test chambers had been sorted and the number of survivors verified, 0.5 mL of ethanol was added to each soufflé cup to dispatch the organisms. They were then transferred to a previously dried and tared aluminum pan and placed into an oven to dry at 105° C for a minimum of six hours. Upon removal from the oven, the pans were placed into a desiccator to cool and then were measured to the nearest 0.01 mg.

Data analysis

Data analysis was performed following procedures published by the USEPA[1] using the ToxCalc™ v5.0.23F data analysis software. Survival data were arcsine squareroot transformed, tested for normality and then tested for homogeneity of variances. Due to the small sample size, a two-sample test was used to determine significance. Growth data was not transformed as the data set was found to be normally distributed and had homogeneous variance. A two-sample test was also used to analyze growth due to the small sample size.

All raw data sheets are located in Appendix A.

TABLE I: Summary of Conditions for *Leptocheirus plumulosus* Toxicity Test

1.	Test type:	Whole sediment, static non-renewal
2.	Temperature:	25.0 +/- 1.0° C
3.	Light quality;	Wide-spectrum fluorescent illumination
4.	Light intensity:	50 - 100 foot-candles
5.	Photoperiod:	16 hours light, 08 hours dark
6.	Test chamber size:	1000 mL high form borosilicate glass beakers
7.	Sediment volume:	200 mL / replicate
8.	Overlying water volume:	800 mL / replicate
9.	Renewal:	None
10.	Size of test organisms:	2 to 4 mm in length, retained on a 500 µm sieve
11.	Number organisms / container:	20
12.	Replicates:	4
13.	Feeding:	None
14.	Aeration:	Continuous @ ~ 100 bubbles / min.
15.	Overlying water:	Artificial Salt Water
16.	Test chamber cleaning:	None
17.	Overlying water quality:	Dissolved oxygen, pH, salinity and temperature daily; alkalinity, ammonia, conductivity and hardness at beginning and end of test
18.	Test duration:	10 days
19.	Endpoints:	Survival and growth (mean dry weight)
20.	Test acceptability:	Minimum control survival 90 %

RESULTS

Effects on Survival

For the first of the two endpoints used, survival, the data from the test location was compared to the reference site. The control exposure conducted concurrently was used to establish satisfactory survival for the test organisms and were not used for sample analysis.

Arcsine squareroot transformed data were first analyzed for normality using the Shapiro-Wilk's Test. The data were found to be normal in distribution. Homogeneity of the variances were then tested using an F-Test and variances were found to be homogeneous. The Wilcoxon Two-Sample Test was performed to determine if the test sample was found to be impacted relative to the reference location.

The survival of the control exposures was 95%, which exceeded the minimum requirement of 90% for the method. The survival of the Reference Creek sample met the required 90% survival. Locations A-3 from the LCP site had survival of 56.3%, which was determined to be statistically different from the Reference Creek value. The survival of the test organisms is summarized in Table II by location and replicate.

Effects on Growth

For the second of the two endpoints used. growth, measured as mean dry weight, the data from the test location was compared to the reference site. The control exposure conducted concurrently was used to establish satisfactory growth for the test organisms and was not used for sample analysis.

Data were first analyzed for normality using the Shapiro-Wilk's Test. The data were found to be normal in distribution. Homogeneity of the variances was then tested using an F-Test and variances were found to be homogeneous. The Wilcoxon Two-Sample Test was performed to determine if the test sample was found to be impacted relative to the reference location.

Mean dry weight analysis of test organisms at the end of the 10-day exposure found that the Reference Creek sample and the A-3 sample both exhibited larger mean dry weights than did the control exposure. Further statistical analysis was not necessary. The mean dry weight data should be viewed with caution as the survival endpoint indicates a significant difference between the reference site and the sample collected at the LCP site. It should be noted that both the reference and test samples contained significantly higher amounts of organic matter, which likely contributed to the larger average size. Also, in the test sample there fewer individuals surviving, which may have led to less competition among survivors for food, and/or a reduction is stress relative to the loading of test organisms. The mean dry weights of the test organisms are summarized in Table III by location and replicate.

All statistical analysis is located in Appendix B.

Table II: Percent survival of *L. plumulosus* by replicate chamber and location

	SAMPLE LOCATION		
Rep	Control	Reference Creek	A-3
A	95	95	55
B	95	90	35
C	90	90	65

1. INTRODUCTION

Regional background conditions were investigated as part of the Phase II Remedial Investigation (RI) performed at the LCP Chemicals Inc., Superfund Site in Linden, New Jersey,. Impacts to site sediment, surface water, and biota were investigated. These background conditions include historic regional land use and the ubiquitous presence of certain chemical constituents. Historic land impacts include the filling of former tidal wetlands with anthropogenic fill of industrial origin, which is characteristic of old industrial properties within the New York Harbor area, and which has resulted in a loss and/or substantial degradation of ecological habitats. Furthermore, anthropogenic fill of industrial origin frequently contains elevated levels of PAHs and certain metals that are associated with industrial combustion products often contained within the fill (e.g., bottom ash). The presence of other chemical constituents is also not uncommon in old industrial fill, including trace levels of PCDDs/PCDFs as a result of industrial and transportation-related air deposition. An investigation of regional conditions was conducted in order to further understand which contamination at the LCP Site results from site related activities as opposed to contamination which is the result of regional industrialization.

Investigation of regional conditions included literature searches, review of publicly available analytical databases (as presented in RI Report Section 2.10), and selection and investigation of a tidal channel close to but not under the influence of the site. This field investigation was performed in a tributary to Old Place Creek. A description and results of this program are presented below.

1.1 Site Description

Old Place Creek is a small estuarine tidal creek that consists of salt marshes and an adjacent successional southern hardwood forest. Located in the Gulfport section of Staten Island, New York, the area is surrounded by heavy industrial development,. It connects directly to the Arthur Kill approximately $^{1}/_{10}$ mile northeast of the Goethals Bridge (Interstate 278). Old Place Creek originates as two separate streams. One originates between South Avenue and Goethals Road North, and flows for ½ mile in the westerly direction. The other, which originates between South Avenue and Glenn Street, flows in a northwesterly direction for ½ mile. They connect where Interstate 278 and NYS Route 440 intersect. The creek then flows adjacent to Interstate 278 for about 1¼ miles in a natural flow path, until it flows under the Interstate and follows its path for the last ¼ mile where it enters the tidal marsh at the Gulfport Reach of the Arthur Kill, 1.8 miles north by northeast of the LCP site. The tributary that was investigated drains into Old Place Creek from the north, approximately 0.15 miles east from the discharge of Old Place Creek into the Arthur Kill.

1.2 Site Investigation

The investigations performed in the tributary to Old Place Creek were comparable to those completed in South Branch Creek as part of the Phase II RI at the Site, utilizing the same sample collection techniques and laboratory analyses. Analytical data were collected for surface water, sediment, fiddler crab tissue, and fish tissue. Field oversight was not provided by USEPA.

2. FIELD INVESTIGATION PROGRAM

2.1 Surface Water Samples

Four (4) surface water samples were collected for laboratory analysis from the tributary to Old Place Creek. The surface water samples were collected along transects evenly spaced along the length of the tributary to Old Place Creek, at the locations shown on Figure N-1. The surface water IDs, along with the specific analytical methods employed, are listed on Table N-1a. Descriptions of the surface water sample collection methods are presented in Appendix B (Field Operations Plan, Field Methods).

2.2 Sediment Samples

Twenty (20) sediment samples were collected throughout the tributary to Old Place Creek. The sediment samples were collected along the same transects as the surface water samples, evenly spaced along the length of the tributary to Old Place Creek at the locations shown on Figure N-1. The sediment samples and the specific analytical methods employed are listed in Table N-1b.

Samples were collected at a depth interval of 0 to 0.5 feet at each location. Additional deeper sediment samples were collected at selected locations at 0.5-foot intervals to a maximum depth of 2.5 feet, as listed in Table N-1b.

The sediment samples were collected by two primary methods. Many of the surficial sediment samples were collected as a grab sample with the use of "Petite Ponar" dredge. Sediment samples collected from locations where depths greater than 0.5 feet were collected using a sediment coring device with polycarbonate tubing. Sediment samples targeted for AVS/SEM analysis were collected with minimum disturbance and exposure to air. Descriptions of the sediment sample collection methods are presented in Appendix B (Field Operations Plan, Field Methods).

2.3 Biota Samples

Biota samples were collected from twelve (12) stations in the tributary to Old Place Creek. The biota samples consisted of four Mummichog (*Fundulus heteroclitus*) tissue samples and eight Fiddler Crab (*Uca spp*) tissue samples. The biota samples and analytical methods are listed in Table N-1c.

Biota samples were collected along transects evenly spaced along the length of the tributary to Old Place Creek as shown on Figure N-1, Mummichog samples were collected at the midpoint of the channel, while Fiddler Crab samples were collected along the near shoreline on both sides of the channel.

Mummichog samples were collected using minnow traps. Fish samples were rinsed, weighed, and measured prior to being shipped to the laboratory. Fiddler crab samples were collected by hand capture and similarly rinsed, weighed, and measured before being sent to the laboratory. Descriptions of the biota sample collection methods are presented in Appendix B (Field Operations Plan, Field Methods).

3. PHYSICAL CHARACTERISTICS INVESTIGATION RESULTS

3.1 Wetlands and Ecology

A Habitat Assessments for the tributary to Old Place Creek was completed by The Chazen Companies (TCC) in 2006. The tributary to Old Place Creek was identified as a tidal inlet and is abutted by southern successional hardwood forest (upland to the north) and Estuarine Dredge Spoils/High Salt Marsh (banks). During the field portion of the Habitat Assessment (performed in September 2006), 17 species of plants, 29 species of wildlife, and three ecological communities were identified within the tributary to Old Place Creek. A more detailed description of this Habitat Assessment can be found in the document entitled "Ecological Assessment Report, LCP Chemicals Reference Channel, Staten Island, Richmond County, New York" (August 2007) (Attachment 1).

3.2 Sediment

The sediment bed in the tributary to Old Place Creek is composed of a wide variation of sediment types, ranging from organic to clay and silt to gravelly sediment. The banks of the Creek are native soil.

3.3 Surface Water

The tributary investigated originates in the north and flows south over 250 feet before discharging into Old Place Creek, approximately 800 feet east from where Old Place Creek drains into the Arthur Kill. The watercourse is a little over 50 feet wide and has a large tidal change from low to high tide (i.e., 4-5 feet), resulting in an almost total drainage of the channel during low tide.

4. NATURE AND EXTENT OF CONTAMINATION

The data of the field investigation performed in August and September 2006 were reported in the document entitled "Phase II Site Characterization Summary Report, LCP Chemicals Superfund Site, Linden, New Jersey" (Brown and Caldwell, September 2007), along with the data from the Phase II RI field investigation for the Site. A complete tabular summary of analytical results is presented in Attachment 2.

4.1 Surface Water

Table N-2 presents a summary of descriptive statistics for contaminants detected in surface water samples collected in Old Place Creek. Both chronic and acute toxicity criteria are available for comparison for surface water for various creek constituents including mercury. The chronic value is referred to as Criteria Continuous Concentration (CCC), which is an estimate of the highest contaminant concentration to which an aquatic community can be exposed indefinitely without an unacceptable effect. The acute value, Criterion Maximum Concentration (CMC), is an estimate of the highest contaminant concentration to which an aquatic community can be exposed briefly without an unacceptable effect. Applicable water quality criteria have not been developed for any of the detected chemicals on an unfiltered basis. USEPA National Recommended Water Quality Criteria (NRWQC) for saltwater exist for dissolved arsenic, cadmium, copper, lead, mercury, selenium and zinc; however, filtered inorganics were not analyzed. In addition, due to the tidal influences and the inherently mobile nature of surface water, the surface water data provide limited information on nature and extent of contamination in the water bodies compared with sediment.

There were no detections of chemical constituents at levels above the saltwater Criteria Continuous Concentration (CCC) or Criteria Maximum Concentration (CMC). Mercury was not detected in surface water by standard method (SW7470A); however low levels of mercury were detected during methyl mercury analysis. Methyl mercury was detected at concentrations of 0.5% of the total mercury concentration or less as presented in Table N-3. There were no detections of organic constituents in surface water in Old Place Creek.

4.2 Sediment

Table N-4 presents a summary of descriptive statistics for the sediment samples for Old Place Creek. Figures N-2a through N-4d show the spatial distribution of mercury, arsenic, and the PCBs Aroclor 1248, Aroclor 1254 and Aroclor 1260 in the sediments from Old Place Creek. A summary of selected metals and PCB results are presented in Table N-5.

There are no promulgated regulatory standards for sediment quality. However, the ER-L and ER-M screening values (Long, *et al.*, 1995) were used to provide a context for assessing the sediment data. These screening levels were selected from among several sets of frequently cited benchmarks because they are preferred by the NJDEP (NJDEP, 1998). The ER-Ls and ER-Ms represent the 10th and 50th percentile concentrations, respectively, associated with observed biological effects from systems with multiple contaminants. Correlation between effects and concentrations for many constituents, including mercury, was described by the Long, *et al.* (1995) as "weak." The ER-Ls are used as a threshold below which biological effects are not expected. The ER-Ms are indicators of when effects might be expected. The ER-Ms do not indicate biological hazard, only that additional risk evaluation may be warranted. Tables N-6a and N-6b list

the ER-L and ER-M values for various constituents, along with exceedances of these screening values for Old Place Creek. The ER-L value was exceeded for 23 constituents in at least one sample from Old Place Creek. Eleven chemicals exceeded respective ER-Ms in Old Place Creek.

Mercury was detected and exceeded the ER-L in all 20 sediment samples as presented in Figures N-2a through N-2d. The ER-M was exceeded in 17 of 20 samples. Methyl mercury was detected in 10 of 21 samples. The percentage of methyl mercury in sediment compared to total mercury ranged from 0.01% to 0.39% in samples where it was detected as shown in Table N-7.

AVS/SEM measurements are used as a general indicator of bioavailability of divalent metals (cadmium, copper, nickel, lead, mercury and zinc) in sediment. The major component of AVS; iron sulfide (FeS), reacts with those metals to form metal sulfides. The solubility of these metal sulfides is very low, and they are therefore not considered bioavailable. In sediments that contained a high level of reactive sulfide, the partitioning of divalent metals (Cd, Cu, Ni, Pb, Hg, and Zn) into the aqueous fraction (pore water), which represents the contact medium for aquatic life, will be minimized. Conversely, sediments with SEM greater than AVS are of potential concern with regard to bioavailability from sediment. Specifically, where the AVS/SEM ratio is less than one, there is a potential for the presence of soluble (bioavailable) metals. Table N-8 presents the AVS/SEM results from sediments in Old Place Creek, which ranged from 0.062 in sample SED-W-2 to 27 in sample SED-Z-2 and SED-Z-3.

Sediments collected from Old Place Creek had PCBs detected in 6 samples. Those PCBs were identified as Aroclor 1248 and Aroclor 1260 (Table N-9, Figure N-4a through N-4d) which are the same as those observed in the on-site soils. The ER-L and ER-M concentrations for Aroclor 1254 are .023 mg/kg and 0.18 mg/kg, respectively. Of the samples with detectable PCBs, 30 percent exceeded the ER-L and ER-M thresholds.

Seventeen (17) of the 18 analyzed SVOCs that are classified as polycyclic aromatic hydrocarbons (PAHs) were detected in sediment samples collected from Old Place Creek. The frequency of detection for these 17 chemicals in Old Place Creek samples ranged from 15 to 100 percent. ER-L/ER-M values have been established for 13 of these PAHs. The frequency of ER-L exceedances ranged from 15 to 65 percent. The ER-Ms were exceeded for two of these constituents, in 5 to 15 percent of the samples. The average total PAH concentration in Old Place Creek sediments was 5.41 mg/kg (Table N-10 and Figures N-5a through N-5d). Total carcinogenic PAHs (cPAHs) in sediments and cPAHs normalized to B(a)P are shown on Figures N-6a through N-7d.

In addition to the PCBs and PAHs discussed above, sediment samples were analyzed for 17 polychlorinated dibenzo-p-dioxins and -furans (PCDDs/PCDFs), 21 pesticides and herbicides, 51 non-PAH SVOCs and 46 volatile organic compounds (VOCs). The full suite of analyzed PCDD (dioxin) and PCDF (furan) congeners was detected in almost every sediment sample collected from Old Place Creek (Table N-4).

Another way of looking at these compounds is by normalizing to the most toxic isomer, 2,3,7,8-TCDD. Each of the 17 PCDDs/PCDFs have been assigned a Toxic Equivalency Factor (TEF) by the World Health Organization (WHO, 2005), which is based on the chemical's toxicity relative to TCDD (which has a TEF of 1). Table N-11 also lists the Toxicity Equivalence Quotient (TEQ) for PCDDs/PCDFs. The TEQ is defined as "the sum of the quantity of individual PCDD/PCDF congeners multiplied by the respective TEF." TEQs standardize the toxicity of dioxin compounds to allow comparison of the relative risk in areas of contamination that vary widely in the composition and level of individual PCDD/PCDF compounds. The spatial distribution of TEQ values is presented in Figure N-8.

4.3 Biota

Tables N-12a and b present a summary of descriptive statistics for the fish and crab tissue samples, respectively; Figures N -9a through N-10b show the spatial distribution of mercury and arsenic in these samples. The percentage of methyl mercury in fish and crab tissue is presented in Tables N-13a and b.

Tissue accumulation is not typically a concern for metals. However, the USEPA previously expressed concern about the potential for tissue accumulation and specifically requested tissue analyses for 10 metals. To address the resulting data, Biota-Sediment Accumulation Factors (BSAFs) were calculated for these metals and for total PCB Congeners. The BSAFs provide an estimate of the uptake of chemical constituents from sediment to biological tissue by taking the lipid-normalized concentration in organisms divided by the organic carbon-normalized concentration in sediments. The BSAFs for metals are reported as:

$$\mathrm{BSAF}\left(\mathrm{kg\,sediment}/\mathrm{kg\,tissue}\right)=\frac{\mathrm{mg}/\mathrm{kg\,tissue}}{\mathrm{mg}/\mathrm{kg\,sediment}}$$

These BSAFs are based on the undepurated data, meaning that the total tissue concentrations reflect sediment retained in the gut. The BSAFs therefore may not provide an accurate representation of contaminants accumulated in tissue. However, mummichog and crab are prey species consumed whole. Therefore, the BSAFs estimated based on the undepurated results reflect the food chain impacts. The BSAFs for fish and crab tissue are presented in Tables N-14a and b, respectively. They are highly variable but all well below 1, indicating that the tissue contains lower concentrations than sediments in the corresponding areas. Thus biomagnification into tissue is not occurring from sediment.

5. CONCLUSIONS

Old Place Creek is a tidal creek located within estuarine marshes and adjacent successional southern hardwood forest. The creek is situated within the northern portion of the Arthur Kill estuary, which is heavily industrialized. Old Place Creek is follows a natural course as has not been filled or channeled, unlike many of the other tidal creeks contributing to the Arthur Kill Estuary, including South Branch Creek. Samples collected within a tributary of Old Place Creek have revealed contaminants in sediment and biota that indicate regional industrial impacts. Chemical impacts include Mercury, PCBs, PAHs, and Dioxins/Furans that exceed applicable screening criteria.

Notes:
(a) Saltwater CCC refers to Saltwater Criteria Continuous Concentration (chronic criterion) per EPA 822-Z-99-001, April 1999
(b) Saltwater CMC refers to Saltwater Criteria Maximum Concentration (acute criterion) per EPA 822-Z-99-001, April 1999
(c) Calculated using the World Health Organization (2005) Toxicity Equivalence Factors (TEFs); nondetects treated as zero
UG/L = microgram per liter
MG/L = milligram per liter
NG/L = nanogram per liter
Rejected data are not included in the descriptive statistics

TABLE N-3
METHYL MERCURY IN SURFACE WATER
Old Place Creek, Staten Island, New York

Sample ID	Total Mercury (µg/L)	Methyl Mercury (ug/L)	% Methyl Mercury of Total Mercury
Old Place Creek			
SW-W	0.0147	0.0000572	0.39%
SW-X	0.0152	0.0000535	0.35%
SW-Y	0.0164	0.0000637	0.39%
SW-Z	0.0178	0.0000912	0.51%

Notes:
µg/L - microgram per liter
