PAOC	Potential area of concern
Parsons	Parsons Environment and Infrastructure, Inc.
PBR	Permit-by-Rule
PCOC	Principal contaminant of concern
PVC	Polyvinyl chloride
qPCR	Quantitative polymerase chain reaction

Acronym	Definition / Description
RCRA	Resource Conservation and Recovery Act
SIP	Stable isotope probe
SVE	Soil vapor extraction
SVOC	Semi-volatile organic compound
SWMU	Solid waste management unit
TAL	Target Analyte List
TEA	Terminal electron acceptor
TIC	Tentatively identified compound
USEPA	United States Environmental Protection Agency
VEFR	Vacuum-enhanced fluid recovery
VOC	Volatile organic compound
Work Plan	Revised Monitored Natural Attenuation Implementation Work Plan

Units	
µg/L	Microgram(s) per liter
mg/kg	Milligram(s) per kilogram
mg/L	Milligram(s) per liter

1.0 INTRODUCTION

Parsons Environment and Infrastructure, Inc. (Parsons) has prepared this Monitored Natural Attenuation (MNA) Annual Report for the former Chevron Perth Amboy Facility (Facility) located at 1200 State Street, Perth Amboy, New Jersey (**Figure 1).** MNA was proposed as a corrective measure (CM) in the Corrective Measures Study (CMS) Final Report (Chevron 2008a), either as a stand-alone CM or in combination with other CMs, to achieve the remediation goals for organic contamination in groundwater. This MNA Annual Report updates the design, approach, and details of the MNA CM, which was approved in the 2013 Hazardous and Solid Waste Amendments (HSWA) Permit Renewal and discussed in the MNA Implementation Work Plan (IWP) submitted to the United States Environmental Protection Agency (USEPA) and New Jersey Department of Environmental Protection's (NJDEP) in September 2018 and Revised in December 2019.

MNA is the reliance on natural processes to achieve cleanup criteria. These processes act without human intervention to reduce the mass, toxicity, mobility, volume, and/or concentration of contaminants in soil and/or groundwater. These in-situ processes can be either abiotic or biological and include biodegradation, dispersion, dilution, sorption, volatilization, chemical or biological stabilization, transformation, or the destruction of contaminants. Naturally occurring biological stabilization or destruction of contaminants (also known as intrinsic bioremediation, or just bioremediation) can be a dominant process in the fate and transport of contaminants and can occur either aerobically or anaerobically. It happens when naturally occurring microorganisms consume or otherwise degrade contaminants. The ultimate goal of bioremediation is to transform the contaminants into harmless byproducts such as carbon dioxide and water. MNA requires monitoring procedures to ensure both its effectiveness and that cleanup criteria are being met within a reasonable timeframe.

This MNA Annual Report details the tasks performed as part of the implementation and monitoring of the MNA CM at the Facility. This annual report assesses the first quarter 2022 status of MNA at the Facility as it pertains to benzene. Specifically, the report summarizes available benzene-related MNA data and evaluates if MNA is functioning as expected to reduce Facility contamination. As stated in the IWP, benzene is the regulatory driver for hydrocarbons at this Facility (Chevron 2019e). This is because many other hydrocarbons are preferably targeted for attenuation by biological processes, making benzene a conservative indicator for biodegradation.

An evaluation of MNA at the Facility indicates that natural attenuation processes are reducing contaminant concentrations.

The following regulatory guidelines were considered during the MNA review:

- Resource Conservation and Recovery Act (RCRA) Corrective Action Plan Guidance (USEPA 1994).
- New Jersey Department of Environmental Protection's (NJDEP 2012a) Technical Requirements for Site Remediation (N.J.A.C.[1] 7:26E).

[1] N.J.A.C. – New Jersey Administrative Code

- Administrative Requirements for Remediation of Contaminated Sites, N.J.A.C. 7:26C (NJDEP 2012b).
- New Jersey Department of Environmental Protection's (NJDEP 2018) Ground Water Quality Standards (N.J.A.C. 7:9C).
- New Jersey Department of Environmental Protection's (NJDEP 2022) Monitored Natural Attenuation Technical Guidance.

1.1 Facility Location and Operational History

The Facility lies primarily in the industrial zone of Perth Amboy, New Jersey, occupying approximately 268 acres. It is currently divided into three yards: the Central Yard, East Yard, and Main Yard (**Figure 2**).

Historically, Barber Asphalt Company owned and operated the property beginning in 1911. In 1946, Chevron purchased the property and operated the Facility as a full-scale petroleum refinery from 1946 to 1983, producing liquefied petroleum gas, gasoline, fuel oil, and asphalt. In 1983, Chevron reduced its operations to refining asphalt while also continuing petroleum storage operations. On July 26, 2012, Chevron completed the sale of most of the Facility property to Buckeye Partners, L.P. (Buckeye). Buckeye (operating under Facility-specific entity Buckeye Perth Amboy Terminal, LLC) currently operates the Facility as a petroleum products terminal. A more detailed description of the Facility ownership and its historical operations can be found in the 2008 CMS (Chevron).

1.2 Purpose

This MNA Annual Report summarizes the updated status of MNA implementation as a CM at the Facility through first quarter of 2022. The initial 2008 CMS recommended implementation of MNA to remediate areas with groundwater benzene concentrations between 1 microgram per liter (µg/L, which is the NJDEP Ground Water Quality Standard [GWQS]) and 100 µg/L, which is the CM implementation (CMI) action level (**Table 1**). In Facility source areas with higher benzene concentrations (>100 µg/L), more active remedial activities have been implemented. However, as these active remedial processes achieve their goals of reducing benzene concentrations to below 100 µg/L, MNA either has been or will become the primary CM, as outlined in the 2008 CMS.

Within the Facility, MNA is occurring within the following solid waste management units (SWMUs) and areas of concern (AOCs) (**Figure 3**):

- SWMUs: 5, 6, 8, 10, 11B, 16, 17, 18, 20, 21, 24, 26, 29, 34, 35, 39, 40, 41, and 43
- AOCs: 8, 9A, 9B, 14, 15, 16B, 22, 23, 25, 31, 36, 39, 41, 44, and 50

It should be noted that several areas on the Facility were identified in the 2008 CMS as having exceedances of multiple principal contaminants of concern (PCOCs). The 2008 CMS proposed CMs for each contaminated media based on the individual PCOCs. Where necessary, multiple CMs were implemented in those areas to address the exceedances of PCOCs in accordance with the HSWA Permit Renewal. MNA is proposed as the final CM for each area.

1.3 Report Organization

Following this introduction, this Annual Report is organized as follows:

- Section 2 describes the MNA CM objectives and applicable regulatory requirements.
- Section 3 describes the current CSM.
- Section 4 summarizes the overall s at the Facility.
- Section 5 describes the field implementation approach and methods and the tentative, continued implementation schedule of the MNA CM for the selected SWMUs and AOCs.
- Section 6 summarizes the groundwater data.
- Section 7 describes the molecular microbiological and stable-isotope studies conducted at the Facility to provide direct evidence of MNA.
- Section 8 describes the current state of benzene plumes at the Facility.
- Section 9 summarizes the impact of in-situ chemical oxidation (ISCO) and other source control measures on MNA.
- Section 10 describes other MNA results obtained in conjunction with ISCO activities.
- Section 11 provides conclusions.
- Section 12 provides recommendations for the Facility.
- Section 13 contains references for documents cited in this report.

The report text is followed by supporting tables and figures and Appendices A through E, which contain the following additional information:

- Appendix A – Volatile Organic Compound and Semi-Volatile Organic Compound Results in Groundwater
- Appendix B – Geochemical Parameter Results in Groundwater
- Appendix C – MNA Work Plan, Monitoring Schedule Flowchart, and Well Construction Summary
- Appendix D – Molecular Biological Data
- Appendix E – Detailed Benzene Evaluation Data

2.0 TREATMENT OBJECTIVE AND REGULATORY REQUIREMENT

The following CM objectives were proposed for groundwater in the 2008 CMS for the Facility:

- Prevent exposure of humans to groundwater contaminants at concentrations above regulatory standards,
- Remediate contaminant concentrations in groundwater to below applicable regulatory standards, and
- Prevent or minimize migration of PCOC plumes.

2.1 MNA Corrective Measure Objective

As described in the 2008 CMS, benzene has been determined to be representative of all volatile organic compounds (VOCs) for the Facility. As such, benzene will be discussed in this document as an analog for all petroleum hydrocarbon VOCs present in groundwater. The media-specific cleanup goal for the MNA CM, as established in the CMS, is as follows: reduce dissolved phase benzene concentrations from less than 100 µg/L in groundwater to below the N.J.A.C 7:9:C GWQS for Class-IIA aquifers (1 µg/L benzene). When all active groundwater CMs at the Facility are complete, a Facility-wide classification exception area (CEA) will be established for groundwater with constituents of concern (COCs) exceeding GWQSs (NJDEP 2018).

3.0 CONCEPTUAL SITE MODEL

3.1 Topography

The topography at the Facility has predominantly been shaped by construction activities performed during site development, such as cut and fill grading. The northern, central, and eastern portions of the Facility are relatively flat. Berms (generally 6 to 8 feet high) have been constructed around each petroleum storage tank for spill containment. Sheet piles have been installed to stabilize the fill zones along stretches of the Facility adjacent to the Arthur Kill to the east. The elevation of the ground surface at the Facility generally varies from 2 to 25 feet National Geodetic Vertical Datum of 1929 (NGVD29) in the Main Yard, 2 to 27 feet NGVD29 in the East Yard, and 12 to 45 feet NGVD29 in the Central Yard (**Figure 4**).

3.2 Geology

The general stratigraphy of the Facility consists of six major units overlying the bedrock, including:

- Fill
- Organic clay and peat (Clay Horizon A)
- Glacial till and outwash (till)
- Three members of the Raritan Formation
    - Woodbridge Clay (Clay Horizon B)
    - Farrington Sand (Sand Horizon B)
    - Raritan Fire Clay (Clay Horizon C)

A more detailed description of these units is provided in Section 1.4.1 of the 2008 CMS.

The fill contains varying amounts of sands, silts, and clay. It also contains intermittent lenses of fly ash, catalyst beads and construction debris, which are usually found in the Main Yard and East Yard of the Facility. The fill and Clay Horizon A at the Facility are briefly described below.

- The thickness of the fill varies from 7 to 19 feet in the Central Yard. Beneath the fill is Clay Horizon A, which varies from 3 to 19 feet thick. Sporadic and discontinuous layers of till have been observed within Clay Horizon A.
- The thickness of the fill varies from 4 to 20 feet in the East Yard. Beneath the fill is Clay Horizon A, which varies from less than 1 to 14 feet thick. Clay Horizon A is absent at times, and the fill is observed overlying the till in the northern portion of East Yard.
- The fill varies from 3 to 15 feet thick in the Main Yard. Beneath the fill layer is a discontinuous Clay Horizon A ranging from 1 to 12 feet thick. The fill overlays till where Clay Horizon A is absent.

3.3 Hydrogeology

3.3.1 Shallow Groundwater

Shallow groundwater at the Facility is mainly observed in the unconfined fill, perched on Clay Horizon A, and in till. A semi-annual groundwater gauging program is currently in place to monitor groundwater levels at the Facility. **Figure 5** depicts the fourth quarter (4Q) 2021 groundwater elevation contours for shallow groundwater.

The shallow groundwater flow direction was generally to the northeast in the Main Yard, to the northeast in the East Yard, and to the east to southeast in the Central Yard. The hydraulic gradients measured across the Main Yard, East Yard and Central Yard generally ranged from 0.001 to 0.05 foot per foot.

3.3.2 Deep Groundwater

Chevron is currently monitoring the hydrogeology beneath the fill and Clay Horizon A. Deep monitoring wells and piezometers are primarily screened in the till (i.e., first native water-bearing zone [deep groundwater] beneath the fill and Clay Horizon A).

Figure 6 depicts the 4Q 2021 groundwater elevation contours for deep groundwater. Overall, the groundwater flow direction followed regional projections, east-northeast toward the Woodbridge Creek and the Arthur Kill. The horizontal gradients ranged from 0.0005 to 0.008 foot per foot in the Main Yard, from 0.006 to 0.01 foot per foot in the East Yard, and from 0.006 to 0.026 foot per foot in the Central Yard.

3.4 Nature and Extent of Contamination

The sources of organic contamination in soil and groundwater at the Facility are primarily related to tetraethyl lead burial areas, historical waste management practices, and operational and petroleum storage areas. Currently, the primary source of groundwater contamination is light nonaqueous phase liquid (LNAPL) and hydrocarbons sorbed to soil. Known source areas were the target of CMI activity, as most recently reported in the First Quarter 2022 Progress Report for the Hazardous and Solid Waste Amendment Permit (Chevron 2022a).

3.4.1 LNAPL Impacts

LNAPL has historically been observed at 22 areas in the Facility. The LNAPL observed is weathered petroleum, found at relatively shallow depths (less than 10 feet below ground surface [bgs]) and is relatively immobile in the subsurface. LNAPL is typically found within the more permeable lenses and layers that were placed during various periods of filling and are not continuous. Many of the lenses are located below the water table. The extent of LNAPL impacts have been delineated. The 4Q 2021 data are presented on **Figure 7**, which also compares the footprint of current LNAPL to historical, known LNAPL areas. The LNAPL at these historical areas have been removed or reduced through a variety of CMs to the current LNAPL footprints.

In 4Q 2021, LNAPL was measurable in seven of the historically identified 22 LNAPL areas at the Facility. Ongoing LNAPL recovery measures (LRMs) are occurring in 11 LNAPL areas,

including four areas where LNAPL was not detected in 4Q 2021 (SWMU 40, AOC 25, AOC 31, and EY4a). Of the remaining 11 areas, five are being monitored for LNAPL with no LRMs. In six of the areas where LRMs are no longer occurring, there are approved or pending requests for no further action (NFA) determinations. As of 4Q 2021, at least 4,432 gallons of LNAPL have been recovered through LRMs (Chevron 2022a). In general, remaining LNAPL is highly weathered, resulting in a viscous material with limited remaining soluble constituents (Chevron 2008a).

In the Main Yard, measurable LNAPL was detected in nine monitoring wells during the 4Q 2021 gauging event. LNAPL was measured in:

- MW-339: This well is in the NF2 LNAPL area in the northwestern corner of the Main Yard. A vacuum truck was used to remove LNAPL three times from monitoring well MW-339 in 4Q 2021.
- MW-0059, MW-543R, and MW-544: These wells are in the SWMU 43 area in the northern portion of the Main Yard. The SWMU 43 area underwent active remediation during 4Q 2020, and LNAPL continues to be removed as needed using absorbent socks.
- MW-0072: This well is in the NF3 LNAPL area in the central portion of the Main Yard near SWMU 35. LNAPL was removed from MW-0072 as needed using absorbent socks.
- MW-274, MW-557, and MW-558: These wells are in the AOC 8-NF6 area in the southeastern portion of the Main Yard. Three rounds of vacuum-enhanced fluid recovery (VEFR) events were performed at MW-557 and MW-558 in 4Q 2021, removing groundwater and LNAPL when observed.
- PZ-0012: This well is in the AOC 19 LNAPL area in the southeastern portion of the Main Yard. Three rounds of VEFR events were performed at PZ-0012 in 4Q 2021, removing groundwater and LNAPL when observed.

In the East Yard, measurable LNAPL was detected in two monitoring wells during the 4Q 2021 gauging event:

- MW-306: This well is in the Potential Area of Concern (PAOC 15) area in the eastern portion of the East Yard. Two rounds of VEFR events were performed at MW-306 in 4Q 2021, removing groundwater and LNAPL when observed.
- MW-0051: This well is in SWMU 42, west of Tank 750, in the western portion of the East Yard.

No measurable LNAPL was detected in the Central Yard during 4Q 2021.

3.4.2 Soil Benzene Contamination

Results of historical investigations were used to evaluate the extent of soil benzene impacts above 13 milligrams per kilogram (mg/kg). It should be noted that 13 mg/kg is the CMI action limit for benzene in soil. COCs in soil are primarily found in the fill materials at varying depths near waste management areas or operational areas. The fill material is generally composed of low permeability silts and clays with some discontinuous lenses of sand. Across most of these areas, the fill material is underlain by a naturally occurring layer of low permeability clay (Clay

Horizon A) or a glacial till composed of silts and clay with some sand lenses (Chevron 2008a). Historically, the depth of benzene contamination exceeding 13 mg/kg generally ranged from 1.5 to 14.5 feet bgs in the Main Yard, 1.5 to 12 feet bgs in the East Yard, and 1 to 16 feet bgs in the Central Yard.

ISCO has been the primary remedy to address benzene-impacted soils. However, some benzene-impacted soils overlapped with areas that were already being excavated as part of CMs to address other COCs (such as metals). As of August 2020, Facility soil with benzene impacts above 13 mg/kg have been excavated in several areas of the Facility and disposed in the on-site Corrective Action Management Unit (CAMU). Specifically, excavation was completed in 11 areas within the Main Yard (AOC 9A, AOC 15, AOC 23, AOC 41, and AOC 50 and SWMU 6, SWMU 16, SWMU 17, SWMU 18, SWMU 35, and SWMU 40). Benzene impacted soil was excavated within six areas in the East Yard (AOC 14, AOC 16EY1, AOC 26, AOC 37, AOC 38, and AOC 39). In the Central Yard, excavation of benzene impacts was performed in one area (AOC 22). ISCO injections were completed in AOC 31, SWMU 8, and SWMU 10 in the East Yard and AOC 44 in the Main Yard. ISCO soil mixing was conducted in AOC 16EY1 and AOC 39 in the East Yard, AOC 15, SWMU 6, SWMU 16, SWMU 24, SWMU 40, SWMU 41, and SWMU 43 in the Main Yard. Details of each of these remedial actions were submitted in separate documents.

3.5 Potential Receptors

Potential receptors to benzene-impacted groundwater from the Facility are discussed in the sections below.

3.5.1 Groundwater

In New Jersey, Class II groundwater is considered suitable for the provision of potable water with conventional water supply treatment. NJDEP has classified the groundwater in the Perth Amboy area as Class IIA, a potable water supply. However, groundwater quality in the uppermost water-bearing unit is degraded by various industrial activities and stormwater runoff from streets in this urban area. Near the Facility, the Farrington Aquifer outcrops along Woodbridge Creek. Historical pumping of the Farrington Aquifer caused saltwater intrusion as the saline waters of Woodbridge Creek were drawn into the recharge area of the aquifer. As documented in N.J.A.C. 7:9, Subchapter 6, which covers GWQS, the Farrington Aquifer along the banks of Woodbridge Creek at and near the Facility is designated as Class IIIB groundwater, which is not suitable for conversion to potable uses. Groundwater is not used as a source of water supply within at least two miles of the Facility, because historical pumping from the Farrington Sand has resulted in nearby saltwater encroachment.

The northern portion of Main Yard consists of tidal salt marsh wetlands (also known as North Field Basin [NFB] Wetlands). The surface water bodies, including the Arthur Kill and Woodbridge Creek, are located along the northern and eastern property boundaries. Tidally influenced groundwater level fluctuations and saltwater intrusion into the shallow water-bearing zone have been observed and documented in the areas near Woodbridge Creek. Data from wells in the NFB area have shown a tidally related groundwater elevation fluctuation of up to 1.5 feet. In contrast, the extent of tidal influence has not been fully clarified for monitoring

wells in the East Yard Basin area. This potential tidal influence in the East Yard may subsequently be affected by bulkheads that have been placed along the Arthur Kill (Chevron 2008a).

3.5.2 Human Health

Several structures within the Facility are occupied. A vapor intrusion evaluation was conducted for the on-site structures. It was concluded that the vapor intrusion exposure pathway does not pose a significant risk to potential receptors at the on-site structures (Chevron 2008a; Chevron 2016a).

4.0 CORRECTIVE MEASURE TECHNOLOGY SUMMARY

4.1 Natural Attenuation

USEPA defines natural attenuation as the biodegradation, diffusion, dilution, sorption, volatilization, and/or chemical and biochemical stabilization of contaminants to effectively reduce contaminant toxicity, mobility, or volume to levels that are protective of human health and the environment (USEPA 1999). Typically, MNA is used in conjunction with active remediation. At this Facility, it is implemented as a CM for groundwater with organic contaminant concentrations ranging from 1 to 100 µg/L. Above this concentration, active remediation CMs, such as ISCO, are employed to reduce concentrations. Once benzene concentrations are within this range, however, MNA becomes the primary remedy.

Geochemical data from the monitoring wells located in the Facility's Main Yard, East Yard and Central Yard were analyzed. Approximately 500 existing wells throughout these yards were sampled and analyzed for groundwater geochemical (MNA) parameters between 2012 and first quarter (Q1) 2022. These data were analyzed to confirm that MNA will effectively reduce low levels of organic contamination in the groundwater.

4.2 Source Control

A key component of successful MNA is source control, either through containment, removal, or treatment, to prevent continuing contributions to the dissolved phase. Source control was conducted in select areas of the Facility through the implementation of ISCO or other CM remedies, as described in Section 5.0 below. Progress with CM treatments will continue to be reported in CM-specific documents and communications, as opposed to within this MNA-specific document.

As described in detail within this report, a comparison of benzene concentrations over the last 10+ years shows that areas of elevated concentrations have significantly reduced in size. The remaining areas of low concentration are prime targets for natural attenuation (including biodegradation), and over time will decrease in size as the indigenous microbial population consumes Facility constituents. This suggests that the existing groundwater plumes that still have elevated benzene concentrations are stable to decreasing and have the potential to attenuate after adequate source reduction is accomplished.

4.3 Institutional Controls

Institutional controls may be appropriate to protect human health and the environment in areas where soil and groundwater contaminant concentrations will exceed applicable criteria/standards following the application of a CM. Institutional controls are non-engineering measures, such as administrative and/or legal controls, that help minimize the potential for human exposure to contamination by limiting the land use in the area to which it was applied. Institutional controls include deed restrictions for impacted soil and CEAs for impacted groundwater. CEAs are established to provide notice that the groundwater quality standards for an aquifer classification either are not, or will not, be met in a localized area due to natural

water quality or anthropogenic influences. Designated aquifer uses are suspended in the affected area for the term of the CEA to ensure that the uses of the aquifer are restricted until the GWQSs are achieved, thereby limiting the potential for human exposure.

N.J.A.C. 7:9-6 (New Jersey GWQS) provides the basis for the protection of groundwater quality through the establishment of constituent standards for groundwater pollutants. The standards impact all site remediation cases where groundwater contamination exceeds the standards applicable to the groundwater classification area in which the site is located. Except for a limited area along the banks of Woodbridge Creek, the Facility is in a Class-IIA aquifer. Groundwater quality standards are summarized in **Table 1**.

5.0 SUMMARY OF FIELD ACTIVITIES

The CMI work at the Facility commenced in 2012. As of September 2020, all requirements for remedial construction completion for soil within 49 AOCs and 45 SWMUs have been met. The remaining AOCs and SWMUs were either approved for NFA or were associated with the West Yard/Amboy Field or North Field. CMs completed at the Facility included the following:

- ISCO injections
- ISCO soil mixing
- Soil excavation and CAMU internment
- In-situ stabilization (ISS)/ex-situ stabilization (ESS) soil mixing
- In-situ chemical fixation (ISCF)
- Permeable reactive barrier wall installations
- Arsenic cap installations
- Enhanced in-situ bioremediation (EISB) injections
- Electric resistance heating system installation
- Biosparge system installations
- Air sparge/soil vapor extraction (SVE) system installation
- SWMU 43 cap installation
- Final CAMU closure
- MNA monitoring system for groundwater
- Filing of deed notices

Lead in soil with toxicity characteristic leaching procedure lead levels greater than 5 milligrams per liter (mg/L) and total organic lead concentrations greater than 2 mg/kg has been addressed through excavation, ESS, and disposal in the Facility's CAMU. ISS was completed for toxicity characteristic leaching procedure lead levels less than 5 mg/L and lead levels greater than 800 mg/kg in soil. An ISS/ESS CM was conducted in five AOCs and 13 SWMUs within the Main Yard, three AOCs and three SWMUs within the East Yard, and two SWMUs within the Central Yard.

Benzene concentrations in groundwater greater than 100 µg/L were addressed by ISCO injections in two AOCs within the Main Yard and two AOCs and two SWMUs within the East Yard. Excavation and soil mixing of persulfate and calcium hydroxide was used to address benzene impacts in three AOCs and 11 SWMUs within the Main Yard, two AOCs within the East Yard, and two AOCs and one SWMU within the Central Yard. An air sparge/SVE system was installed within AOC 8 in the Main Yard to remediate benzene impacts in soil and groundwater. The installation and operation of biosparge systems occurred in AOC 31 and AOC 50 to address benzene, and these systems are still operating.

Arsenic concentrations greater than 20 mg/kg in surface soil were addressed through containment consisting of a cap constructed using material similar to the existing ground surface or an existing surface that serves as a cap. This method was used to address arsenic impacts in surficial soil in one AOC and five SWMUs within the Main Yard, eight AOCs and one SWMU within the East Yard, and one SWMU within the Central Yard. Arsenic impacts in groundwater greater than 60 ug/L were addressed by ISCF permeable reactive barrier wall installations in AOC 14/SWMU 26 and AOC 45/46 in the East Yard.

Chlorinated VOCs were identified in AOC 36 in the Central Yard. EISB was used to address these impacts in groundwater. EISB was also used to target benzene in AOC 44 in the Main Yard. Electric resistance heating was conducted in AOC 31 in the East Yard to address LNAPL and benzene impacts in soil and groundwater.

5.1 MNA Monitoring Schedule

The below MNA monitoring schedule has been developed in accordance with the NJDEP Monitored Natural Attenuation Technical Guidance (NJDEP 2022). A minimum of eight rounds of groundwater sampling will typically be needed to demonstrate the applicability and occurrence of MNA. These events will help define seasonal variation in contaminant concentrations, geochemical parameters, and groundwater flow patterns. It should be noted that while historical site investigation or remedial investigation data can be used to fulfill this sampling requirement, the data must represent post-remedial (CMI) conditions in areas where source removal has occurred.

Sampling of Facility monitoring wells in the MNA plan will continue until MNA has been demonstrated for the minimum prescribed eight events discussed above. Once MNA has been demonstrated, and if COC concentrations continue to exist above the NJDEP GWQS, an application for a remedial action permit for groundwater and a proposed CEA will be submitted (NJDEP 2022. MNA evaluation will continue until the NJDEP issues the remedial action permit for groundwater. However, to use Facility resources efficiently, the frequency of monitoring will be reduced. Once the remedial action permit for groundwater is issued, groundwater will be sampled and MNA will be evaluated in accordance with the permit.

A well will be transitioned to a biennial monitoring schedule in accordance with the approved MNA IWP (Chevron 2019e) when two conditions are met:

- The required eight rounds of benzene MNA monitoring have been completed.
- Benzene concentrations remain between 1 and 100 µg/L.

The monitoring events will be scheduled to target the time of year expected to exhibit the highest levels of contamination based on the results of historical groundwater data. Monitoring wells that exhibit concentrations less than or equal to 10 µg/L during a biennial sampling event will be sampled annually thereafter so that achievement of GWQS can be rapidly documented and site closure facilitated. This will continue as long as MNA is demonstrated and until benzene concentrations reduce to below 1 µg/L. If benzene concentrations remain at or below 1 µg/L for two consecutive monitoring events, then the well will be considered for removal from the monitoring program using the criteria listed below.

A monitoring location may be removed from the monitoring program only if the above-mentioned benzene concentration criteria are first met. Then, an evaluation will occur to determine if the well location is critical for determining MNA, such as being a key background, downgradient, or sentinel location. If it is critical, then the well will continue to be monitored in alignment with the approach described above. Furthermore, if other COCs are present in the monitoring well's groundwater above their respective GWQSs, then the well will continue to be monitored on a frequency determined by these non-benzene COCs. However, the monitoring well will be removed from the Facility's monitoring plan if the well is:

- Not critical (as defined above), and
- Does not report other, non-benzene, COCs to be present at concentrations above their respective GWQSs, and
- Reports benzene concentrations that have remained at or below 1 µg/L for two consecutive monitoring events.

The monitoring wells included in the sampling plan is shown in **Appendix C**. This plan lists wells by yard that will be sampled in accordance with the above-mentioned sampling plan. A flowchart outlining this methodology is also outlined in **Appendix C**. Groundwater samples will analyzed for VOCs plus tentatively identified compounds (TICs), semi-volatile organic compounds (SVOCs) plus TICs, MNA parameters, and groundwater stabilization readings. If benzene concentrations remain above the GWQS of 1 µg/L but SVOC results were detected below their respective GWQS for two consecutive monitoring events, SVOCs will not be analyzed.

The current MNA sampling and monitoring program was initiated in the second quarter of 2021. The number of MNA sampling events is being evaluated to determine when the above-discussed required eight rounds has been completed. For wells sampled as part of ISCO long-term monitoring, much of this sampling has already been completed or is currently being completed as part of post-implementation sampling. It should be noted that once ISCO long-term monitoring has been completed and post-remedial conditions achieved, monitoring wells will be transitioned to the MNA monitoring plan as proposed in the plan described above. MNA Monitoring Well Construction Details

Construction details for monitoring wells that are currently on the Facility and are part of the MNA monitoring program can be found in **Appendix C**.

5.2 Deviations from Monitored Natural Attenuation Implementation Work Plan

5.2.1 Deviations from Proposed Sampling Plan

The Revised Monitored Natural Attenuation Implementation Work Plan (Work Plan) (Chevron 2019e) proposed groundwater monitoring locations and frequencies. Monitoring wells have been added and removed from the original plan based on current benzene concentrations.

The monitoring wells listed below were removed from the MNA plan since they are currently being evaluated as part of a CMI performance monitoring sampling plan:

- Main Yard – MW-0029 (SWMU 43), MW-0032 (SWMU 24), MW-118, MW-125 (SWMU 6), MW-158 (AOC 50), MW-233, MW 338 (AOC 44) MW-263, MW 396, MW-397 (SWMU 35), and MW-264, MW-265 (AOC 8)
- East Yard – MP-01R, MW-329R, MW-504 (SWMU 8), MW-317R, MW-331, MW-449, MW-455 (AOC 31), and MW-296, MW-465 (AOC 16 EY1)

The following monitoring wells were removed from the MNA monitoring plan because benzene concentrations in groundwater are consistently below the GQWS of 1 µg/L, and these locations are no longer needed for background or downgradient impact monitoring.

- Central Yard – MW-183, MW-364, MW-513, MW-514, MW-515, MW-518, and MW-531 (all located within AOC 22/36)
- East Yard – MW-476, MW-500, MW-525, and MW-526 (all within AOC 31)

The following monitoring wells were removed from the MNA sampling plan because they either were abandoned or are now inaccessible:

- Main Yard – MW-20, MW-259, and MW-324
- East Yard – MW-115R

Once remedy effectiveness has been demonstrated for a monitoring well, it will be transitioned into the MNA program.

5.2.2 Deviations in Sampling Procedure

The guidelines for the content of this MNA Report were provided in Section 7.2 of the revised and approved Monitored Natural Attenuation Implementation Work Plan (Chevron 2019e). Pursuant to these guidelines, below is a discussion of a noted deviation from the approved IWP strategy for groundwater sampling.

Section 6.2 of the approved IWP discussed the groundwater sample collection methods to be used as part of the MNA CM. The approved IWP specified that, per the NJDEP Field Sampling Procedures Manual (NJDEP 2005), inorganic MNA parameters (target analyzed list [TAL] metals and ferrous iron) will be collected via low-flow sampling. However, other MNA parameters (nitrate, nitrite, sulfate, sulfide, methane, ethane, total Kjeldahl nitrogen, phosphorus, and total organic carbon) will be collected with a bottom-fill Teflon® bailer after a volume average purge.

As discussed in Appendix D of the USEPA/NJDEP approved Field Sampling and Analysis Plan/Quality Assurance Project Plan (FSAP-QAPP) (Chevron 2019b), all CAMU groundwater samples will be collected through the tubing from the bladder pump. To standardize all sampling methods and improve consistency in sample quality, low-flow bladder pump sampling was adopted for all Facility groundwater sample collection at the time that the MNA CM was initiated in 2021. Per chapter 6E, Section 6.9.2 of the NJDEP Field Sampling Procedures Manual (NJDEP 2005), the method of low-flow purging and sampling with a bladder pump is acceptable for all contaminants.

6.0 GROUNDWATER MNA-RELATED DATA OBTAINED

Biological natural attenuation occurs when indigenous microorganisms degrade (consume) contaminants either aerobically (in the presence of oxygen) or anaerobically (in the absence of oxygen). Some contaminants, such as benzene, can also be fully mineralized to carbon dioxide.

The three, typically-accepted lines of evidence for assessing the efficiency of natural attenuation are (ASTM, 2022):

- Groundwater chemistry data showing that geochemical conditions are suitable for natural attenuation and the rate at which natural attenuation processes are active (addressed in this section of the report.
- Data demonstrating the occurrence of a natural attenuation process, typically used to demonstrate that biodegradation is occurring (USEPA 1999). These data can take many forms. Indirect biogeochemical data that are used to monitor bioattenuation can include evidence of depletion of electron acceptors and donors, increased metabolic byproduct concentrations, decreased parent compound concentrations, and increased daughter compound concentrations (Weidemeier et al. 1996; Weidemeier et al. 1999). These are addressed in this section. However, modern direct methods also exist for evaluating the biology associated with bioattenuation, and these are discussed in Section 7.
- Plume stabilization and/or loss of contaminant mass over time are addressed in Section 8.

Section 6.1 provides an overview of groundwater geochemical parameters used to indirectly assess if biological compound attenuation is occurring. This includes a discussion on the data needed to show that Facility conditions are suitable for natural attenuation. Section 6.2 discusses the observed groundwater geochemistry results that are related to MNA.

6.1 Overview of MNA-Associated Data

As stated above, the first line of evidence for assessing the efficiency of natural attenuation involves an evaluation of site geochemistry. For this Facility, this includes an initial evaluation of benzene concentrations alongside an evaluation of those MNA geochemical parameters associated with benzene bioattenuation. To evaluate the potential for MNA, related geochemical data from approximately 500 existing monitoring wells located in the Main Yard, East Yard and Central Yard and groundwater geochemistry were analyzed. The dataset evaluated for MNA covered the period from 2012 to the first quarter 2022 (**Appendices A** and **B**). These data were analyzed to evaluate historical and current biogeochemical conditions, and to determine if MNA is occurring.

MNA parameters such as total alkalinity, pH, oxidation reduction potential (ORP), sulfate, sulfide, dissolved (ferrous) iron, total iron, dissolved oxygen (DO), and nitrates provide useful, if indirect, information on the biodegradation potential of the contaminated media. This process has been summarized in many publications including, but not limited to Talley (2006), Weidemeier et al. (1999), and Young and Mulligan (2003).

There are several field-tested MNA parameters. For example, microbes have minimum and maximum tolerances and optimum levels for both temperature and pH. The ORP value is a measure of electrical current in groundwater, which reflects how oxygenated or reduced an environment is. The ORP value will provide information about which form of microbial metabolism is likely to dominate the area being tested. An increase in alkalinity, which generally reflects the amount of bicarbonate in groundwater, is an indication of the biodegradation of organics. As such, alkalinity can provide indirect insights into whether site contaminants are being fully mineralized, and thus can allow for qualitative comparisons between locations or timepoints.

Every microbe contains a chemical that is referred to as the terminal electron acceptor (TEA). As this TEA scavenges and binds up free electrons, it is transformed from an oxidized form into a reduced form. Depending on the type of TEA used, different amounts of energy are ultimately produced for the microbe. However, a microbial community will metabolize (consume) organic material (including hydrocarbons) in a way that will allow for the greatest resulting energy generation to occur under site conditions. As such, there is a sequential preference for the form of metabolism to be used.

If oxygen is present, aerobic bacteria in a community will conduct aerobic metabolism, generating the most energy (per unit of organic material) of the metabolic processes. If oxygen is not present, or has been consumed, then the active microbial community members will transition to those able to use other electron acceptors, beginning with nitrate. Once nitrate concentrations become depleted, iron-reducing bacteria will dominate the community. As ferric iron concentrations become low, this community will subsequently transition to one dominated by sulfate-reducing bacteria, if sulfate is present. If sulfate becomes depleted, the microbial community will transition to the lowest-energy-producing metabolism of methanogenesis.

Summary of the Sequential Utilization of TEAs in an Environment

Metabolic Degradation Process Name	TEA Utilized	Product of the Reduction of the TEA	Type of Microbe Performing This Metabolism
Aerobic	Oxygen	Water	Aerobes
Nitrate Reduction	Nitrate	Nitrite	Nitrate Reducers
Iron Reduction	Ferric Iron [Fe (III)]	Ferrous Iron [Fe (II)]	Iron Reducers
Sulfate Reduction	Sulfate	Sulfide	Sulfate Reducing Bacteria
Methanogenesis	Carbon Dioxide	Methane	Methanogens

Because of this sequential utilization of TEAs, the resulting groundwater geochemistry can develop a “fingerprint” of biological natural attenuation. Assuming that nutrients (including appropriate TEAs) are not being replenished in the environment fast enough to overcome utilization rates, the above-described process of transitioning from one dominant metabolism to another will occur. Eventually, the environment will reach an equilibrium in which higher concentrations of organic matter will correlate with more reduced environmental conditions.

Thus, in the case of a hydrocarbon plume (for example), the core of the plume will be more reduced relative to the periphery of the plume.

The most impacted core of a hydrocarbon plume may be under the influence of sulfate-reducing to methanogenic conditions. Moving away from this core toward the periphery where hydrocarbon concentrations are lower, conditions often become dominated by iron-reducing conditions, and then nitrate-reducing conditions. If oxygen is present at the plume periphery, aerobic conditions will dominate. This classic fingerprint of more reduced forms of metabolisms dominating in areas of higher hydrocarbon concentrations is a hallmark of biological contaminant degradation.

It is worth noting that, although an overall microbial community can be dominated by a metabolic process, multiple TEA processes can occur simultaneously in a location. Additionally, micro-environments as well as stratified TEA processes with depth can exist. Finally, TEA processes can be dynamic. As such, this classic fingerprint can sometimes be less clear in some locations in comparison to others.

These TEA processes are at work on both naturally occurring organic matter (such as decomposing plant material) and organic contaminants (such as hydrocarbons). This underscores the importance of trying to find upgradient or background groundwater to compare against the geochemical parameters found within the core and periphery of a contaminant plume. However, this ideal situation may not be available at all locations, and less-ideal monitoring wells may have to be accepted as a representation of background conditions. Additionally, the microbial degradation of non-contaminant material possibly found in the subsurface of a site is important to consider because byproducts such as methane can be generated from this innocuous material. Methane is a gas and therefore travels easily from one location to another via preferential pathways. These include along subsurface features such as buried utilities and monitoring well casings that may have perforated a methanogenic pocket. Thus, methane generated in one location can easily travel, and be detected, in a very different location. Together, these variables underscore the importance of looking at multiple lines of evidence when evaluating MNA.

Because this Facility is subdivided into three main areas: the Central Yard, Main Yard, and East Yard with varying historical uses, geography, and geology, it is appropriate to look at MNA within each subdivision. Although historical trends dating back to 2012 are assessed for this report, unless otherwise noted, all data to be discussed were reported for 2020 through 2022. Regarding benzene concentrations, the discussion below follows the trend established by Facility maps: areas of higher benzene concentration will be defined as those exceeding 100 µg/L, and areas of lower concentration will be defined as those having benzene concentrations ranging from 1 through 100 µg/L. This is based on the CMI action level of 100 µg/L. However, any exceptions to these categories are noted in the data discussion in this section.

In addition to considering historical benzene concentration data, wells chosen for discussion in this report also needed to have enough recent MNA geochemistry data for a proper assessment to occur.

Finally, for the purposes of this report, monitoring wells described as “background” are those where benzene concentrations have typically been detected at concentrations below 1 µg/L

and have available and recent MNA data for a proper assessment to be made. At a Facility such as this, it is common to have no available monitoring wells that are truly nondetect for COCs. It is also not unusual to have limited upgradient wells available for assessment because property lines and groundwater flow patterns are complicated by the presence of above-ground and subsurface structures and tidal fluctuations. In these situations, monitoring wells that consistently have low COC concentrations can serve as baseline wells, providing the best available interpretation of conditions away from the bulk of the plume.

For all three Facility yards, benzene and other groundwater VOC data are provided in **Appendix A**. Groundwater biogeochemistry parameters, including the MNA parameter data discussed above, is provided in **Appendix B**.

6.2 Groundwater Geochemistry Sampling Results

An evaluation of groundwater geochemistry and biogeochemistry was presented in the 2019 Work Plan (Parsons 2019e). That data has been updated as reflected below to include data generated since 2020. All of the data relevant to MNA is being evaluated to determine whether natural attenuation (focusing on benzene) is occurring at the Facility.

A much more complete picture of MNA can be produced when general benzene trends and data are coupled with available MNA data. That analysis is provided below. A more detailed evaluation of benzene-specific trends, including using statistical analyses, is reported in Section 8.

Finally, the groundwater benzene and MNA parameter concentration data discussed below are detailed in **Appendix A**. Groundwater field parameter data discussed below, such as DO concentrations and ORP values, are detailed in **Appendix B**.

6.2.1 Central Yard

The Central Yard is the most inland of the three yards, having no waterfront access.

In impacted locations, concentrations of benzene in Central Yard monitoring wells have generally trended downward from 2017 to 2022 (**Figures 8** through **10**). Benzene concentrations were less than 100 µg/L in 2020 and 2021 in Central Yard monitoring wells. The single exception to this was MW-102R (190 µg/L in December 2021). This monitoring well has historically reported benzene concentrations that are higher than what was detected in surrounding monitoring wells, such as in 2008. However, benzene concentrations have also been reported under 100 µg/L multiple times in this location since the well was installed in 2019.

Monitoring wells MW-167 and MW-169R are near AOC 36, in the southern tip of the Central Yard and downgradient of the southern Central Yard plume. MW-167 has been non-detectable for benzene since at least 2010 and benzene concentrations in MW-169R have been below the GWQS for several years. As such, they are good representatives of background conditions for the southern region of the Central Yard. Nitrate concentrations are below detectable levels in both monitoring wells. Ferrous iron concentrations range between 490 and 7,390 µg/L and sulfate concentrations range from 14,000 to 32,000 µg/L. An evaluation of DO concentrations

and ORP values supports that these two monitoring wells are under the influence of microaerophilic to nitrate-reducing conditions.

Benzene concentrations in MW-533 range between 3.1 and 8 µg/L. Nitrate is depleted in this monitoring well, and ferrous iron concentrations are between 340 and 1,100 µg/L. Sulfate concentrations range between 98,000 and 110,000 µg/L. Similar to the above-mentioned background wells, the DO concentrations and ORP values confirm that MW-533 is also primarily under microaerophilic to nitrate-reducing conditions.

Benzene is detected in higher concentrations in MW-386 and MW-369, ranging from 1.2 to 47 µg/L. Nitrate is depleted in both monitoring wells, and ferrous iron concentrations range between 41,000 and 48,000 µg/L. Sulfate concentrations range between 51,000 and 96,000 µg/L. Given the higher concentration of benzene, the typical fingerprint for benzene MNA would predict that these monitoring wells would be dominated by more reduced subsurface conditions. However, DO concentrations and ORP values confirm that these two monitoring wells are instead dominated by aerobic conditions.

As discussed above, benzene concentrations in MW-102R have been historically reported at higher concentrations than found in surrounding monitoring wells. As with other discussed monitoring wells in the Central Yard, nitrate is depleted in this location. Ferrous iron concentrations range from 1,100 to 32,000 µg/L and sulfate concentrations range from 11,000 to 270,000 µg/L. Available DO concentrations and ORP values suggest that this monitoring wells is primarily under the influence of nitrate -reducing to occasionally iron-reducing conditions.

Thus, groundwater geochemistry parameters in and around AOC 36 do not necessarily follow the typical pattern expected for an area under the influence of natural attenuation for hydrocarbons. This typical pattern would reflect more reduced conditions as hydrocarbon concentrations increase (such as near the core of the plume, which would be MW-102R for benzene), and less-reduced conditions where hydrocarbon concentrations are lower (such as at the plume periphery). These environmental conditions are determined by looking at concentrations of groundwater constituents that include nitrate, ferrous iron, and sulfate in addition to DO and ORP values. This pattern generally appears in the 2016 and 2017 data for AOC 36 (Chevron 2019c). However, multiple EISB injections were conducted in the AOC 36 area in 2018. The 2018 EISB injections were composed of a mixture of both a slow- and fast-release carbon source that would drive the subsurface environment to be strongly anaerobic. The goal of these injections was to artificially alter the subsurface environment to facilitate the biodegradation of chlorinated compounds in groundwater (Chevron 2022b). These targeted chlorinated compounds are found near to, if not co-located with, benzene. It is therefore not surprising that this traditional fingerprint for hydrocarbon bioattenuation (where redox conditions are inversely related to hydrocarbon concentrations) is no longer clearly evident in the 2020 to 2022 data. But this does not mean that benzene bioattenuation is not occurring. Instead, the traditional natural attenuation fingerprint has just been masked by the 2018 EISB treatment injections. The topic of AOC 36 is addressed in detail in the Discharge to Groundwater/Permit-by-Rule Monitoring Report for Enhanced In-Situ Bioremediation (EISB), Area of Concern 36, MW216/MW220 and MW-367 Areas, submitted to USEPA in September 2019 (Chevron 2019c).

The second major area of interest is in the northwest corner of the Central Yard. Background conditions in the middle to northern portion of the Central Yard are dominated by nitrate reducing to iron-reducing conditions, as demonstrated in MW-416 (Former PAOC 82) and MW-417 (Former PAOC 82). In these wells, nitrate was continuously below 40 µg/L, indicating that this nutrient and TEA were consistently depleted. However, ferrous iron concentrations were robust, ranging from 88,000 to 1,110,000 µg/L in 2020 and 2021. Sulfate concentrations were also elevated in these two monitoring wells, ranging from 290,000 to 330,000 µg/L in 2020 and 2021. Available ORP and DO values also remained elevated in these two background wells. Together, these data suggest that these two wells were strongly under the influence of nitrate-reducing to iron-reducing conditions.

MW-0054R and MW-0055R have available data for assessing MNA in this area of low benzene concentrations. As with the above-described periphery monitoring wells, nitrate is generally depleted. Sulfate concentrations are relatively high, ranging from 72,000 µg/L to 130,00 µg/L. Ferrous iron concentrations in these two monitoring wells are typically increased compared to background concentrations. This suggests that this region of the Central Yard is primarily dominated by nitrate-reducing to ferrous-iron conditions. This is supported by available DO concentration and ORP value data.

One monitoring well in this region, MW-0056R, has reported higher benzene concentrations, which have ranged from 2.1 to 48 µg/L. Nitrate and ferrous iron concentrations are below detectable levels. Sulfate concentrations in MW-0056R range from between 130,000 to 290,000 µg/L. Available DO concentration and ORP value data reveal that this monitoring wells is strongly under the influence of sulfate-reducing conditions.

Thus, for this region of the Central Yard, areas impacted by benzene are more reduced than background areas. This region of the Central Yard therefore follows the traditional subsurface redox fingerprint for a region where hydrocarbons are being actively bioremediated.

In summary, benzene concentrations in the Central Yard are generally trending downward. In addition, the Central Yard does appear to follow the traditional fingerprint for MNA, where higher benzene concentrations are associated with lower redox conditions. However, this inverse relationship is less clear in AOC 36, likely due to repeated and recent injections of EISB material specifically designed to transform the subsurface geochemical profile. All subsurface geochemistry suggests that conditions found in the Central Yard are favorable for the biological biodegradation of benzene. In addition, available data suggests that the natural attenuation of benzene has been, and continues to be, active in this region of the Facility.

6.2.2 Main Yard

The Main Yard, like the Central Yard, contains regions of both low and high concentrations of benzene. However, more of the Main Yard is impacted with benzene than is the Central Yard (**Figures 8** through **10**). The northern end of the Main Yard is bounded by the Woodbridge Creek. Multiple ISCO CMs have been completed within the Main Yard, targeting some of the areas of higher benzene impact. ISCO processes involve chemicals being injected or mixed into impacted soil to chemically oxidize target contaminants, such as benzene. The indigenous microbiology is also altered during this process by being subjected to sudden and intense oxidizing conditions (Fedrizzi et al. 2017; Polli et al. 2018; Sutton et al. 2015). As such, for the

purposes of the MNA discussion in this section, Parsons has selected wells located outside of areas strongly influenced by the various ISCO CMs within the Main Yard to represent various unaltered biogeochemical states

Monitoring wells still affected by previous ISCO CMIs are sampled and evaluated as part of their performance monitoring/long-term monitoring program. Following a return to baseline conditions, and data supporting a downward or stable trend, the monitoring wells will transition into the MNA program. This is discussed further in Section 10.

Overall, benzene concentrations in the Main Yard are typically trending downward in most areas. The footprint of areas impacted by benzene concentrations above 1,000 µg/L has decreased substantially between 2008 and 2021/2022 as shown on **Figures 8** and **10**. This is discussed in more detail in Section 8. Areas with lower concentrations of benzene have also reported reductions in concentration. For example, benzene concentrations historically reported for MW-0039 were detectable but below 1 µg/L. Since 2016, benzene concentrations at this location have been reported below detection limits. Similarly, benzene concentrations in MW-179 have historically been reported ranging from 4 to 14 µg/L (2012 to 2014), but concentrations have been below detectable levels since 2016.

As in the Central Yard, background wells in the Main Yard are dominated by nitrate-reducing processes, as represented by MW-154 (AOC 24), MW-314 (AOC 33), and MW-373 (Former PAOC 84). Benzene concentrations are below detectable levels in these three monitoring wells. Nitrate remains depleted in all three of these background monitoring wells. Ferrous iron concentrations range from 786 to 13,600 µg/L and sulfate concentrations range from approximately 3,000 to 50,000 µg/L. These data suggest that background conditions in the Main Yard remain dominated by nitrate-reducing to iron-reducing redox conditions.

Monitoring wells located in areas of low benzene concentrations are more reduced than those located outside impacted areas. Represented by MW-118, benzene concentrations have ranged from below detectable levels to 2 µg/L. Detected ferrous iron concentrations are highly variable, ranging from 3,230 to 8,100 µg/L. Sulfate concentrations ranged from 710 to 18,000 µg/L. An examination of available DO and ORP data supports that the overall trend for MW-118 is dominated by iron-reducing conditions, which is more reduced than the above-described background wells.

Monitoring wells located in areas of slightly higher benzene concentrations are more reduced than those with lower impacts. Represented by MW-374, benzene concentrations have ranged from below detectable levels to 22 µg/L. Detected ferrous iron concentrations are highly variable, ranging from below detectable levels to 1,200 µg/L. Sulfate concentrations ranged from 23,000 to 310,000 (estimated) µg/L. An examination of available DO and ORP data supports that the overall trend for MW-374 is dominated by sulfate-reducing conditions, which is more reduced than the above-described background wells or monitoring wells containing lower benzene concentrations.

The geochemistry of areas impacted by high concentrations of benzene, but still outside regions historically targeted for ISCO treatments, are represented by MW-125 and MW-273R. Benzene concentrations for these two monitoring wells range from below detectable concentrations to 570 µg/L. Detected ferrous iron concentrations range from below 10,000

to 29,000 µg/L. Sulfate concentrations ranged from 1,500 to 70,000 to 310,000 µg/L. An examination of available DO and ORP data supports that the overall trend for MW-374 is dominated by sulfate-reducing conditions.

In conclusion, benzene concentrations in the Main Yard are typically trending downward in most areas. The footprint of areas impacted by high benzene concentrations (above 1,000 µg/L) has decreased substantially over time. Subsurface conditions in the Main Yard, outside of known ISCO-impacted areas, appear to follow the traditional MNA fingerprint of there being an inverse relationship between benzene concentrations and subsurface redox conditions. This suggests that natural attenuation has been, and continues to be, active in this region of the Facility. Furthermore, all subsurface geochemistry suggests that conditions found in the Main Yard are favorable for the biological biodegradation of benzene.

6.2.3 East Yard

As in the Main Yard, the East Yard has experienced repeated ISCO events to break down targeted areas of high benzene concentrations. The East Yard also may experience possible tidal influences, since the eastern boundary is the Arthur Kill. Although limited tidal influences on groundwater in the East Yard are suspected, these possible tidal influences have not been quantified. Tidal studies performed in SWMU 8 and in the area surrounding the former East Yard Basin demonstrated that tidal fluctuations in the Arthur Kill had little to no influence on groundwater elevations in the East Yard.

Although the extent of these possible, limited tidal influences on factors other than groundwater elevations is unresolved at this time, these tidal influences can disrupt the typical fingerprint of hydrocarbon MNA because fresh nutrients are regularly washing into an effected area (Chevron 2008a). In addition, non-contaminant organic matter can wash into the system, providing material for the indigenous microbial population to degrade in preference to hydrocarbon contaminants. This will cause depletion of the TEA markers typically used for indirect MNA monitoring (Chevron 2008b).

In general, benzene concentrations are trending downward in many, if not most, monitoring wells in the East Yard (**Figures 8** through **10**). This is discussed in more detail in Section 8. Benzene concentrations in some monitoring wells, such as MW-271 and MW-288, appear to fluctuate over time. Benzene concentrations in MW-271 have continuously exceeded 100 µg/L since 2020, reaching a recent high concentration of 2,500 µg/L in April 2021, but have trended down since then. Benzene concentrations in MW-288 ranged between 160 and 1,600 µg/L in 2021 alone. These two monitoring wells, which reported high benzene concentrations during their latest sampling event, are clustered near one another (**Figures 8** through **10**). It is suspected that fluctuating benzene concentrations in these two monitoring wells may be a result of rebound after the CMs in the area ceased.

Background conditions, where benzene has historically been and continues to remain below detectable concentrations, are located in less tidal areas, as represented by MW-141 (SWMU 42 AOC 38) and MW-145 (AOC 27). Both monitoring wells report concentrations of nitrate that are below detectable levels. Ferrous iron concentrations were also low, ranging from being below detectable levels to 370 µg/L. Sulfate levels were generally elevated in these two monitoring wells for this period, ranging from 37,200 to 93,900 µg/L. This suggests that both

monitoring wells are dominated by nitrate-reducing to very mild iron-reducing conditions, which is supported by field parameter data including DO concentrations and ORP values.

Background monitoring wells that are under a possibly increased level of tidal influence are represented by MW-144 and MW-253 in AOC 14. Nitrate concentrations in both monitoring wells are reported to be below detectable levels. Ferrous iron concentrations remain higher than found in the less tidal background wells, ranging from 5,600 to 1,600,000 µg/L. Similarly, sulfate concentrations remain higher in more tidal background wells in comparison to non-tidal background wells. Sulfate concentrations in MW-144 and MW-253 ranged from 4,100 to 1,600,000µg/L. Thus, the general trend is for background wells to be under the influence of nitrate reducing conditions. However, ferrous iron and sulfate concentrations are higher in those background wells that are more likely under a tidal influence compared to those that are not, suggesting that there may also be an outside influence of iron-reducing conditions in these monitoring wells. The Arthur Kill waterway could be flushing nutrients, such as ferrous iron and sulfate, from other locations to this Facility. This would explain the relatively mild anaerobic conditions, specifically nitrate-reducing conditions, reported by collected field parameter data such as DO concentrations and ORP values. Given that these monitoring wells have historically had, and continue to have, benzene concentrations that are below detectable levels, a dominance of nitrate-reducing conditions would follow the standard fingerprint for MNA.

Monitoring wells in low benzene concentration areas possibly impacted by ISCO are represented by MW-236 (SWMU 10) and MW-245 (SWMU 42). Both monitoring wells report below detectable concentrations of nitrate. Ferrous iron concentrations ranged from 2,300 to 10,000 µg/L. Sulfate concentrations ranged from 600,000 and 1,220,000 µg/L in MW-236 and between 2,000 to 20,000 µg/L in MW-245. Thus, these wells appear to be primarily dominated by iron-reducing conditions. This is supported by available DO concentration and ORP value data.

Benzene concentrations are also low in MW-270 (AOC 31). ISCO was performed in areas surrounding this monitoring well in 2015 and again in mid-2017 into 2018. Nitrate concentrations in MW-270 remain depleted. Ferrous iron concentrations range from 76,700 to 80,700 µg/L, and sulfate concentrations range widely, from 12,300 to 647,000 µg/L. An examination of historical and current field parameters such as DO concentrations and ORP values support that this region of the East Yard is dominated by strongly anaerobic sulfate-reducing conditions. This is unexpected, given the relatively low benzene concentrations. Thus, this monitoring well may represent legacy subsurface geochemistry from repeated ISCO events.

There are two main areas in the East Yard in which monitoring wells have elevated benzene concentrations (100 to 999 µg/L) – one near the western side (represented by MW-296, MW-408R, and MW-447R) and one area near the eastern side (represented by MW-400 and MW-452) (**Figures 8** through **10**). Starting with the cluster of monitoring wells on the western side of the East Yard, benzene concentrations range from 18 to 260 µg/L. Nitrate concentrations are below detectable levels, and ferrous iron concentrations are not available. Sulfate concentrations are very high, ranging from 2,500 to 36,000 µg/L in MW-296 and from 260,000 to 20,000,000 µg/L in the remaining two monitoring wells. Available DO

concentrations and ORP values support that these monitoring wells are dominated by iron-reducing to sulfate-reducing subsurface conditions.

Two monitoring wells located in the eastern half of the East Yard contain elevated benzene concentrations (defined above) that are representative of area conditions. MW-400 and MW-452 report benzene concentrations that range from 5 to 360 µg/L. Nitrate is depleted in both monitoring wells, and ferrous iron concentrations range from below detectable levels to 31,000 µg/L. As with monitoring wells in the western area of the East Yard, sulfate concentrations are relatively high, ranging from 26,00 to 4,900,000 µg/L. Available DO concentration data and ORP values support that MW-400 (located more inland) is dominated by sulfate-reducing conditions. This is anticipated, given the elevated concentration of benzene present. In contrast, groundwater in MW-452 is dominated by mildly aerobic to microaerophilic conditions. More strongly anaerobic conditions would be expected given the benzene concentrations detected in this monitoring well. However, the location of this monitoring well, which is much closer to the Arthur Kill waterbody, likely facilitates artificial aeration of the subsurface and thus inflated DO concentrations and ORP values.

The benzene concentrations detected in monitoring wells MW-271 and MW-288 have been discussed above. Nitrate is depleted in both monitoring wells, and ferrous iron concentrations have ranged from between 711 and 12,600 µg/L in MW-271 in 2020. In MW-288, ferrous iron concentrations ranged between 7,600 and 8,300 µg/L in 2021. Sulfate concentrations have ranged from 930,000 to 8,850,000 µg/L in MW-271 and from 2,900 to 13,000 µg/L in MW-288. Available DO concentration and ORP values report that MW-271 is dominated by strong sulfate-reducing conditions, which follow the trend expected for an area impacted with higher benzene concentrations (**Appendix B**). There is no available, recent field parameter data for MW-288, however, it is anticipated that similar redox conditions dominate this monitoring well.

These factors indicate the classic fingerprint of MNA is not as clear in the East Yard as it is in the Central and Main Yards. Instead, as demonstrated by the background monitoring well data, there may be an influence of tidal forces on the geochemistry detected within the East Yard. If true, these repeated pulses of fresh nutrients into the East Yard could blur the traditional pattern of TEA depletion when microbial processes dominate natural attenuation. Historical ISCO events may also have impacted areas farther from the injection areas than initially thought, affecting the groundwater geochemistry in some of the discussed wells. Furthermore, many of the tank basins within the East Yard are unlined and regularly flood. The impact that this has on MNA parameters is unclear. This is not to say that biological attenuation is not occurring in the East Yard. Instead, the classic fingerprint of hydrocarbon natural attenuation is likely masked by the impacts of other site conditions and activities. Furthermore, all subsurface geochemistry suggests that conditions found in the East Yard are favorable for the biological biodegradation of benzene.

6.3 Summary

Benzene biodegradation can occur across a wide range of environmental conditions. An assessment of groundwater geochemistry at this Facility confirms that, although conditions

are highly variable across the three yards, they are consistently within a range that is conducive for the MNA of benzene.

An evaluation of MNA-related geochemistry parameters versus benzene concentrations in groundwater was conducted for all three yards of the Facility. A typical fingerprint for hydrocarbon bioremediation is one where areas of higher COC concentration are coupled to more highly reduced subsurface conditions. Furthermore, areas of lower COC concentrations are typically associated with less reduced subsurface conditions. Several MNA-related geochemical parameters have been monitored at this Facility, including (but not limited to) pH, ORP values, and groundwater concentrations of DO, nitrate, ferrous iron, and sulfate. The anticipated, classic fingerprint for benzene MNA was observed in various areas of each yard within the Facility, supporting the case that benzene-related MNA has been, and continues to be, active at this Facility.

However, given the complex history of CMs at the Facility, the traditional MNA-parameter fingerprint was not always easy to discern. This was particularly true in areas where ISCO and EISB have occurred, causing significant alterations to subsurface geochemistry that can artificially mask a traditional MNA fingerprint. However, even in these situations, environmental conditions remain within a favorable range for benzene-MNA to occur, and evidence for MNA does exist. Additional lines of direct evidence for the occurrence of benzene MNA are provided in the next section.

7.0 MOLECULAR MICROBIOLOGICAL AND STABLE-ISOTOPE STUDIES

As previously stated, it takes more than one type of data to demonstrate the occurrence of a natural attenuation process (ASTM, 2022; USEPA 1999). Section 6 provides an evaluation of MNA-related geochemical data such as concentrations of nitrate, ferrous iron, and sulfate, which can indirectly provide information about associated subsurface microbiology. However, modern advances in molecular biology and isotopic chemistry have allowed for quantifiable and direct biological assessments. Some of these direct assessments have been performed at this Facility. The various molecular and stable isotope analyses performed at this Facility to assist with evaluating the Facility microbiology responsible for the bioattenuation of benzene are discussed in this section.

7.1 Introduction

Two major classifications of modern, direct-monitoring technologies – molecular and stable-isotope technologies – have been used at this Facility to glean precise information about indigenous microbial populations of benzene-biodegraders.

7.1.1 Molecular Microbiological Tools: An Overview

Two types of analyses within the molecular biology class of technologies were performed at this Facility – a full community metagenomic analysis and various analyses that are an adaptation of a technique called a quantitative polymerase chain reaction (qPCR) (ASTM, 2022).

7.1.1.1 Metagenomic Analysis

A metagenomic analysis is a molecular method of evaluating an entire microbial community within a sample. Whereas qPCR-based technologies use a molecular probe to deliberately target a specific DNA segment (called a "gene"), no such *a priori* targeting is performed with a metagenomic analysis. Instead, a metagenomic analysis evaluates a community's full-population members as well as their functions, activities, and capabilities. A metagenomic assessment can provide insights into how diverse a population is, what organisms make up the total population (as well as relative quantities in relation to one another), and what functions are being conducted in relative amounts to other functions. In short, it is a full-community assessment of who makes up the community and what these community members are doing. This information is important when trying to understand the potential for an indigenous population to conduct an activity such as benzene biodegradation.

To perform metagenomic analyses at this Facility, groundwater was collected from targeted wells (described in more detail below) using standard best practices and shipped overnight to SiREM Laboratory (SiREM) in Knoxville, Tennessee. Once received at SiREM, each groundwater sample had its microbial population filtered, concentrated, collected, and subjected to two metagenomic analyses. The first analysis identified the members of the full community, and the second evaluated the full suite of community metabolic functions being performed.

7.1.1.2 Introduction to qPCR Technology

To directly monitor the indigenous microbiology associated with biodegradation reactions at the Facility, groundwater from each target area was subjected to one or more qPCR analyses. A qPCR analysis is a well-established technique in which a special molecular probe is created to amplify a specific genetic sequence. This genetic sequence can be chosen to target a specific group of microorganisms (such as "all sulfate-reducing bacteria") or specific functions (such as the process of cleaving open the benzene aromatic ring under anaerobic conditions). The target of the molecular probe can also be designed to be either highly specific or more broad-reaching, for genes associated with either microbial population identity or metabolic functions. However, a key component of a qPCR analysis is that each individual molecular probe also has a fluorescent moiety. The concentration of this fluorescent marker is quantified at the end of the qPCR process and is then used to back calculate to the number of gene copies in the original sample. The number of gene copies is then related to the number of target organisms in the initial sample. Thus, in this manner, a qPCR analysis can quantify the population size of organisms in a sample that have the identity or function that the particular probe was designed to target.

7.1.1.3 QuantArray (Petro) qPCR Analysis

Groundwater from targeted wells (described in more detail below) was collected using standard best practices and shipped overnight to the laboratories of Microbial Insights, Inc. (Microbial Insights) in Knoxville, Tennessee. Once received at Microbial Insights, each groundwater sample had its microbial population filtered, concentrated, collected, and subjected to a QuantArray (Petro) analysis. Microbial Insights has bundled together a selection of 22 different qPCR reactions that focus on the biodegradation of benzene and other hydrocarbons. This QuantArray (Petro) analysis included an evaluation of both common metabolic processes involved in the attenuation of these compounds as well as those microbes commonly involved in their breakdown.

Facility-specific questions that can be answered by the QuantArray (Petro) technology include:

- Are benzene-degrading bacteria present?
- If benzene-degraders are present, what is the size of the population?
- Are population sizes different between one area of a site and another (such as within and outside of any excavated areas)?
- Regarding monitoring Facility efforts, has the size of a target population changed because of site modification efforts such as a bionutrient augmentation process?
- Are specific benzene-degrading mechanisms (such as aerobic or anaerobic processes) occurring and to what degree?
- Is the biodegradation of other Facility hydrocarbons competing for microbial resources?

7.1.1.4 The ORM-2 qPCR Assessment

In this analysis, the population size of the *Deltaproteobacterium* species ORM-2 (ORM-2) was quantified via a qPCR assessment. This was performed using a gene probe specifically targeting the ORM-2 microbe, which is a bacterium known to biodegrade benzene under sulfate-reducing to methanogenic conditions.

Although there are multiple metabolic pathways for anaerobic benzene bioattenuation to occur, the exact mechanisms (and thus the genes involved) are still not fully known for most of these pathways. However, studies confirm that benzene is biodegraded in substantial amounts in the presence of the ORM-2 bacterium even though the exact metabolic pathway(s) for the anaerobic biodegradation of benzene by the ORM-2 microbe has not been fully elucidated. Additionally, the population size of ORM-2 often increases in the presence of benzene when the correct geochemical conditions exist. This is important because it means that not only can the ORM-2 microbe break-down benzene, but the microbe can use it as a resource for population growth. Population maintenance and growth is a key element for successful MNA as well as successful enhanced bioremediation.

These studies have provided evidence that the presence of the ORM-2 bacterium, as part of an indigenous microbial population, is highly desirable when benzene is the hydrocarbon that must be biodegraded. These studies have also shown that the ORM-2 organism can be a central part of an enhanced bioremediation program when correct site conditions are present.

To perform the qPCR analysis targeting ORM-2, groundwater from targeted wells (described in more detail below) was collected using standard best practices and shipped overnight to SiREM. Once received at the laboratory, the microbial population in each groundwater sample was filtered, concentrated, collected, and subjected to an ORM-2 qPCR analysis.

7.1.2 Stable Isotopic Analysis: An Overview

7.1.2.1 In-Situ Microcosms (Bio-Traps®)

Bio-Traps® are the proprietary in-situ biological sampler made by Microbial Insights. Each is composed of a perforated polyvinyl chloride (PVC) tube, capped off at each end, and filled with BioSep™ beads. BioSep™ beads (also proprietary to Microbial Insights) are made of an activated carbon and Nomex® mixture, which has been sterilized and heated until all residual biomarkers are burned off. Once the beads have been both sterilized and cleaned of residual biomarkers, they are “baited” with an isotopically labeled target compound (such as benzene, which was the compound used for this Facility).

These beads are then packed into the sterile Bio-Trap® PVC housing, and the resulting sampler is placed into the targeted monitoring well, where indigenous groundwater microbes will enter the bead’s pore spaces. The presence of a carbon source (isotopically-labeled benzene), coupled with the high degree of porosity of the beads, will attract indigenous microbes to enter the beads once the samplers are put into groundwater. These resident benzene-degraders will then start metabolizing the labeled benzene that was sorbed to the beads, and the isotopic label will be subsequently transferred from the benzene into the degrader’s biomass.

After a few weeks, the Bio-Trap® is removed from the monitoring well and sent back to the Microbial Insights laboratory. After opening the Bio-Trap® PVC housing, half of the beads are sent for geochemical assessments including:

- How much isotopically labeled carbon dioxide was captured within the beads (the carbon dioxide having been generated from the labeled benzene being fully mineralized by groundwater microbes); and

- How much of the labeled benzene remains? From this, it can be calculated how much benzene was consumed during the deployment timeframe, and an approximate in-situ degradation rate can thus be calculated.

The other half of the beads taken from the sampler are subjected to biological testing. These beads are first washed, removing all bacteria that had inhabited the beads during deployment (benzene degraders and other non-degraders that were also indigenous to the groundwater). The number of cells containing the isotopic tag are then counted. Because the only way this tag could become present in the microbial biomass is by the bacteria consuming the tagged benzene, the size of the indigenous benzene-degrading population can be calculated. Finally, the laboratory also investigates the total microbial population found to have inhabited the BioSep™ beads, including those bacteria that did not metabolize the target, isotopically labelled compound. Specifically, certain molecules within the cell membranes of these microbes are analyzed. From this assessment, the following information can be learned.

- A full profile of the major groups that make up the indigenous microbial community (fermenters, anaerobes, proteobacteria, and others) is determined. The diversity of the overall indigenous community is related to the health of this community.
- How metabolically stressed is the benzene-degrading microbial community?
- Is this microbial stress because of the presence of something toxic, or is the stress likely due to lack of a required nutrient?

These Bio-Traps® analyses are also often referred to using the more generic term of stable-isotope probe (SIP) assessments.

7.2 Analyses Performed

Multiple molecular microbiological and stable isotope technologies were implemented at the Perth Amboy Facility to assist with the delineation of the subsurface biogeochemical conditions. These assessments have been performed within AOC 36 (Central Yard) and AOC 44 (Main Yard) (**Figure 3**) in accordance with ASTM international standards (ASTM, 2022) and are discussed below.

7.2.1 AOC 44

Multiple molecular microbiological and stable isotope technologies were implemented within AOC 44, which is in the Main Yard (**Figure 3**). These assessments are summarized here, but a much more detailed description of the analyses and the results can be found in the report on the EISB IWP for AOC 44 (Chevron 2019d).

Five monitoring wells were subjected to an in-depth biogeochemical assessment to evaluate current conditions. The overall goal was to determine if benzene biodegradation is likely occurring. Assessing the chances of successful enhanced benzene biodegradation was also a goal. The following analyses were performed for each of the five monitoring wells targeted:

- Metagenomic analyses of full community members, targeting both the community composition and function
- qPCR to target and quantify ORM-2

- SIP analysis
- A broad range of groundwater geochemical analyses to evaluate the concentration of VOCs, and semi-volatile organic compounds (SVOCs). Details can be found in **Appendix A**
- A broad range of groundwater MNA parameters including those discussed earlier and provided in **Appendix B**

Overall, site conditions within AOC 44 were found to be anaerobic and to generally fall into the iron-reducing to possibly sulfate-reducing conditions in some areas. More reduced groundwater conditions are related to higher COC concentrations. This is a common fingerprint at locations where hydrocarbon MNA is occurring.

A diverse microbial population was present in each of the tested monitoring wells. This population ranged from aerobes to anaerobes, likely due to extensive microenvironments within the subsurface. The microbial diversity reported for each of the five monitoring wells was confirmed by the metagenomic community member assessment, the metagenomic community function assessment, and the SIP survey. This diversity is important because it allows for better overall community resilience and health. It is also important regarding the ability for the indigenous microbial population to successfully conduct MNA on site COCs. Taken together, these data revealed that a wide range of microbes made up the total population in each sample, and that a wide range of microbial functions were occurring in each sample. It is important to note that hydrocarbon degraders were found (and were active) in all samples. In addition, *Proteobacteria* bacterial populations were found in all five samples. This class of bacteria is recognized for their ability to biodegrade a wide range of COCs, including but not limited to hydrocarbons, specifically benzene.

The presence of the *Deltaproteobacterium* ORM-2 microbe found in each sample was extremely significant because this microbe is known to specifically biodegrade benzene under the same environmental conditions found in AOC 44. The fact that the ORM-2 microbe was present at a moderate population size at the site strongly supported historical benzene loss trends in the area, likely due to MNA. The presence of the ORM-2 population was also a positive factor because this is the organism that would be used in any enhanced bioattenuation activity at the site. The fact that it was present at a significant population size suggests that any added ORM-2 would successfully thrive and actively biodegrade benzene at the location.

The belief that enhanced benzene biodegradation would be successful within AOC 44 was further strengthened by the fact that the Bio-Trap® samplers confirmed that benzene biodegradation was currently occurring within each of the tested monitoring wells. Benzene biodegradation was confirmed by the incorporation of the ^{13}C-isotopic tag into bacterial biomass in all samples as well as carbon dioxide in most samples. The only way that this isotopic tag could have become incorporated in this manner is from the microbial breakdown of the isotopically labelled benzene into chemical units that could subsequently become incorporated into either biomass or carbon dioxide. The presence of an indigenous, benzene-degrading microbial community in all tested wells was significant because it strengthened the proposition that MNA of this conservative indicator COC is occurring. It also suggested that any enhanced bioremediation activities targeting benzene would be successful.

In summary, groundwater COC geochemistry and MNA parameters indirectly suggested that MNA had been occurring within AOC 44. This was supported by microbial population membership and function data as well as direct evidence of in-situ benzene biodegradation under site conditions. This data also collectively supported the idea that enhanced biodegradation of benzene, a conservative indicator of overall hydrocarbon biodegradation, would also show favorable results.

The subsequent results of the 2020 EISB effort in AOC 44, which targeted benzene, can be found in **Appendix A**. Looking at the three monitoring wells specifically within the EISB treatment zone, benzene concentrations in MW-233 have reduced from 330 to 190 µg/L (a 42.4% reduction). Benzene concentrations in MW-350 have reduced from 190 to 3.3 µg/L (a 98.2% reduction). Benzene concentrations in MP-06R have reduced from 4400 to 0.3 (U) µg/L (a 99.9% reduction).

7.2.2 AOC 36

A QuantArray (Petro) analysis was performed in 2022 within AOC 36, which is in the Central Yard (**Figure 3**). Seven of the eight evaluated locations reported detectable concentrations of genes associated with specific populations and functions associated with benzene biodegradation. Details of the QuantArray (Petro) analysis can be found in **Appendix D**. Most monitoring wells reported multiple possible benzene-biodegrading microbial populations. But as importantly, seven of the eight locations reported detectable concentrations of metabolic functions possibly associated with benzene bioattenuation.

The reason that some genes are said to detect metabolic functions that are "possibly" associated with benzene biodegradation, as opposed to being certain that benzene is being acted upon, is that it is normal for microbial genes to be capable of functioning on multiple substrates. For example, the phenol hydroxylase gene adds a functional group to a benzene ring, helping to cleave it open, which subsequently makes the remaining compound much more sensitive to further breakdown. But this gene also functions similarly on toluene and the various xylene isomers. As such, the detection of the phenol hydroxylase gene in an area where benzene is present is suggestive that benzene is a target of its activity, but it is not certain.

Despite this, there is strong evidence to suggest that the indigenous microbes in AOC 36 are actively biodegrading benzene. This evidence includes the number of both known benzene-biodegrading microbial populations and benzene-related functional genes detected in almost all AOC 36 samples. The detected functional genes are associated with benzene-degrading metabolisms that would be expected to occur under the geochemical conditions found in the AOC 36 subsurface.

In summary, benzene biodegradation by indigenous microbes has been shown to be occurring. This is supported by benzene concentration trends as well as molecular analyses that have directly detected and quantified both benzene-degrading microbes and their functions. However, the geochemistry of AOC 36 does not cleanly follow the typical pattern associated with locations where benzene MNA is occurring. This is because the EISB injections, which have recently occurred in the area to target non-benzene COCs, have interfered with the generation of any MNA fingerprint. However, the above-described molecular data provides additional lines of evidence that strongly support the proposition that benzene MNA is actively

occurring. This molecular data directly evaluates the indigenous microbial community, and the results clearly reflect that multiple benzene-biodegrading microbial populations are active in AOC 36. These populations are known to survive and thrive in the environment created by the EISB injections. This is supported by the number of different functional genes associated with benzene.

7.3 Summary

Multiple molecular microbiological and stable isotope technologies were implemented at the Perth Amboy facility to assist with the delineation of the biogeochemical conditions of the subsurface. These technologies are a modern, scienced-based, regulator-approved, and direct way to determine if desired microbial community members and functions are present and active in an environment.

These evaluations were performed within AOC 36 and AOC 44, respectively, between 2020 and 2022. The results have provided multiple lines of direct evidence that an indigenous benzene-biodegrading microbial population exists and, most importantly, is active in the subsurface of this Facility. The evidence provided by these molecular and stable-isotope assessments has also shown that benzene biodegradation is occurring by multiple different microbial populations and through multiple metabolic pathways. This diversity is significant because it suggests that current benzene biodegradation will continue into the future, even if subsurface geochemical conditions shift over time through natural processes or due to implemented CMs.

8.0 CURRENT STATE OF BENZENE PLUMES

One of the multiple lines of evidence used to demonstrate the natural attenuation of a compound is to assess plume stabilization and/or loss of contaminant mass over time. This is addressed in this section.

8.1 Benzene Plume Behavior

At this Facility, the goal of the MNA CM is to reduce dissolved phase benzene concentrations in groundwater within the selected treatment areas to below 1 µg/L. A primary line of evidence for assessing the efficiency of natural attenuation is to monitor contaminant mass/concentrations over time and distance to establish plume stability. The most complete historical reference available to facilitate this comparison is data from the time of the 2008 CMS.

8.1.1 Historical Distribution of Benzene in Groundwater

Multiple comingled benzene plumes were identified in each of the three yards in the 2008 CMS (**Figure 8**). The plumes were generally associated with a known or suspected source of benzene, either in soil or from LNAPL. The highest concentrations of benzene were generally found near the soil or LNAPL source, with decreasing concentrations extending downgradient (Chevron 2008a). Historical benzene data is presented in **Appendix A**. The discussions in this report are focused on shallow groundwater since benzene impacts are not present in deep groundwater.

Since 2013, the implementation of CMs in all three Yards has effectively reduced both soil and LNAPL sources in several areas, as discussed in detail below. Post-implementation dissolved benzene concentrations indicate that source removal is complete in some areas, and dissolved benzene concentrations have decreased accordingly. The benzene groundwater plumes over time from 2008, Q2 2017 through Q1 2018, and Q2 2021 through Q1 2022, respectively, are shown in **Figures 8, 9,** and **10**. The contemporary data presented in **Figures 8, 9,** and **10** are the highest concentrations reported during each period. As such, the resulting maps represent the most conservative interpretation of current plume conditions. When the 2017-2018 footprint is compared to current data (Q2 2021 through Q1 2022), it is apparent that the total amount of benzene present at the Facility has been significantly reduced (**Figure 10**).

Footprint Size of Dissolved Benzene Concentrations (square feet)

Footprint Size of Dissolved Benzene Concentrations (square feet) Year	MNA Area (>1 µg/L and <100 µg/L)	Remaining CMI Area (>100 µg/L)	Total Footprint	Number of Monitoring Wells
2008	3,287,218.98	289,744.94	3,576,963.92	220
2017-2018	3,291,472.03	215,042.06	3,506,514.09	292
2021-2022	3,012,207.07	205,335.22	3,217,542.29	277

Since 2008, over 84,400 square feet of the Facility have seen a reduction in benzene concentrations from above the CMI action level (100 µg/L) to below this target concentration. CMs were completed in areas where concentrations were historically above 100 µg/L. Areas with benzene concentrations below 100 µg/L but above the GWQS will continue to be remediated through MNA. The total footprint of dissolved benzene above GWQS of 1 µg/L had slightly increased from 2008 until 2018 but has decreased by 279,250 square feet in 2022. Several plumes that were not identified at the time of the 2008 CMS were identified in 2018 and have reduced in 2022.

It was expected that, once source removal/treatment was completed, the decrease in areas of high concentrations would result in an apparent increase in the footprint of low concentrations (1 to 100 µg/L) of benzene. Over time, however, the footprint of these low concentrations will decrease. This is because there has been a reduction in flux to the lower concentrations of dissolved phase contaminants. Additionally, the biodegradation of contaminants, such as hydrocarbons, occurs primarily in the lower-concentration zones of a plume.

There are multiple reasons for bioattenuation to be more active in zones peripheral to a plume core. First, more microbes are adapted to survive in, and then degrade, lower concentrations of a hydrocarbon than higher concentrations. In addition, areas of lower hydrocarbon concentration are often associated with less-reduced geochemical conditions, as seen at the Facility and discussed above. As such, the actual rate of biodegradation is commonly most rapid in areas of lower dissolved-phase hydrocarbon concentrations.

8.1.2 Historical Decreases in Contaminant Concentrations Over Time

Dissolved benzene concentrations in Facility groundwater exceeding 100 µg/L generally extend from a defined source zone, typically petroleum hydrocarbon impacted soil or LNAPL. Once the source zone has been removed or treated through active remediation, concentrations of benzene in groundwater can follow the MNA patterns discussed above. A detailed assessment of all additional Facility COCs is beyond the scope of this report. Instead, this report focuses on benzene, as directed in the 2008 CMS Report (Chevron 2008a).

8.1.2.1 Central Yard

The Central Yard of the Facility has shown a reduction of the footprint of benzene concentrations above 100 µg/L since 2008 (**Figures 8** through **10** and **Appendix A**). Recently reinstalled monitoring well MW-102R is the only well with current benzene concentrations above 100 ug/L. Several source removal events have contributed to the reduction in total contaminant mass in the Central Yard. Details of each of these remedial actions have been included in previous submittals.

Figures 8 through **10** illustrate that the footprint of concentrations below 100 µg/L and 10 ug/L has been substantially reduced in the Central Yard benzene plumes. Small areas remain where MNA will continue to reduce benzene concentrations. Benzene is currently above the GWQS of 1 ug/L in the AOC 25, AOC 36, and SWMU 11B areas in the Central Yard.

In summary, the footprint of impacted groundwater is significantly reduced in the Central Yard (**Figure 11**). As such, the benzene plume in the Central Yard of this Facility is not only stable but shrinking in both benzene mass and footprint size.

For the Central Yard, it should be noted that:

- In the northwestern plume, an excavation to remove LNAPL and hydrocarbon impacted soil from AOC 25 occurred in September 2016. Concentrations prior to excavation were consistently above CMI action limits. Since the excavation CM, benzene concentrations have consistently been less than 10 µg/L.
- Multiple CMs have been employed near AOC 22, AOC 36, and SWMU 34 in the southern plume. The excavation of benzene-impacted soil was completed in 2013 in AOC 22. EISB was conducted in 2014 in AOC 36, and another EISB event (targeting non-benzene compounds) occurred as recently as 2018 in the MW-216/MW-220 area. The footprint of benzene concentrations less than 100 ug/L in the area has reduced, and this is discussed in detail below. Monitoring well MW-102R was recently reinstalled in August 2019. As discussed earlier, benzene concentrations in this well are currently above 100 ug/L.

Details of each of these remedial actions were submitted under separate covers. Based on the latest available data, only monitoring well MW-102R in AOC 22 has benzene concentrations above the CMI action limit of 100 µg/L (**Appendix A, Figure 10**). Benzene is above the GWQS of 1 ug/L in the AOC 25 and AOC 22/36 areas.

8.1.2.2 Main Yard

In 2008, the Main Yard was characterized by several distinct areas where benzene concentrations were elevated (**Figure 8**). The primary plume in this yard extends from SWMU 5/21/43 in the northwest to AOC 15/8 in the southeast. This primary plume includes benzene comingled with other COCs. Other benzene plumes within the Main Yard include those near AOCs 5 and 44 (extending to the northwestern corner of the Facility), AOC 33 near the eastern Facility boundary, and AOC 50 at the Truck Loading Rack east of the Main Yard.

A variety of CMI actions have been completed in the Main Yard. Some benzene impacted soil has been placed in the CAMU. This was because either benzene-impacted soil was collocated with lead or benzo(a)pyrene impacted soil, or this CM was in lieu of ISCO injections when the benzene source zone was identified as a limited volume of soil, indicating excavation was more efficient than ISCO injections.

The following CMI actions have been completed in the Main Yard:

- In the northwest corner of the Facility, near AOC 5 and SWMUs 27/29/30/38/39, soil was excavated for ISS/ESS in 2015 and 2016. An area of elevated benzene concentrations (above 100 µg/L) in groundwater near MW-404R and MW406 was not identified in 2008 but was detected in 2017/2018. Concentrations of benzene had been reduced to below 100 µg/L in 2021/2022.
- In AOC 9A, an excavation to address benzene in soil was completed in 2017. In SWMU 20, located adjacent to AOC 9A, soil was excavated for ISS/ESS in 2016. In 2017/2018, the upgradient extent of this plume was defined as extending farther to the south than in 2008, based on information generated from the installation of

MW376 and MW379. In 2021/2022, concentrations of benzene in MW-376 had reduced to below 100 µg/L, and there was a reduction in the upgradient extent of the plume. Concentrations of benzene in the downgradient extent of the plume had decreased from above 100 µg/L in MW266 in 2008 to less than 10 µg/L in 2017-2022.

- In SWMU 43, located to the north of AOC 9A and SWMU 20, ISS, ISCO, and bioremediation CMs were completed in 2019. An area of elevated benzene concentrations (above 100 µg/L) in groundwater was detected near MW-0062 and MW-207 in 2008 and was noted to have extended to MW-0063 and MW-0029 in 2017/2018. Additional monitoring wells were installed throughout SWMU 43 after the CMs were complete. Concentrations of benzene remained above 100 µg/L in 2021/2022 and are being monitored as part of the SWMU 43 post-implementation groundwater monitoring.
- In SWMU 19, an excavation was completed in 2016 to address lead and benzo(a)pyrene. In 2008, benzene concentrations in SWMU 19 groundwater were detected above the GWQS of 1 µg/L. However, concentrations in this area have decreased since then, and an NFA justification for SWMU 19 benzene in groundwater was approved by NJDEP on December 16, 2016. Additional LNAPL and groundwater monitoring is currently being conducted within PAOC 6, located adjacent to SWMU 19.
- In AOCs 23/41 and SWMUs 17/18, soil was excavated for the purpose of conducting ISS/ESS as well as benzene impacts in soil in 2018. Additional monitoring wells were installed throughout the area after the CMs were implemented. Concentrations of benzene remained above 100 µg/L in 2021/2022 and are being monitored as part of the SWMU 18/AOC 23-41 post-implementation groundwater monitoring.
- In AOC 44, ISCO injections were completed in 2014. After implementation, benzene concentrations continued to be above the CMI action level of 100 µg/L. Excavation and EISB injections were completed in 2019 and 2020, respectively. In 2021/2022, concentrations of benzene were detected below 100 µg/L in multiple monitoring wells within AOC 44. The upgradient and downgradient edges of this plume have reduced since 2017/2018, as shown on **Figure 11**. Concentrations of benzene remained above 100 µg/L in 2021/2022 and are being monitored as part of the SWMU 43 post-implementation groundwater monitoring.
- In SWMUs 6/7/16/40, excavation was completed in 2016 to address benzo(a)pyrene and lead in soil. In 2020, excavation and ISCO soil mixing were implemented to address benzene-impacted soil and groundwater. Benzene concentrations in groundwater were detected above 1,000 µg/L in MW-125 and MW-243 in 2008. These concentrations reduced to less than 1,000 µg/L in MW-125 and less than 10 µg/L in MW-243R in 2017/2018. Monitoring wells MW-603 and MW-604 were installed after the CMs were implemented, and concentrations of benzene are above 1,000 µg/L. This Main Yard Plume area is currently being monitored as part of the post-implementation groundwater sampling.
- In AOC 8, benzene concentrations in MW-265 remained above 100 µg/L between 2008 and 2017/2018. An air sparging/SVE CM was started in January 2021. Additional AOC 8 monitoring wells were installed during the air sparge/SVE CM. Concentrations of benzene are currently above 1,000 µg/L in MW-265R, MW-589, and

MW-598R and are being monitored as part of the AOC 8 performance groundwater sampling.

- In AOC 50, a remedial excavation to address lead and benzene in soil in the southern portion of AOC 50 was completed in 2017. A similar excavation was completed in the northern portion of AOC 50 in January 2019. A biosparge system was started in December 2020, and groundwater is currently being monitored as part of the system operations. Benzene concentrations remain above 100 µg/L in MW-521 in the southern portion of AOC 50. However, they are below 10 µg/L in MW-579 in the northern biosparge area.

Details of each of these remedial actions were submitted under prior reports. . Currently, only three of these areas have benzene concentrations in groundwater above 1,000 µg/L, and nine areas have benzene concentrations above the CMI action limit of 100 µg/L (**Appendix A**, **Figure 10**). Additionally, the area near SWMU 39, east of SWMU 43, and south of SWMU 19 and AOC 44 have shown reductions of benzene concentrations to below GWQS of 1 µg/L (**Figures 10** and **11**). A comparison of benzene concentrations and locations between 2018 and 2022 demonstrates that the plumes in this Yard are stable or shrinking into themselves. A detailed discussion on benzene plume footprints is below.

Based on the latest available data, benzene has been detected above the CMI action level in the following areas within the Main Yard: AOC 8, AOC 9A, AOC 41, AOC 44, AOC 50 South, SWMU 6, SWMU 16, SWMU 18, SWMU 24, and SWMU 43. Benzene is currently above the GWQS of 1 µg/L in the following areas within the Main Yard: AOC 50 North, SWMU 35, and SWMU 39.

8.1.2.3 East Yard

In 2008, the East Yard was characterized by several plumes extending downgradient from six source areas. The following CMI activities have been conducted since 2008:

- SWMU 8, located in the northeastern corner of the East Yard, received two rounds of ISCO injections in 2013. and ESS for lead was completed in 2016. In 2008, benzene concentrations in MW-132 were greater than 100 µg/L. Concentrations in MW-132R had been reduced to less than 10 µg/L in 2017-2022, and the SWMU 8 benzene plume extent is reduced as compared to 2008.
- Two rounds of ISCO injections were completed in SWMU 10 in 2015, and ISS/ESS for lead was completed in 2016. Concentrations of benzene in MW-131 were greater than 100 µg/L in 2008 but had decreased to below the GWQS of 1 µg/L in MW-131R in 20212022. Currently, the benzene concentration in MW-386R is above 1 µg/L.
- In 2016, an ESS CM was completed in SWMU 42 to address lead impacts in soil. Benzene concentrations in the ESS CM area (MW-227) were greater than 100 µg/L in 2008 and reduced to less than 10 µg/L in 2018 and to nondetect in 2021.
- Soils with elevated concentrations of benzene in AOCs 14 and SWMU 26 were excavated in 2017. Dissolved benzene concentrations in this area have decreased to less than 10 µg/L since 2008.
- AOC 31 was the site of electrical resistance heating system operations until 2014. ISCO injections in this area were completed in October 2018. The footprint of

concentrations exceeding 100 µg/L has been reduced (**Figures 8** through **11**), and CMs are ongoing in this area. Additionally, benzene concentrations in the downgradient portion of the plume have decreased to less than the GWQS of 1 µg/L along the northern property boundary.

- AOC 38 and AOC 39 were not identified as having elevated benzene in groundwater in 2008. However, the benzene in soil was excavated within AOC 38 in 2017, and excavation and soil mixing were completed in AOC 39 in 2018. Benzene concentrations in MW-400 remain above 100 µg/L. Benzene concentrations in MW-401 have reduced to below the GWQS of 1 µg/L.
- AOC 46 was treated via ISCO injection in 2015. Concentrations of benzene in MW-347 remain less than 10 µg/L, and the remaining wells in the area have been non-detect.
- AOC 37, located in the western portion of the East Yard, and AOC 16 EY1, located south of AOC 37, were not identified as having elevated groundwater benzene concentrations in 2008. However, excavation of benzene impacted soil in AOC 37 was completed in 2016. Soil mixing was completed in AOC 16 EY1 in 2019. Benzene concentrations in groundwater above 100 µg/L were identified in MW-296 in 2017/2018, and in MW-408R and MW-447R in 2021/2022.
- In the area of the State Street parking lot, in SWMUs 11a and 11b, benzene impacted groundwater was discovered after the 2008 CMS. Data from well TP2-018 indicate that benzene concentrations in this area exceeded 1,000 µg/L in 2009. A remedial excavation was completed in SWMU 11a in 2015, and ISCO soil mixing was completed in SWMU 11b in 2017. Data from post-CM implementation monitoring wells MW-438, MW431R and MW-509 indicate that benzene concentrations have been reduced to less than 100 µg/L in the area.

Details of each of these remedial actions have been or will be submitted under separate cover. Currently, one area of the East Yard has groundwater benzene concentrations over 1,000 µg/L, and four areas have benzene concentrations above the CMI action limit of 100 µg/L (**Appendix A**, **Figure 10**). Benzene concentrations in the AOC 46, AOC 38/39, and AOC 31 areas of the East Yard have reduced to below the GWQS of 1 µg/L since 2017/2018 (**Figure 11**). A comparison of benzene concentrations and locations between 2018 and 2022 demonstrates that the plumes in this Yard are stable or shrinking into themselves (**Figures 8** through **10**). Benzene plume footprints are discussed in detail below.

Based on the latest available data, benzene has been detected above the CMI action level in the following areas within the East Yard: AOC 16 EY1, AOC 31, AOC 38/39, and SWMU 8. These areas are being monitored as part of their area specific long term monitoring program. Benzene is above the GWQS of 1 µg/L in the following areas within the East Yard: AOC 14/26, AOC 46, and SWMU 10.

8.1.3 Summary

Since 2013, the implementation of multiple types of CMs in all three Yards at this Facility has effectively reduced both soil and LNAPL sources in several areas. CMs were chosen based on best practices for the target COC(s) and locations at the Facility. Post-implementation dissolved

benzene concentrations indicate that source removal is complete in some areas, and dissolved benzene concentrations have decreased accordingly.

Regarding the Facility as a whole, the distribution of benzene has reduced over time. This is supported by the decrease in Facility footprint for benzene concentrations above 100 µg/L, which would be under the influence of CMs. This is also supported by the decrease in the Facility footprint for benzene concentrations between 1 to 100 µg/L, which would be driven by MNA. A more detailed spatial analysis of Facility benzene plumes, over time, is provided in Section 8.2 below.

8.2 Benzene Trends in Groundwater: Spatial Analysis

As discussed above, the overall footprint of the Facility impacted by benzene at a concentration above 1 µg/L has decreased steadily over time. The total footprint reported in 2008 was 3,576,964 square feet. By the 2017/2018 monitoring period, the benzene footprint had decreased to 3,506,514 square feet. This footprint had decreased further by the 2021/2022 monitoring period to 3,217,542 square feet. This is a 10% reduction in total footprint between 2008 and 2021/2022. The remaining CMI footprint between 2008 and 2021/2022 has reduced from 289,745 to 205,335 square feet. This is more than a 29% reduction in the CMI area footprint because of various CM activities. The footprint of the total area of the facility subject to MNA has also reduced from 3,287,218 to 3,012,207 square feet during this same period. This is a footprint reduction of more than 8% due to biological attenuation of Facility benzene.

A detailed look at the yard-by-yard spatial distribution of benzene is provided below.

8.2.1 Central Yard

Overall, the spatial trend for the footprint of benzene in the Central Yard follows the trend observed for the entire Facility in that the size of the footprint has decreased substantially over time.

Footprint Size of Dissolved Benzene Concentrations – Central Yard (square feet)

Year	MNA Area (>1 µg/L and <100 µg/L)	Remaining CMI Area (>100 µg/L)	Total Footprint	Number of Monitoring Wells
2008	373,392.67	15,890.69	389,283.36	31
2017-2018	402,673.38	0	402,673.38	58
2021-2022	171,954.10	4,678.74	176,632.84	55

The total footprint for the benzene-impacted area within the Central Yard has decreased from 389,283 to 176,632 square feet between 2008 and 2021/2022. This is a 55% decrease. An evaluation of the footprint of the remaining CMI area appears to show that the footprint was totally removed between 2008 and 2017/2018, with benzene concentrations over 100 µg/L reappearing in 2021/2022. This is not the case. Instead, many additional monitoring wells

were installed in the Central Yard between 2008 and 2017/2018, particularly in the AOC 36 area (**Figures 9** and **10**). These additional monitoring points were installed specifically to target groundwater areas of interest. As a result, benzene was more accurately delineated and reported. As such, assessing the footprint of this portion of the plume in isolation gives the false impression that benzene (at a concentration above 100 µg/L) has returned to the Central Yard. In reality, this is simply an artifact of additional monitoring locations and better plume delineation resulting in a more refined model of benzene location.

Regarding the area of the Central Yard being remediated by natural attenuation, this footprint has decreased from 373,392 to 171,954 square feet (a 54% decrease) between 2008 and 2021/2022. This portion of the benzene footprint is under the influence of MNA as its CM. **Figures 8** through **10** clearly show that the two main benzene plumes in the Central Yard are retracting in towards their respective cores, as would be anticipated when biological benzene biodegradation is occurring. This is because MNA works from the lower-concentration periphery in toward the higher-concentration center of a plume. As such, the spatial trends for benzene in the Central Yard support that MNA is an active and successful contributor toward benzene reduction.

8.2.2 Main Yard

Overall, the spatial trend for the footprint of benzene in the Main Yard follows the trend observed for the whole Facility in that the size has decreased substantially over time.

Footprint Size of Dissolved Benzene Concentrations – Main Yard (square feet)

Year	MNA Area (>1 µg/L and <100 µg/L)	Remaining CMI Area (>100 µg/L)	Total Footprint	Number of Monitoring Wells
2008	2,229,723.82	180,662.35	2,410,386.17	106
2017-2018	1,627,508.72	160,839.75	1,788,348.47	123
2021-2022	2,151,309.27	163,043.21	2,314,352.47	133

Similar to the trends noted above for the Central Yard, the footprints of the MNA area, the remaining CMI area, and the total benzene area in the Main Yard have all decreased between 2008 and 2021/2022 (respectively, 4%, 10%, and 5% reductions in footprints).

Similar to the Central Yard, the Main Yard benzene footprint data over time also creates a false impression that there has been an increase in the footprint of total benzene between 2017/2018 and 2021/2022. However, this appears to be an artifact of the increased number of monitoring wells installed in the Main Yard between 2008 and 2017/2018. This increased monitoring has produced a more refined understanding of where benzene is located. This is likely also why the raw data for the footprint of the Main Yard's CMI area benzene (with a concentration over 100 µg/L) and MNA area benzene (with concentrations between 1 and 100 µg/L) appear to have increased between 2017/2018 and 2021/2022. However, additional

monitoring locations installed between these dates have simply better delineated and modeled the locations and concentrations of benzene in the Main Yard.

As visualized in **Figures 8** through **10**, benzene plumes are clearly shrinking into themselves, as would be expected when MNA is functioning. Furthermore, CMs implemented to address higher concentrations of benzene have left the Main Yard with reduced overall benzene concentrations that would be more amenable to MNA. Thus, as benzene concentrations transition from the CMI area to the lower-concentration MNA area, the overall footprint of the MNA area is expected to increase. The fact that it has actually decreased since 2008 suggests that biological attenuation in the Main Yard is functioning sufficiently to overcome areas of higher benzene concentration transitioning to areas of lower concentration.

8.2.3 East Yard

Overall, the spatial trend for the footprint of benzene in the East Yard follows that for the footprint for the whole Facility in that the size has decrease substantially over time.

Footprint Size of Dissolved Benzene Concentrations – East Yard (square feet)

Year	MNA Area	Remaining CMI Area	Total Footprint	Number of Monitoring Wells
	(>1 µg/L and <100 µg/L)	(>100 µg/L)		
2008	684,102.49	93,191.90	777,294.39	83
2017-2018	1,261,289.93	54,202.31	1,315,492.24	111
2021-2022	688,943.71	37,613.27	726,556.98	89

Similar to the Central Yard and the Main Yard, the overall MNA area footprint in the East Yard appears to have increased substantially between 2008 and 2017/2018. However, this was a time when multiple new monitoring points were established (**Figures 8** through **10**). As discussed above, this reported change in apparent footprint is likely an artifact of better plume delineation and modeling due to an increase in the number of monitoring points. This is also the driver for the apparent (but again, false) "increase" in the overall benzene footprint reported in the East Yard in 2017/2018 in comparison to 2008.

Adjusting for the fact that additional monitoring points have provided for more accurate plume delineation in 2017/2018, there has been a substantial decrease in the MNA area, CMI area, and total yard benzene footprints between 2008 and 2021/2022 (respectively, 45%, 31%, and 45% reductions). This reduction in the footprints of various benzene concentrations is illustrated in **Figures 8** through **10**.

8.2.4 Summary

The addition of more monitoring points in each of the three Yards of the Facility has resulted in more refined plume delineation and modeling. The overall spatial trends for each of the three Facility yards demonstrates that benzene footprints are decreasing over time. Moreover, the fact that footprints are decreasing in areas where MNA is the benzene CM provides a strong

line of evidence that natural attenuation is an effective and significant remedial approach to the degradation of benzene throughout the Facility.

8.3 Benzene Trends in Groundwater Including Graphical Analyses and Statistical Trends

The graphical and statistical trends of benzene concentrations above 1 µg/L in monitoring wells included in the MNA plan is provided below on a yard-by-yard basis. Locations chosen for analysis were in areas currently not in an active remediation monitoring program. In addition, all chosen locations have sufficient data collected over the past 10 years to conduct a proper statistical analysis. Finally, locations were chosen to reflect various benzene concentration ranges. Monitoring wells currently being monitored post active remediation are not included in the trend analysis. A representative number of wells within each yard are discussed below and shown in **Appendix E**.

8.3.1 Central Yard

Benzene concentrations in the Central Yard above the GWQS of 1 µg/L are located within AOC 25 and AOC 22/36. Groundwater quality data were analyzed using the Mann-Kendall statistical method, and the benzene concentrations were graphed over time to determine contamination trends. Monitoring wells MW-0055R and MW-0056R (both within AOC 22) and MW-102R, MW-217, MW-368, and MW-533 (within AOC 22/36) were analyzed, and the results are provided in in **Appendix E**.

Mann-Kendall analyses report decreasing trends for target compound benzene in monitoring wells MW-0055R, MW-0056R, MW-217, and MW-533 and probably decreasing trends in MW-368. Benzene concentrations in MW-102R are currently above 100 µg/L and demonstrates a stable trend with the Mann-Kendall Statistic (S) of -10 and a confidence factor of 78.4% since being reinstalled in 2019. The benzene concentrations plotted over time for MW-102R shows an overall decreasing trend with concentrations ranging between 70 and 240 µg/L. Prior to being abandoned in 2013, monitoring well MW-102 had benzene concentrations over 1,000 µg/L until 2007 and approximately 150 µg/L when abandoned. Soils impacted by benzene was excavated in AOC 22, adjacent to MW-102R.

8.3.2 Main Yard

Benzene concentrations in groundwater in AOC 8, AOC 9A, AOC 41, AOC 44, AOC 50 North, SWMU 6, SWMU 16, SWMU 18, SWMU 24, SWMU 35, and SWMU 43 are being monitored as part of post-remediation sampling. Benzene concentrations in groundwater above the GWQS of 1 µg/L in both AOC 50 South and SWMU 39 as well as outside of the remediation areas were evaluated as part of the MNA program. Groundwater quality data were analyzed using the Mann-Kendall statistical method, and the benzene concentrations were graphed over time to determine the contamination trends. Monitoring wells MW-374 and MW-376 in AOC 9A, MW-378 in AOC 44, MW-404R and MW-406 in AOC 39, and MW-521 in AOC 50 South were analyzed, as shown in **Appendix E**.

Mann-Kendall analyses report decreasing trends for target compound benzene in monitoring wells MW-374, MW-376, MW-378, MW-404R, MW-406, and MW-521. The benzene concentrations plotted over time for these six wells show an overall decreasing trend. Additional rounds of groundwater samples will be collected as part of the MNA sampling program in monitoring wells outside the active remediation areas to obtain enough data points to allow for a more complete trend analysis.

8.3.3 East Yard

Benzene concentrations in groundwater in AOC 14, AOC 16 EY1, AOC 31, SWMU 8, and SWMU 26 are being monitored as part of post-remediation sampling. Benzene concentrations in groundwater above the GWQS of 1 µg/L in AOC 38/39, AOC 46, and SWMU 10, as well as outside of the remediation areas, were evaluated as part of the MNA program. Groundwater benzene concentration data was analyzed using the Mann-Kendall statistical method and then graphed over time to determine the contamination trends. Monitoring wells MW-149 (AOC 14/SWMU 26), MW-292R (AOC 31), MW-347 (AOC 46), MW-386R (SWMU 10), MW-400 (AOC 39), and MW-464 (AOC 16 EY1) were analyzed as shown in **Appendix E**.

Mann-Kendall analyses report decreasing trends for target compound benzene in monitoring wells MW-292R, MW-347, MW-386R, MW-400 and MW-464 and probably decreasing trends in MW-149. Benzene concentrations in MW-149 was detected below the GWQS of 1 µg/L in the last sampling event (March 2022). Benzene concentrations in MW-400, which is located in AOC 39, are currently above 100 ug/L and demonstrate decreasing trends using both the Mann-Kendall statistical method and graphical depictions over time. Excavation of benzene impacted soil and soil mixing to address impacted groundwater was completed in AOC 39 in January 2018.

8.3.4 Summary

Benzene concentrations in groundwater from selected monitoring wells in all three Facility Yards were evaluated by both graphical (concentration versus time) and statistical methods. In general, benzene concentrations are trending downward over time. This is true for all three Facility Yards. This is a result of successful CMs as well as active MNA targeting Facility benzene.

8.4 Benzene Concentrations Over Time: Mass Discharge

Mass discharge involves assessing the movement of contaminant mass of a plume emanating from a site. There is no benzene discharge from the Facility, as visually represented in **Figures 8** through **10**. Groundwater data presented in **Appendix A** also supports this. As such, there is no benzene mass discharge from the Facility to monitor.

8.5 Summary

The implementation of multiple types of CMs in all three Yards at this Facility has effectively reduced both soil and LNAPL sources in several areas. Post-implementation dissolved benzene

concentrations indicate that source removal is complete in some areas, and dissolved benzene concentrations have decreased accordingly, likely through MNA activities.

The addition of more monitoring points in each of the three Yards since 2008 has resulted in more refined plume delineation and modeling. Regarding the Facility as a whole, the distribution of benzene has reduced over time. This trend is also seen in each of the three individual yards. The fact that benzene footprints are decreasing in areas where the benzene CM is MNA provides a strong line of evidence that natural attenuation is effectively degrading benzene throughout the Facility.

Benzene concentrations in groundwater from selected monitoring wells in all three Facility yards were evaluated by both graphical (concentration versus time) and statistical methods. In general, benzene concentrations are trending downward over time. This is true for all three Facility yards. This is a result of successful CMs as well as active MNA targeting Facility benzene.

9.0 SUMMARY OF THE IMPACT OF ISCO AND OTHER SOURCE CONTROL MEASURES ON MNA

There are two major classes of source control CMs used at this Facility: physical removal and destructive methods. Excavation is an example of a physical removal CM, where areas of high benzene concentration have been dug up and relocated. Excavation has occurred in multiple areas of the Facility, and this CM is an effective way to achieve source zone depletion (ITRC 2009). As such, this type of CM facilitates natural attenuation because biological attenuation functions from the periphery of a plume, working inward toward the plume core (Wiedemeier et al. 1999). By removing the higher benzene concentrations found in a plume core (including LNAPL), there is subsequently no longer a source from which the remaining lower concentrations can be replenished. The remaining reduced concentration of target compound is much easier for natural attenuation to address (Wiedemeier et al. 1999). As such, natural attenuation can make accelerate the break- down of remaining product once source material is removed. A detailed discussion on the mechanisms of how source removal facilitates natural attenuation is beyond the scope of this document.

The second major classification of source control used at this Facility includes those CMs that are destructive in nature. Using ISCO as an example, the strategic injection of materials that chemically destroy a target compound in-situ will result in a reduction of COC mass within the targeted area. The targeted area for an ISCO event will commonly include a plume's core. Oftentimes, ISCO events involve the injection of sulfate-based compounds such as sodium persulfate and potassium persulfate to oxidize organic COCs in soil and groundwater. Sodium persulfate readily dissolves to initially oxidize organics over a short time frame. Potassium persulfate, however, dissolves more slowly, and its longer residence time allows for oxidation of organics over longer periods. The intent of oxidant and activator placement is to remediate COCs within the treatment areas as well as in adjacent areas that cannot be accessed for excavation or soil mixing (e.g., beneath above-ground storage tanks, within buffer zones). The persulfate oxidation reaction can also enhance biological degradation of organics by increasing the concentration of sulfate in groundwater, which can then be used by indigenous sulfate-reducing microbes during COC biodegradation processes.

Additionally, as with the above-described excavation process, ISCO and other in-situ destructive CMs typically leave residual target compound with a much lower overall concentration than what existed prior to treatment. This residual material can be more easily addressed by natural attenuation. ISCO and other destructive treatments (including EISB, as was employed in AOC 36 in the Central Yard to target non-benzene COCs) can significantly alter the subsurface geochemistry because of the materials injected during the CM process. However, benzene is known to biodegrade under a wide range of environmental conditions. As such, as long as an indigenous microbial population is able to adjust to the new subsurface environment and re-establish a strong enough population, natural attenuation will be maintained (Wiedemeier et al. 1999).

In summary, source reduction is occurring at this Facility through CMs that function by the physical removal of material or through in-situ material destruction. These source removal CMs have decreased benzene concentrations such that MNA can function more efficiently to further reduce concentrations. Details about specific locations where excavation, ISCO, or other source reducing CMs have been implemented can be found in Section 7.

10.0 SUMMARY OF ANY OTHER MNA RESULTS OBTAINED IN CONJUCTION WITH ISCO ACTIVITIES

When ISCO CMs are proposed for the Facility, a permit-by-rule (PBR) allowing the activity must be issued by the NJDEP. The PBR authorizing the ISCO CM also directs the ISCO-related post-implementation groundwater monitoring that is required to occur. Typically, as part of the PBR, 3- and 6- month remedial effectiveness performance monitoring, sampling occurs following conclusion of the remedy. This monitoring is to confirm reduction of contaminant mass as per the remedial design objective. Following the 2 rounds of performance monitoring, the area transitions to long-term monitoring, which typically includes 8 quarters of data (including the 3- and 6-month data) to evaluate MNA applicability. This will also help determine if groundwater quality has returned to baseline conditions, and some monitoring wells may be transitioned to the MNA program.

As an example of this process, the monitoring of the ISCO CM that occurred in AOC 23, AOC 41, and SWMU 18 (in the Main Yard) will be discussed below (**Figure 3**).

Soil and groundwater in AOC 23, AOC 41, and SWMU 18 treatment areas exceeded the RCRA CMI action levels for benzene in soil (13 mg/kg) and/or groundwater (100 ug/L) (**Appendix A**). As such, it was decided that ISCO was the best treatment option for this area of the Facility. In response to a Facility application, the NJDEP responded in a letter dated September 17, 2020, authorizing the ISCO CM (NJDEP 2020). Section II of this letter described the system operation and monitoring parameters that needed to be maintained during the CM activity. Section III of this letter outlined the post-implementation groundwater monitoring program that would be in place.

Post-implementation monitoring instructions for this area of the Facility included (but were not limited to) the identification of specific groundwater monitoring locations (MW-260RR, MW-261R, MW-267R, MW-551 and MW-550). Additionally, instructions regarding groundwater monitoring were given. For this event, groundwater monitoring was to be performed for VOC+TICs, SVOC+TICs, sulfate, total dissolved solids. In addition, a list of field parameters to be monitored was also provided that included pH, DO, ORP, temperature, turbidity, specific conductivity, and persulfate. Monitoring well sampling was to be performed at 3 months and 6 months after the completion of amendment placement. The results of this post-implementation monitoring can be found in **Appendix A** and **Appendix B**.

Thus, as detailed through the above example, ISCO CM activities are followed by a monitoring program that includes MNA-related parameters such as sulfate and DO concentrations, as well as ORP values. Once required post-remedial conditions have been achieved, the monitoring well will transition into the MNA program.

11.0 CONCLUSIONS

An evaluation of MNA at the Facility indicates that natural attenuation processes are occurring. This is based on the following lines of evidence:

- Benzene has been largely contained on site over decades of time.
- Benzene concentrations and footprint size are decreasing, including in areas not targeted by any active CM reduction methods such as ISCO or excavation.
- MNA geochemical indicators support that Facility conditions are favorable for MNA and demonstrate a clear fingerprint of active MNA.
- Direct molecular analyses in multiple Facility Yards have proven that the indigenous microbial population contains known benzene biodegraders, and these populations have been quantified.
- Direct molecular analyses conducted on groundwater from multiple Facility Yards have quantified multiple metabolic functions associated with benzene bioattenuation.
- Benzene biodegradation is known to occur at the Facility by indigenous subsurface microbes, as demonstrated through SIP analyses.
- Benzene concentrations show decreasing trends demonstrated by graphical analysis and statistical tests.

A comparison of the footprint of various concentrations of benzene since 2008 shows that benzene remains contained at the Facility (**Figures 8** through **10**). As important, benzene concentrations continue to decrease, even in areas where active remediation has not occurred. Furthermore, the actual benzene footprint has decreased since 2008. This is particularly true in areas of mid- to- lower benzene concentrations, which would be the most amenable to biodegradation.

An evaluation of groundwater chemistry shows that conditions present in the subsurface match those that are known to support benzene bioattenuation. Additionally, an assessment of MNA geochemical parameters for each of the three yards shows that a clear fingerprint of biological hydrocarbon degradation is present. The observed, overall trend is that background monitoring wells demonstrated the least reduced environments. The degree of reduction increased as benzene concentrations increased. This was consistently supported by current benzene concentrations as well as multiple MNA geochemical parameters, including concentrations of nitrate, ferrous iron, sulfate, and reported ORP values. This fingerprint would not be seen if only abiotic processes are degrading site contaminants.

A series of analyses have been conducted in multiple yards of the Facility to directly evaluate indigenous microbes potentially involved with the bioattenuation of benzene. The use of stable-isotope analyses has confirmed that benzene bioattenuation by native Facility microbes is actively occurring. In addition, multiple different molecular technologies have identified numerous naturally occurring microbial populations capable of biodegrading benzene as well as their benzene-biodegrading metabolic pathways. Because this stable-isotope and molecular data directly evaluates groundwater microbes, they strongly support the various indirect groundwater geochemical data reflecting that benzene is being naturally degraded at this Facility.

12.0 RECOMMENDATIONS

Two recommended future actions for the Facility were identified during development of this MNA Annual Report.

Because this is the first of two annual reports, it is logical that the first recommendation will be that the list of monitoring wells included in the MNA sampling program be updated in accordance with the sampling plan outline in Section 5.1 above.

Although this report is focused on the MNA of benzene, this hydrocarbon is not the only COC that must be evaluated and tracked at this Facility. Some of these COCs, such as chlorinated ethenes and ethanes, are also amenable to bioattenuation. In fact, many of the same parameters used to indirectly assess the MNA of benzene can also help with an MNA evaluation of these other compounds. In addition, many of these other COCs are co-located in areas of current or historical benzene impacts. As such, a second recommendation is that a single, comprehensive Facility-wide monitoring program be developed covering the COCs relevant to regulatory closure for this Facility. This will provide a more effective and efficient monitoring approach and will help to better identify areas that could qualify for an NFA ruling.

Wells Not Gauged or Not Used for Contouring	
Well ID	**Observations**
A8TP26	Well was dry.
EY4TP48	Well is hydraulically isolated within sheetpile wall.
EY4TP49	Well is hydraulically isolated within sheetpile wall.
MP-05	Did not gauge well. Well was inaccessible. Well was flooded
MP-06R	Did not gauge well. Well was inaccessible. Well was flooded
MP-07	Did not gauge well. Well could not be located.
MP-08	Did not gauge well. Well could not be located.
MW-106R	Did not gauge well. Well could not be located.
MW-12	Did not gauge well. Well could not be located.
MW-147	Did not gauge well. Well was inaccessible.
MW-159	Did not gauge well. Well was inaccessible.
MW-171	Well is hydraulically isolated within sheetpile wall.
MW-173	Did not gauge well. Well could not be located.
MW-174	Did not gauge well. Well could not be located.
MW-175	Well is hydraulically isolated within sheetpile wall.
MW-186	Did not gauge well. Well could not be located.
MW-193	Did not gauge well. Well could not be located.
MW-195	Elevation is anomalous.
MW-197	Elevation is anomalous.
MW-199	Well is hydraulically isolated within sheetpile wall.
MW-201	Well is hydraulically isolated within sheetpile wall.
MW-203	Well is hydraulically isolated within sheetpile wall.
MW-249	Did not gauge well. Well could not be located.
MW-302	Did not gauge well. Well was inaccessible. Car parked on well
MW-364	Did not gauge well. Well was inaccessible.
MW-389	Did not gauge well. Well could not be located.
MW-392	Did not gauge well. Well could not be located.
MW-399R	Well needs a new ID tag.
MW-449	Flooded
MW-456	Did not gauge well. Well could not be located. Well covered by arsenic cap
MW-461	Did not gauge well. Well could not be located.
MW-484	Did not gauge well. Well could not be located.
MW-490	Did not gauge well. Well could not be located.
MW-510	Well needs a new ID tag.
MW-512	Did not gauge well. Well could not be located.
MW-528	Did not gauge well. Well could not be located.
MW-540R	Could not measure depth to water due to thick LNAPL.
MW-576	Missed
MW-585	Missed
P-4	Did not gauge well. Well was inaccessible.
RW-33	Did not gauge well. Well could not be located. Area around well covered with stone.
S40TP1	Did not gauge well. Well could not be located. Area around well covered with stone.
TP2-018R	Elevation is anomalous.
TP2-019	Did not gauge well. Well was inaccessible. Car parked on well

Notes:

1. GWQS - Groundwater Quality Standard
2. Bold, Shaded and Brackets Indicates Exceedance to Criteria
3. NA - No Criterion Available for the Analyte
4. NJDEP Approved Site Cleanup Critera
5. J - Estimated value
6. U - Not detected

MNA Appendix A3 East Yard - VOCs and TICs
Historical Groundwater VOC Concentration Data
