[73] Institute of Medicine, Environmental Decisions in the Face of Uncertainty, Box 2-1 (2013) *available at* https://www.ncbi.nlm.nih.gov/books/NBK200844/box/box_2_1/?report=objectonly (Uncertainty in Environmental Decisions).

[74] 1989 Rule, *supra* note 2, at 51,564.

The vast majority of road construction workers have much lower risks than those calculated in this Petition. Highway construction workers not directly working on the road are located further from the PG and have lower risks.

The risk calculation for the highest RME for a worker placing road base assumes that the PG emits 27 pCi/g exposure for five years. Based on the preliminary data on radiation levels from PG stacks, the average level of radioactivity from the PG material in each sampled stack is less than the nominal 27 pCi/g used in the risk assessment, thus, the risk from these sampled stacks is even further below the EPA risk management safe limit of 3 in 10,000 risk level. The calculated risk is scalable, i.e., if the radioactivity level in a stack is 13.5 pCi/g, the risk is one half of the risk calculated for the nominal radioactivity level of 27 pCi/g (i.e., the 12.5 pCi/g stack corresponds to a 0.275 in 10,000 risk level, significantly lower than the EPA PG risk limit of 3 in 10,000). On average, the RME exposure and the dose to risk conversion for road construction workers using PG are likely to overestimate risk.

Similarly, the highest RME to a resident living near a road (assuming the resident lives in a home located 50 feet or more from a road for 26 years) assuming the PG contains 27 pCi/g is approximately a 0.08 in 10,000 cancer risk, again, well below the PG reuse risk management goal of 3 in 10,000. Most residents living near roadways are located further than 50 feet from the edge of the road, and the RME exposure and dose to risk conversion are likely to overestimate risk.

The reclaimer scenario is not a RME since it is such a rare potential event, and should not be used in the risk management decision. Nonetheless, the risk assessment report calculated a risk using RME-type exposure input below the PG reuse risk management goal of 3 in 10,000.

D. Science Policy Assumptions and Uncertainties are Taken into Account in the Final Risk Management Decision

1. Overview

Each of the factors EPA considers in its risk management decision has sensitivities, variabilities, and uncertainties. EPA specifically considered uncertainties and other nonrisk factors in its 1989 and 1992 decisions on acceptable alternative uses of PG.[75]

A recent NAS report recommended incorporating uncertainty analysis, which was broadly defined to include sensitivities, variability, and various other uncertainties, into EPA decisions.[76] This NAS report recommends that "uncertainty analysis" be "designed on a case-by-case basis."[77] EPA considered uncertainties in previous risk calculations and decisions concerning

[77] *Id.*

alternative uses of PG.[78] However, combining RME with the inherent uncertainties in the dose to risk conversion factors can yield risks that are overly conservative compared to actual risks.

Science policy influences both the exposure calculation and the cancer potency and noncancer risk factors that convert the exposure to risk. The EPA decision makers and the public need to understand how policy influences the risk calculation. Put simply, regulatory risk is not the same as actual harm. Unduly conservative risk calculations do not serve the public, since they divert limited resources to issues that present less risk. Science policy based on accumulations of conservative assumptions, including extra layers based on uncertainties, can distort risk estimates and undermine the value and credibility of risk management decisions.

2. **Measurement Uncertainty**

Each calculated risk depends upon how sensitive the calculation is to changes in the measurements and input values used in any risk assessment. Risk is assumed to be linearly proportional to dose and the length of exposure. For example, if the concentration of radionuclide in PG increases by 10%, the dose (and, therefore, the risk) increases by 10%. Similarly, if the length of exposure increases by 20%, the total dose increases by 20%.

3. **Variation by Location**

Some of the inputs to risk assessments naturally vary. For example, the average radioactivity level in PG stacks depends upon the source of the phosphate ore and other site specific factors. This risk assessment assumed average radioactivity levels of 27 pCi/g. However, the average level of radioactivity in some PG stacks may vary from less than 10 pCi/g to 35 pCi/g, and even at levels of 35 pCi/g, the Risk Assessment shows these doses are safe.[79] Again, dose is directly proportional to the radioactivity level.

4. **The Influence of Exposure Policies**

It is well settled that exposure is not sufficient to support regulation unless there is a significant risk.[80] Because empirical data are often not available, a 2013 National Academies of Science (NAS) report noted that EPA's risk assessment policies and practices rely heavily on default options or generic approaches.[81] These approaches can introduce high levels of uncertainty into risk assessments.

---

[78] EPA PG Workbook, *supra* note 5, at 5.

[79] Based on the risk assessment, PG with radiation levels a couple of times greater than 27 pCi/g may still be utilized for road construction. In fact, an average radiation level of 148 pCi/g corresponds to EPA's risk management goal of 3 in 10,000.

[80] "When the administrative record reveals only scant or minimal risk of material health impairment, responsible administration calls for avoidance of extravagant, comprehensive regulation. Perfect safety is a chimera; regulation must not strangle human activity in the search for the impossible." *Industrial Union Dep't. v. API*, 448 U.S. 607, 642 (1980). *See NRDC v. EPA*, 1987, *supra* note 41, at 1164-65.

[81] Uncertainty in Environmental Decisions, *supra* note 76, at 58, *available at* https://www.nap.edu/read/12568/chapter/4#58. *Also see* National Research Council, Science and Judgment in Risk Assessment, 65 (1994), *available at* http://www.nap.edu/openbook.php?record_id=2125&page=65 and the General

As noted above, the "intent of the RME is to estimate a conservative exposure case (i.e., well above the average case) that is still within the range of possible exposures."[82] A NAS Committee reviewing EPA's regulation of technologically enhanced naturally occurring radioactive material (TENORM) recommended that EPA "should use exposure and dose risk assessments that are 'reasonably realistic'" in developing standards for exposure to the various types of low level naturally occurring radiation.[83] The Committee defined "reasonably realistic" as "not....intended to greatly overestimate or underestimate actual effects for the exposure situation of concern" and EPA agreed with the Committee's recommendations.[84] Thus, by definition, RME exposures should be intentionally set at levels that are at the high end, but not an extreme worst case.

The use of defaults has been criticized by independent commentators for: (a) "lack of an adequate scientific basis;" (b) the fact that default "can mask the uncertainty;" (c) observations that defaults can be "overly conservative;" (d) the fact that cumulative impact of uncertainties is not well defined; and (e) concerns "whether there is any basis for believing that the upper-bound estimate for one substance has the same relation to the 'true' risk as it does for another substance."[85]

5. Risk Factor Policies and Uncertainties

EPA has long utilized (and courts have long upheld) the principle that a 1 in 10,000 risk level is "safe." As a unanimous *en banc* ruling of the Court of Appeals for the District of Columbia Circuit candidly noted, the basis for claiming harm from exposure to chemicals at extremely low environmental levels is more a function of "the rules of arithmetic rather than because of any knowledge" and there was "no particular reason to think that the actual line of the incidence of harm is represented" by the assumption selected by EPA.[86] This acknowledgment is also apt for the risks from radionuclides.

Accounting Office, Use of Precautionary Assumptions in Health Risk Assessments and Benefits Estimates, GAO-01-55, 7 (October 2000).

[86] *NRDC v. EPA*, 1987, *supra* note 41, at 1165.

ED_005285_00000284-00038

The 2013 NAS noted that:

> EPA originally selected the linear, no-threshold default as a "conservative" or "health-protective" policy choice because it assumes that there is no dose below which risks are not increased. It is likely to generate the highest, or upper-bound, risk estimate consistent with the data; the actual risk almost certainly will not exceed the upper bound and will likely fall below it.[87]

Use of the ICRP value (the value proposed by the international institution whose purpose is to provide such advice) is supported by several factors:

First, ICRP is an expert advisory body that offers its recommendations to regulatory and advisory agencies, mainly by providing guidance on the fundamental principles on which appropriate radiological protection is based. The 2007 recommendation was produced "after eight years of discussions, involving scientists, regulators, and users all around the world."[88]

Second, the Petition's use of the ICRP dose to risk conversion factor is consistent with EPA's radiation risk assessment factors and procedures. For example, the EPA 2011 radiation guidance[89] provides cancer risk factors for uniform whole-body exposures of low-dose gamma radiation to the entire population, essentially the same dose to risk conversion range derived by the ICRP.

Similarly, as noted above, the organization chartered by the U.S. Congress in 1964 to, among other things, "develop … recommendations about …protection against radiation" (i.e., the United States National Council on Radiation Protection and Measurements (NCRP)) uses the same dose to risk conversion factor as the 2007 ICRP.[90]

Third, the international scientific and regulatory communities have widely adopted the ICRP recommendations.[91]

See UNSCEAR, Report of the United Scientific Committee on the Effects of Atomic Radiation, 8 and n. 17 (2010) (includes Scientific Report: summary of low-dose radiation effects on health, 2011) (UNSCEAR Report).

ED_005285_00000284-00039

Fourth, the International Atomic Energy Agency (an organization in which the U.S. is a member and helped establish) and the European Union (as well as each of its member countries) utilized a 1 millisievert (1 mSv) per year acceptable level of radiation exposure, which has been widely adopted by the international community, such as the IAEA and EU regulations. This corresponds to a 26-year total dose of 26 mSv (i.e., 2,600 mrem).

The ICRP approach is more stringent than the large, and growing, body of scientific literature that radiation risks have a threshold. Also, in 2015, a U.S. Nuclear Regulatory Commission (NRC) Advisory Committee acknowledged that:

> There is a large, and growing, body of scientific literature as well as mechanistic considerations which suggest that 1) the LNT model may overstate the carcinogenic risk of radiation at diagnostic medical, occupational, and environmental doses and 2) such low doses may, in fact, exert a hormetic (i.e., a beneficial or protective) effect.[92]

The United Nations Scientific Committee on the Effects of Atomic Radiation notes that below doses of 100 to 200 mGy (roughly equivalent to 10,000 to 20,000 mrem), "[e]pidemiological studies alone are unlikely to be able to identify significant elevations in risk."[93]

Because, as a matter of policy, neither EPA nor the Nuclear Regulatory Commission has changed its "no threshold" default assumptions, this Petition does not seek to go beyond the widely accepted ICRP value. In reality, the actual risk may be lower.

E. Comparison of Radioactivity Levels from Use of PG and Naturally Occurring Background

Each exposure scenario we assessed results in a radiation dose well below the annual natural background level. The annual background level of naturally occurring radiation is 310 mrem.[94] For a 26 year period, the cumulative dose is 8,060 (310 mrem times 26), thus the total dose for a nearby resident (16 mrem) given this PG use is 0.2% of the cumulative natural background dose levels (16 divided by 8,060). Background levels of radiation are often considered in governmental decisions. For example, EPA's PG Workbook compares the risk from use of PG to background levels of radiation.[95] When the calculated risk for receptors in a risk assessment is lower than background, it is a relevant factor in the risk management decision.

F. EPA Policy Supports Recycling of Wastes and Waste Residuals

EPA's 1989[96] and 1992[97] risk management decisions concerning alternative uses of PG took into account the Agency's overarching policy of supporting recycling. Since 1992, EPA has increased its emphasis on adopting sustainability policies.

EPA has prioritized policies to encourage recycling of byproducts and other materials.[98] Similarly, the U.S. Department of Agriculture also has guidance on using reclaimed materials in road construction.[99] Such recycling decreases raw material costs for companies and government entities that use the PG material, increases beneficial land use, reduces long-term maintenance costs, and avoids with respect to coal ash, site-specific potential environmental risks from long term storage of PG. For example, EPA states that:

> Beneficial use is the recycling or reuse of coal ash in lieu of disposal. For example, coal ash is an important ingredient in the manufacture of concrete and wallboard, and EPA supports the responsible use of coal ash in this manner. This final rule supports the responsible recycling of coal ash by distinguishing beneficial use from disposal.[100]

EPA recently concluded that:

> [E]nvironmental releases of COPCs from CCR fly ash concrete and FGD gypsum wallboard during use by the consumer are comparable to or lower than those from analogous non-CCR products, or are at or below relevant regulatory and health-based benchmarks for human and ecological receptors. Thus, EPA supports the continued beneficial use of coal fly ash in concrete and FGD gypsum in wallboard. Furthermore, the Agency believes that these beneficial uses provide significant environmental and economic benefits, and opportunities to advance Sustainable Materials Management (SMM).[101]

---

[96] 1989 Rule, *supra* note 2.

[97] 1992 Rule, *supra* note 16, at 23,306.

[98] "Sustainable Materials Management (SMM) refers to the use and reuse of materials in the most productive and sustainable way across their entire life cycle. On a broader scale, SMM looks at social, environmental and economic factors to get a more holistic view of the entire system. The benefits of maximizing this connection include conserving resources, reducing waste, slowing climate change, and minimizing the environmental impacts of the materials we use." EPA, Advancing Sustainable Materials Management: 2016 Recycling Economic Information (REI) Report, 2 (2016), *available at* https://www.epa.gov/sites/production/files/2017-05/documents/final_2016_rei_report.pdf.

[99] Reclaimed Materials and Their Applications in Road Construction, *supra* note 71.

[100] EPA, Frequent Questions about Beneficial Use of Coal Combustion residuals (CCR) (last updated March 26, 2019) *available at* https://www.epa.gov/coalash/frequent-questions-about-beneficial-use-coal-ash.

[101] EPA, Coal Combustion Residual Beneficial Use Evaluation: Fly Ash Concrete and FGD Gypsum Wallboard, 5-25 (2014), *available at* https://www.epa.gov/sites/production/files/2014-12/documents/ccr_bu_eval.pdf (Coal Cumbustion Residual Beneficial Use Evaluation).

The use of CCR for beneficial use in road construction is analogous to and supports the Office of Air and Radiation's approval of the use of PG in road construction. More generally, approval of the use of PG in road construction is consistent with EPA's policy of encouraging recycling.

G. Naturally Occurring Background Radioactivity and Metals are Present Widely in the Environment, Including Existing Road Construction Materials

Many consumer products contain radioactive components (smoke detectors, clocks and watches, older camera lenses, older gas lantern mantles, older televisions and computer monitors, sun lamps and tanning salons, ceramic materials such as tiles and pottery, glassware, and some EXIT signs, among other products).[102] Most consumer products contain metals. Similarly, "[r]adioactive materials (including uranium, thorium, and radium) exist naturally in soil and rock."[103] Essentially all air contains radon and many types of soil and natural rock emit radiation.[104] In addition, virtually all road construction materials contain radioactivity and metals.

Coal ash, fly ash, bottom ash, natural gypsum, and other common construction materials contain radioactive material (see Table below).[105]

A 2014 evaluation of coal ash beneficial uses concluded that:

> All of the existing evaluations identified concluded that radiation exposures from fly ash concrete are not a major source of concern. Several of these existing evaluations compared fly ash concrete to analogous products and found that the potential exposures do not represent an appreciable addition to the background radiation that the general public is subjected to on an annual basis. Naturally occurring radionuclides are present throughout the environment in food, air, water, soil, consumer products, and even the human body. All natural resources used in building construction (e.g., cement blocks, bricks, granite, soil, rocks) contain some trace level of naturally occurring radionuclides. For example, the USGS concluded that "the radioactivity of typical fly ash is not significantly different from that of more conventional concrete additives or other building materials such as granite and red brick." The NCRP concluded that exposures from living in concrete buildings containing fly ash are "similar to calculations made for individuals living in a brick and masonry home. Consequently, it is assumed that the use of [coal ash] in building materials has not substantially increased the average dose to an individual in the population residing in a building constructed with brick or masonry materials."[106]

[105] EPA Report to Congress Re: TENORM, *supra* note 37, at Appendix A.

[106] Coal Combustion Residual Beneficial Use Evaluation, *supra* note 101, at 1-7.

The United Kingdom Health Protection Agency "concluded that exposures to '…members of the public from the use of [fly ash] in building materials is negligible.'"[107]

Thus, the appropriate risk management consideration is not whether PG has a low level of radioactivity or metals, but whether the risk is below the EPA PG risk management goal of 3 in 10,000.

H. Use of PG For Roadway Construction Provides a Net Economic Benefit and is Consistent with the Administration's Regulatory Reform Policies

A detailed report explaining the various economic benefits to be expected from approval of PG use in road construction will be submitted shortly in support of this Petition.

The Petition is consistent with Presidential Executive Orders that encourage: (a) reducing unnecessarily burdensome and costly regulation;[108] (b) maximizing the use of goods, products and materials produced in the U.S.;[109] and (c) encouraging innovative strategies and trade policies.[110]

I. Other Benefits to Eliminating PG Stacks

Construction and maintenance of PG stacks are large engineering projects. There are environmental and actuarial risks presented by any such construction project. The approval of PG for use in road construction will reduce future potential risk by limiting the size of existing and potentially eliminating the need for new PG stacks.

[108] Presidential Executive Order on Reducing Regulation and Controlling Regulatory Costs, Executive Order 13771 (Jan. 31, 2017).

[109] Presidential Executive Order on Buy American and Hire American, Executive Order 13788 (April 18, 2017).

[110] Presidential Executive Order on Establishment of Office of Trade and Manufacturing Policy, Executive Order 13797 (April 29, 2017).

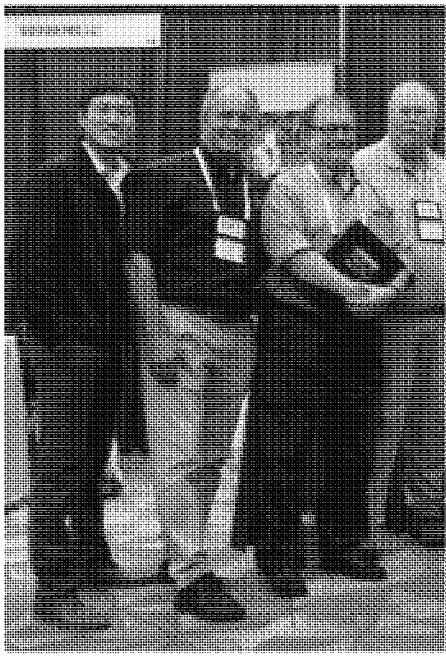
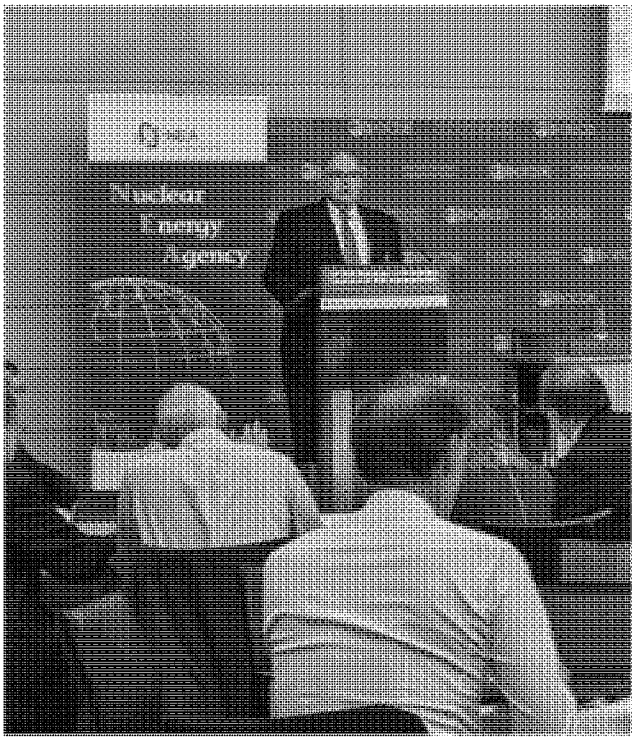
ORIA Weekly – September 27, 2019

RECENT EVENTS



RPD and Regional Staff along with ORIA Director Attended Naturally Occurring Radioactive Material (NORM) IX Symposium – See9/20/19 ORIA Weekly for more details



RPD's Boyd and Wieder Participated in the Nuclear Energy Agency (NEA) Workshop on Stakeholder Involvement: Risk Communication – See 9/20/19 ORIA Weekly for more details.

- **RPD's Nesky Participated in U.S.-Japan Bilateral Emergency Management Working Group** – See 9/20/19 ORIA Weekly for more details.
- **IED Convened the Asthma Community of Practice Meeting** – See 9/20/19 ORIA Weekly for more details.

- **IED's Mitchell Participated in the President's Task Force Meeting on Environmental Health Risks and Safety Risks to Children –** See 9/20/19 ORIA Weekly for more details.

RadNet Report for the Week of September 16, 2019

Overall monitor operational percentage was 90.3%. This is above the operational goal of 80%.

UPCOMING EVENTS (As of September 27)

Indoor Air Quality

- **IED's Hurst and Johnson to Present Indoor airPLUS Leader Awards During National Sustainable Building Summit:** On October 1-3, in Denver, CO, IED's Nick Hurst and Aaron Johnson will participate in the 2019 Energy and Environmental Building Alliance (EEBA)

Summit. EEBA is among the oldest and most respected residential building education organizations in the country. Approximately 400 industry homebuilders, home energy raters, and product manufacturers will attend the summit to share best practices for healthy, energy-efficient design and construction techniques. Indoor airPLUS is a sponsor for the summit's education sessions. Nick will deliver a presentation on radon-resistant construction, moderate a panel discussion on indoor air quality, and serve as a Technical Advisor in the EEBA Board Meeting. Nick and Aaron will also present the 2019 *Indoor airPLUS Leader Awards* to ten winning builder and rater partners and highlight their participation and achievements over the last year. At the end of the award ceremony, the Indoor airPLUS "Leaders of the Year" in the builder and rater category will be publicly announced and recognized.

- **IED's Schools Team to Host 3-part Webinar Series on IAQ and Healthy Green Cleaning in Schools:** On October 3, during Children's Health Month, the IED's Schools Team will rebroadcast the first of three popular IAQ and Healthy Green Cleaning in Schools webinars entitled, "*Clean Bill of Health; How Effective Cleaning and Maintenance Can Improve Health Outcomes in Your School*". The webinar will teach participants how to establish cleaning and maintenance training programs to increase efficiency and protect the health of the cleaning staff. School staff will learn how to train and prepare staff to implement a preventive maintenance plan to reduce costs and improve health by using effective cleaning practices. These webinars are part of the IAQ in Schools Master Class and IAQ Knowledge to Action Professional Series.

- **Tribal Air Monitoring Support (TAMS):** The week of September 30, in Washington, DC, NCRFO's Farshid Farsi is attending EPA's Tribal Air Coordinator's (TAC) Meeting. This meeting is an open forum for the regional offices to share insights regarding their work with their tribal professional constituents. The TAMS Center will provide a presentation regarding TAMS technical services available to the tribes and discuss opportunities to improve communications with the TACS in providing those services to the tribes.

Radiation Protection and Emergency Response

- **RPD's DeCair to Attend Nuclear Energy Agency (NEA) Expert Group on Recovery Management:** On October 1-2, in Bristol, UK, RPD's Sara DeCair will co-facilitate a two day meeting of an Organization for Economic Co-operation and Development, NEA-sponsored working group on best managing the long term recovery after a radiological accident or attack. A group of experts from numerous countries around the world will share real-world experiences, best practices and pitfalls to avoid and pull together a set of recommendations aimed at improving future disaster recoveries. Recent experience with garnering more public trust and ongoing radioactive waste management efforts in Japan will be a key feature of the discussion. The end result of this effort is anticipated to be a summary of best practices and recommendations published by the NEA.

- **New Facility to be Shown at Continuity of Operations (COOP) Open House:** On October 3 and 9, in Mt. Weather, Virginia, OAR Emergency Relocations Group personnel will attend open house information sessions at the new EPA COOP facility. COOP Personnel are encouraged to attend to verify their badges and become familiar with the facility.

- **RPD Staff to host meeting with The Fertilizer Institute (TFI):** On October 2, in Washington, DC, the Radiation Protection Division will host a meeting with the Fertilizer Institute (TFI). TFI

is developing a risk assessment addressing the use of phosphogypsum as a road base. If approved, this risk assessment could be used to support an application for use of phosphogypsum under the Subpart R NESHAP.

On Wednesday, October 2, RPD will host a meeting with the Fertilizer Institute (TFI). TFI is developing a risk assessment addressing the use of phosphogypsum as a road base. If approved, this risk assessment could be used to support an application for use of phosphogypsum under the Subpart R NESHAP. Representatives of CMWR, CST, and CRIO will participate.

Jon: TFI

If you have not already, please submit an item for the weekly on the TFI meeting. Make sure you copy Rick, as Stefanie is on travel through the end of the week.

Also, please provide Patricia with a list of expected attendees so that she can coordinate with security. Do we need an agenda?

Thanks.

Dan

Subject: Entries for the ORIA weekly

Please send Rick only any items that you have for the ORIA Weekly no later than noon on Wednesday, September 25. I will be out of the office, and will not see your message if you send your entry only to me.

Ideally, we'd like to feature events from the following time periods:

Events that recently took place: September 21 – September 27
Upcoming events: September 28 – October 4

ORIA Weekly – January 24, 2020

RECENT EVENTS

- **IED's Rowson Participated in an IAQ Interview for Native America Calling:** On January 21, IED's Dave Rowson participated in a live radio interview hosted by Native America Calling. This broadcast hosts national conversations about issues specific to Native communities and is designed to improve the quality of life for Native Americans. Native America Calling is heard on nearly 70 public, community and tribal radio stations in the United States and in Canada. The focus of this week's program was tribal indoor air quality. Additional panelists were Wilfred Nabahe, chairman of the National Tribal Air Association and Priyanka Pathak, a public health professional and former EPA Region 9 indoor air quality lead.

- **IED's Hurst Participated in the International Builders' Show** – See 1/17/20 ORIA Weekly for more details.

- **IED's Johnson Attended the Energy-Efficient Economy Conference on Health, Environment, and Energy** – See 1/17/20 ORIA Weekly for more details.

- **RPD's Santillan Spoke at the University of North Carolina (UNC) and Toured Duke University's Triangle Universities Nuclear Laboratory (TUNL):** On January 23-24, in Chapel Hill, NC, RPD's Jay Santillan met with UNC students and faculty and presented a talk during the UNC weekly colloquium. Jay's talk was entitled "Regulatory Perspectives on Actinide Geochemistry at the Waste Isolation Pilot Plant Radioactive Waste Facility, Carlsbad, New Mexico, USA." Santillan also traveled to Durham, NC to visit with students and faculty at Duke University and to tour the TUNL facility.

- **RPD Staff Met with The Fertilizer Institute (TFI):** On January 23-24, in Washington, DC, RPD staff will meet with representatives of the Fertilizer Institute (TFI), which represents producers of phosphate fertilizer. Meetings discussed TFI's risk assessment and application to use phosphogypsum in road construction. The Thursday meeting will focus on technical issues, and the Friday meeting on legal and policy issues.

RadNet Report for the Week of January 13, 2020

Overall monitor operational percentage was 89.7%. This is above the operational goal of 80%.

UPCOMING EVENTS (As of January 24)

Radiation Protection and Emergency Response

- **RPD's Feltcorn to Conduct Evaluation of Tier 1 Request:** On January 27-29, near Idaho Falls, ID, RPD's Ed Feltcorn, of the Waste Isolation Pilot Plant (WIPP) Waste Characterization Inspection Team, will conduct an evaluation of a Tier 1 request to add a waste stream stored at the Naval Reactors Facility at the Idaho National Laboratory. This evaluation will determine if the waste is compliant with 40 CFR 194 requirements.

- **ORIA Staff to Attend Health Physics Society (HPS) Midyear Technical Meeting:** On January 27-29 in Bethesda, MD, RPD staff will attend the HPS midyear technical meeting. ORIA Office Director Jon Edwards will speak for the opening session and staff members David Stuenkel, Angela Shogren, Gary Chen and Jessica Wieder will give talks, present a poster and/or chair sessions at the meeting. Staff members Jon Nagata, Brian Littleton, Lowell Ralston, Jon Walsh, Phil Egidi and Sara DeCair will participate in technical sessions on the latest in health physics research, applications and policy.

- **RPD's Snead to Attend International Atomic Energy Agency (IAEA) Workshop on the Arrangements for the Termination of a Nuclear or Radiological Emergency:** On January 27-31, in Ottawa, Canada, RPD's Kathryn Snead will represent USEPA at the North American regional IAEA Workshop on Arrangements for the Termination of a Nuclear or Radiological Emergency. The workshop will discuss arrangements needed to ensure the smooth and timely resumption of normal social and economic activity after a nuclear or radiological emergency.

- **RPD's Hallam to Attend Mars 2020 Radiological Contingency Planning (RCP) Meeting:** On January 28-30, in Cape Canaveral, FL, RPD's Chris Hallam will participate in the fourth of a series of Radiological Contingency Planning events to support NASA's Mars 2020 mission which will employ a Multi-Mission Radioisotope Thermoelectric Generator (MMRTG) containing plutonium. The meeting is designed to foster interagency coordination for the scheduled launch in July 2020, and will be attended by Federal, state and local stakeholders. The meeting will review the results of the November 2019, Command Post Exercise, conduct a review of updated plans, procedures, and checklists, and solidify the deployment schedule for agencies actively participating in the launch.

Indoor Air Quality

- **IED's Mitchell To Participate in the annual Engineers in Technical and Humanitarian Opportunities of Service (ETHOS) Conference:** On January 24-26, in Seattle, WA, IED's John Mitchell will participate in the annual Engineers in Technical and Humanitarian Opportunities of Service (ETHOS) Conference. John will join with more than 100 household energy community members to discuss stove design and performance, laboratory and field-testing results, development and dissemination of cookstove standards, and project activities and research initiatives. John will facilitate sessions on the development and dissemination of cookstove standards through the International Organization for Standardization ISO process. While in Seattle, John will meet with staff from the Gate's Foundation's Global Good initiative to discuss their household energy activities and working together in the coming years.

Subject: RE: FAQ Question 8 - volume and number of stacks

It's also a bit confusing, on page 28 of the Revised Petition, TFI says 46 million tons of PG is produced each year.

Then on page 11 of the economic analysis, TFI says:

Hi Patricia,

Jon has cleared on the TFI package. Could you please take your editorial pen to these memorandum/letter documents, adding letterhead where needed and formatting properly? Send them back and then I can get you the whole package including that long list below for submission to CMS. We're not quite ready for CMS yet, however, so no need to look at that today.

Subject: TFI Materials for Your Review

Jon:

Attached for your review are the components of the package for approval of the TFI request for other use of phosphogypsum. Files include:

1. Transmittal Memo from you to Anne Austin, recommending that she forward the package to the Administrator;
2. Action Memo from Anne to the Administrator, recommending his signature on the approval letter and Federal Register notice;
3. Letter from the Administrator to TFI approving the request;
4. Federal Register package, including;
    - Federal Register notice for Administrator signature;
    - Typesetting request and screenshot of funding information from Compass;

    - Action Information form;
5. 1-page summary (similar to the document provided for the Administrator briefing next week);
6. Communications plan; and
7. Press release.

I believe you already have the communications plan and press release, which have also been shared with OAR communications. Charles Starrs (OGC) has provided some comment on these two documents, which will need to be reviewed with CRIO staff. Charles' comments on the other documents have been addressed.

Please let Lee or me know if you have questions or comments. Thanks.

Dan

ENVIRONMENTAL PROTECTION AGENCY

[EPA-HQ-OAR-2020-0442; FRL–10014-36-OAR]

Approval of the Request for Other Use of Phosphogypsum by The Fertilizer Institute

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice.

SUMMARY: The Environmental Protection Agency (EPA) is approving, subject to certain conditions, a request by The Fertilizer Institute for use of phosphogypsum in government road projects. This decision and supporting information is being made available to the public through this notice. Under the Clean Air Act, the EPA may approve a request for other use of phosphogypsum if it determines that the proposed use is at least as protective of human health as placement in a stack, which is the designated management method. With this approval, and in accordance with its terms and conditions, government entities may use phosphogypsum for road construction projects.

DATES: [Insert date of publication in the Federal Register.]

FOR FURTHER INFORMATION CONTACT: Jonathan P. Walsh, Radiation Protection Division, Office of Radiation and Indoor Air, Mail Code 6608T, Environmental Protection Agency, 1200 Pennsylvania Ave., NW, Washington, DC 20460; telephone number: (202) 343-9238; fax number: (202) 343-2304; email address: walsh.jonathan@epa.gov.

SUPPLEMENTARY INFORMATION:

I. General Information

A. How Can I Get Copies of This Document and Other Related Information?

1. *Docket.* The EPA has established a docket for this action under Docket ID No. EPA-HQ-OAR-2020-0442. Publicly available docket materials are available either electronically through www.regulations.gov or in hard copy at the Air and Radiation Docket in the EPA Docket Center, (EPA/DC) EPA West, Room 3334, 1301 Constitution Ave., NW, Washington, DC. The EPA Docket Center Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566-1744, and the telephone number for the Air and Radiation Docket is (202) 566-1742.

2. *Electronic Access.* You may access this Federal Register document electronically from the Government Printing Office under the "*Federal Register*" listings at FDSys (http://www.gpo.gov/fdsys/browse/collection.action?collectionCode=FR).

II. Background and Overview of Decision

Phosphogypsum stacks are large piles of waste from wet acid phosphorous production. There are more than 60 stacks of phosphogypsum located in 13 different states. The majority of these stacks are located in the southeastern region of the United States. Because the phosphate ore used to produce the phosphoric acid contains relatively high concentrations of uranium and radium, phosphogypsum stacks also contain high concentrations of these elements. The presence

of radium in the stacks causes them to release radon gas into the atmosphere.

The EPA regulates the management of phosphogypsum based on its elevated levels of radium and its decay products, including radon gas, which is classified as a hazardous air pollutant under the Clean Air Act. As required by 40 CFR part 61, subpart R (hereafter "Subpart R"), phosphogypsum must be disposed of in engineered piles, called stacks, with the exception of limited use for agricultural and research purposes. In addition, applicants may request approval of other uses of phosphogypsum by following the process prescribed in 40 CFR 61.206.

A. The EPA's 1992 Risk Assessment

The EPA initially established the requirement that phosphogypsum be placed into stacks without any exceptions (54 FR 51674, December 15, 1989). In response to petitions for reconsideration, the EPA re-evaluated the risks of selected applications of phosphogypsum against the risks from stacking (57 FR 23305, June 3, 1992).[1] The EPA determined that the use of phosphogypsum in limited agricultural and indoor research activities could be as protective of human health, in the short- and long-term, as stacking. These approved uses were incorporated into Subpart R at 40 CFR 61.204-205.

The EPA also assessed the use of phosphogypsum in road construction. While the risks were found to be acceptable from most of the exposure scenarios analyzed, the potential risks to residents of dwellings constructed on an abandoned road were calculated to be unacceptably high. The EPA therefore did not approve road construction as a categorical use of phosphogypsum. The EPA did, however, define in 40 CFR 61.206 a process to request approval of other uses of phosphogypsum, including a risk assessment demonstrating that the proposed use is at least as protective of human health, in the short- and long-term, as placement in a stack.

[1] 'Potential Uses of Phosphogypsum and Associated Risks: Background Information Document," EPA 402-R92-002, May 1992.

As stated in the preamble to the final rule, the measure of protectiveness is lifetime risk of fatal cancer to individuals. In connection with the removal of phosphogypsum from stacks for authorized uses, the EPA incorporated sampling, certification, and record-keeping requirements into Subpart R at 40 CFR 61.207 through 61.209.

B. Request by The Fertilizer Institute

On October 15, 2019, The Fertilizer Institute (TFI) submitted its initial "Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 CFR 61.206," requesting that EPA approve the use of phosphogypsum in road construction. Subsequently, on April 7, 2020, TFI submitted, on behalf of its members that own or operate phosphogypsum stacks, a revised request: "Revised Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 CFR 61.206: Use in Road Construction Projects Authorized by Federal, State and Local Departments of Transportation or Public Works".

TFI requested that phosphogypsum be approved specifically for government road projects authorized by federal, state and local Departments of Transportation (DOT) or Public Works (PW), and conducted as part of a government road project using appropriate, generally accepted road construction standards and specifications such as ASTM,[2] Federal Highway Administration, federal or state DOT standards and specifications, or standards developed or approved in consultation with the appropriate regulatory DOT or PW authorities. Notably, as envisioned by the request, the submitter of the request (TFI) would not be the entity using the phosphogypsum, although its members may supply the phosphogypsum to the end user (i.e., the government agency responsible for the road construction project). To address this situation, the terms and conditions of the approval require that the phosphogypsum supplier (stack owner or

[2] Formerly the American Society for Testing and Materials, now ASTM International.

operator) and the end user each provide information to the EPA, as appropriate, prior to removal of phosphogypsum from the stack.

TFI estimates that the cost of transportation would make the use of phosphogypsum uneconomical at distances greater than about 200 miles from a stack.[3] In that case, the regional distribution of phosphogypsum stacks suggests that its use for road construction would likely be concentrated in the southeastern part of the country but could also occur in western states such as Idaho and Wyoming.

C. TFI's Risk Assessment

As required by Subpart R, TFI submitted a risk assessment as part of its request.[4] The risk assessment assessed potential exposures to individuals in various scenarios involving road users, nearby residents, and road construction workers. TFI's exposure scenarios and modeling approaches were largely consistent with the EPA's 1992 analysis, as were the overall results.

The EPA finds TFI's risk assessment to adequately demonstrate that the use of phosphogypsum in road construction will be at least as protective of human health, in the short- and long-term, as stacking.[5] However, as in 1992, the EPA remains concerned about potential exposures should the road become abandoned, particularly for a residence built on road material containing phosphogypsum. The EPA does not agree that TFI's assumptions in its analysis of this scenario, such as the use of radon resistant home construction techniques, could be relied upon to limit the potential risks to a future residential individual from such an occurrence. In this case, however, the EPA believes that this risk can be acceptably mitigated by including

[3] "Economic Analysis of Phosphogypsum Reuse," prepared for TFI by Policy Navigation Group, submitted as Appendix 6 to TFI's Revised Request, December 2019, page 19.
[4] "Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum," prepared for TFI by Arcadis Canada Inc., submitted as Appendix 2 to TFI's Revised Request, October 2019.
[5] "Review of the Radiological Risk Assessment Submitted in Support of Request for Approval of Other Use of Phosphogypsum," October 2019, The Fertilizer Institute.

appropriate terms and conditions in the approval.

In defining its request and exposure scenarios, TFI's risk assessment assumes certain limitations involving the construction and placement of roads. For example, phosphogypsum incorporated into the road base and the road surface is limited in its radium-226 concentration and is assumed to be mixed with other materials in limited proportions. The terms and conditions of the approval reflect these assumptions and limitations.

D. Terms and Conditions of the Approval

The EPA has determined that, subject to the terms and conditions summarized below, phosphogypsum may be removed from stacks and used in government road projects, as requested by TFI. This approval to use phosphogypsum in road construction does not authorize the removal of any phosphogypsum from any stacks or the use of any phosphogypsum for road construction unless and until the information required by the "Initial Conditions," below, is provided to EPA. Only after such information is provided to EPA, may phosphogypsum be removed from stacks and used in road construction, further provided that the conditions expressed in "Other Conditions," below, continue to be met. A complete listing of the terms and conditions applicable to this approval may be found in the approval letter.[6] Additional supporting documentation, such as the complete TFI request and risk assessment, are also in the docket.

1. Initial Conditions

Prior to the distribution and/or use of phosphogypsum for any government road project, the owner or operator of the stack from which phosphogypsum is to be distributed or the governmental entity responsible for building and maintaining the road, as appropriate, must submit to the Agency all information required by 40 CFR 61.206(b), as more specifically

[6] Letter from Andrew Wheeler, Administrator, Environmental Protection Agency, to Corey Rosenbusch, President and CEO, The Fertilizer Institute, Docket No. EPA-HQ-OAR-2020-0442.

described in the approval letter.

2. Other Conditions[7]

Subsequent to the provision of the initial required information to EPA, phosphogypsum may be used in government road projects in accordance with additional conditions, as stated in the approval letter, including, for example, conditions related to:

- Continued control, maintenance, and use of the road;
- Sampling, certification, and record-keeping requirements in 40 CFR 61.206(d) and 61.207 through 61.209;
- Construction of the road consistent with the assumptions, scenarios, limitations, and parameters analyzed in TFI's risk assessment, including an average radium content of no more than 35 pCi/g, no more than 2.25% PG by weight in surface pavement and no more than 50% PG by weight in the road base; and
- Notification and availability of information for the public and road construction workers on the use of phosphogypsum in the road project.

Any use of phosphogypsum not consistent with the terms and conditions and any other limitations set forth in this approval shall be construed as unauthorized distribution of phosphogypsum and may constitute a violation of or noncompliance with 40 CFR part 61, subpart R. This approval is pursuant to Subpart R promulgated under the authority of the Clean Air Act. This approval does not relieve TFI, phosphogypsum stack owners or operators or

[7] In addition to the information required by 40 CFR 61.206(b), as noted in connection with the "Initial Conditions," the "Other Conditions" include conditions associated with the requirements of 40 CFR 61.206(d) and 61.207-61.209; conditions inherent in the nature of or limitations or assumptions associated with TFI's request; and conditions imposed under the EPA's authority and discretion under 40 CFR 61.206(e). The EPA believes that these conditions are either required by 40 CFR part 61, subpart R or are reasonably appropriate to help provide continued assurance that the use is at least as protective as disposal of phosphogypsum in stacks and will ensure that the removal of phosphogypsum from stacks and use in government road projects will be consistent with TFI's request and will occur with public notice and appropriate information availability.

resellers, retailers, distributors, or end users or other entities handling, processing or using phosphogypsum of responsibility to comply with other applicable laws and regulations.

Andrew Wheeler,
Administrator.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

October 14, 2020

THE ADMINISTRATOR

Mr. Corey Rosenbusch
President and Chief Executive Officer
The Fertilizer Institute
425 Third Street, SW, Suite 950
Washington, D.C. 20024

Dear Mr. Rosenbusch:

The Fertilizer Institute, on behalf of its members that own or operate phosphogypsum stacks, has asked the U.S. Environmental Protection Agency to approve, under 40 C.F.R. § 61.206, the removal of PG from required stacks for use in government road construction projects. As discussed below, the EPA grants the request subject to certain conditions.

Background

On October 15, 2019, TFI submitted its initial "Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 C.F.R. § 61.206," requesting that the EPA approve the use of PG in road construction. Subsequently, on April 7, 2020, TFI submitted, on behalf of its members that own or operate PG stacks, a revised request: "Revised Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 C.F.R. § 61.206: Use in Road Construction Projects Authorized by Federal, State and Local Departments of Transportation or Public Works" (hereinafter the "Revised Request"). In evaluating TFI's submittals, the EPA generally has focused on the revised request, which we understand to be the most recent, complete version of TFI's request. The EPA has, however, evaluated TFI's request in light of all the materials submitted, including information submitted in connection with the initial request, as well as information subsequently submitted. The Revised Request asks the EPA to approve the use of PG in certain road construction projects:

> A determination by EPA, pursuant to 40 C.F.R. § 61.206, that PG containing up to an average of 35 picocuries per gram [pCi/g] may be used in road base, paving, and various combinations of road base and paving in Government Roadway Projects that meet the commitments of this petition and are:
>
> 1. Authorized by federal, state and local Departments of Transportation (DOT) or Public Works (PW), and

2. Conducted as part of a government road project using appropriate, generally accepted road construction standards and specifications such as American Society for Testing and Materials (ASTM), Federal Highway Administration (FHWA), federal or state DOT standards and specifications, or standards developed or approved in consultation with the appropriate regulatory DOT or PW authorities.

Revised Request at 23-24.

TFI submitted or resubmitted a number of materials with the Revised Request, including miscellaneous federal and state road construction specifications and requirements; a Summary of the Risk Assessment (previously submitted by TFI); a Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum prepared by Arcadis Canada Inc. on behalf of TFI (previously submitted by TFI); a technical memorandum prepared by Exponent on behalf of TFI relating to a chemical risk screening to evaluate potential risks associated with metals/metalloids in PG; responses – apparently prepared by Arcadis Canada Inc. on behalf of TFI – to various questions and comments from the EPA; a discussion by TFI of the results of sampling and radiological testing of samples of PG from 10 stacks in four states; an economic analysis by the Policy Navigation Group, on behalf of TFI, to estimate potential regulatory cost savings associated with using PG in road construction; information on the location of certain PG stacks in Florida, Louisiana, Wyoming and Idaho; a list of materials cited in the Revised Request and other items submitted by TFI. These submissions are identified in TFI's Revised Request as Attachment A and Appendices 1 through 8, respectively. Revised Request at 2-3 and Attachment A and Appendices 1-8.

A significant part of the Revised Request and related information submitted by TFI relates to TFI's assessment of the risks associated with the use of PG in road construction. TFI evaluated the risks under various scenarios, including risks to road construction workers, truck drivers transporting PG, road users, utility workers performing work on utilities at or under roads constructed with PG and residents living near roads constructed with PG. TFI assessed risk based on certain identified assumptions about the amount of PG used in road construction projects and on the amount of radium-226 in the PG used in road construction. With the assumptions used in TFI's risk assessment, TFI's calculated risks for the reasonably maximally exposed individual were no more than 0.5 in 10,000, less than the 3 in 10,000 risk that TFI maintains the EPA uses as the risk of the PG if left in the stack. See, for example, Revised Request, at 16 (Table 1). TFI's risk assessment concluded that the risk of using PG in road construction is low and using PG in road construction would be at least as protective as keeping PG in stacks.

The Revised Request notes the requirements of 40 C.F.R § 61.206, including the information that a request for approval of other uses of PG (other than keeping the PG in stacks) must contain. See, for example, Revised Request at 24-25. The Revised Request asserts that it has provided sufficient information for the EPA to determine whether the proposed use would be at least as protective as disposal of PG in stacks, suggesting that it has provided the information required by 40 C.F.R § 61.206(b)(1), (2), and (6)-(9). Revised Request at 50, footnote 123. The Revised Request essentially acknowledges that it has not provided the information required by 40 C.F.R § 61.206(b)(3)-(5) and (10) but suggests that the EPA approval may be "conditioned upon receipt" of such information. *Id.*

ED_005285_00000391-00002

The Revised Request includes discussion of various other considerations that TFI argues weigh in favor of supporting or allowing uses of PG, such as use in road construction, rather than simply requiring that PG be kept in stacks. Among these considerations are the following contentions: there has been significant growth in the industry and resulting significant increases in PG material generated that the EPA did not anticipate when generally requiring that PG be kept in stacks; the number and size of PG stacks have increased, as well as the costs to manage and maintain the stacks; other countries do not strictly require that PG be kept in stacks and more readily allow PG to be used for other purposes; and allowing other uses to be made of PG is consistent with the EPA's interest in "beneficial uses" of materials and with general EPA policies encouraging recycling.

Discussion

The EPA's *Clean Air Act* regulations at 40 C.F.R. Part 61, Subpart R, address concerns about radon emissions from PG. Subpart R generally applies to owners or operators of PG stacks and to "each person who owns, sells, distributes, or otherwise uses any quantity of phosphogypsum." 40 C.F.R. § 61.200. The basic requirement of Subpart R is that PG must be placed in stacks and may not be removed from stacks, except "as expressly provided." 40 C.F.R § 61.202. Subpart R provides three sets of exceptions under which PG may be removed from stacks: PG may be removed from stacks and used "in outdoor agricultural research and development and agricultural field use" under certain circumstances (40 C.F.R § 61.204); PG may be removed from stacks and used "in indoor research and development activities" under certain circumstances (40 C.F.R § 61.205); and, upon request, the EPA may approve the removal of PG from stacks and the use of PG for "other purposes" (40 C.F.R § 61.206). Relying on this "other purpose" approval authority, the Revised Request asks the EPA to approve the removal of PG from stacks for use in government road construction.

As the Revised Request acknowledges, a request for approval of the use of PG for other purposes must contain certain information, including information about the specific location(s) where the PG will be used. 40 C.F.R § 61.206(b)(1)-(10). The procedure also requires that a request be "signed and dated by a corporate officer or public official in charge of the facility." 40 C.F.R § 61.206(b)(10). A request must include, for example, the location – including mailing address – of each "facility" where any use, handling or processing of PG will take place. 40 C.F.R § 61.206(b)(3), (4). The Revised Request has provided the locations of PG stacks owned or operated by TFI member companies, locations where at least some of the use, handling or processing of the PG to be used in road construction may occur. The Revised Request has not, however, provided any specific location information where the ultimate requested use – road construction – will take place. In addition, to the extent that there may be intermediary locations (such as processing facilities or construction yards) between a PG stack and a road under construction with PG, the Revised Request has not identified any such intermediary locations. A request under 40 C.F.R § 61.206 for approval of other use of PG also must include information on the quantity of PG to be used by each "facility." The Revised Request provided information about the percentage of PG likely to be used in either roadbed or pavement but has not provided information on the quantity of PG to be used in each road construction project.

ED_005285_00000391-00003

The Revised Request has provided considerable information about the anticipated use of PG in road construction. The Revised Request has, for example, provided information about the types of roads that may be constructed using PG, how PG may be used and the road construction process. The Revised Request has provided information about the proposed average concentration of radium-226 in the PG to be used. Critically, the Revised Request assessed and estimated risks associated with the use of PG in road construction.

The agency may approve a request to use PG for some "other purpose" if the proposed distribution or use is at least as protective of public health, in the short and long term, as disposal of PG in a stack. 40 C.F.R § 61.206(c). In the event the agency approves a request to remove PG from stacks and use PG for other purposes, certain prescribed requirements must be met, including requirements set out in 40 C.F.R. §§ 61.206(d) and 61.209. These include requirements on the owner or operator of a stack from which PG is removed to determine radium-226 concentrations; on stack owners or operators and on PG sellers or resellers, distributors and end users to ensure proper preparation and maintenance of certification documents; and on end users to prepare and maintain various records. 40 C.F.R §§ 61.206(d) and 61.209. In addition, the EPA has the authority to impose additional terms and conditions. 40 C.F.R § 61.206(e).

Although the Revised Request has not provided complete information about the specific locations where roads will be built using PG and has not identified the specific quantity of PG to be used in road construction, the lengthy, detailed information provided by the Revised Request about using PG in road construction and the thorough risk assessment is sufficient information for the agency to determine whether use of PG in road construction is at least as protective as disposal in a stack, at least under the circumstances and conditions described in the Revised Request and reflected in the risk assessment. In light of the information provided by TFI, the nature of the request and the conditions identified below, the agency concludes that the additional information required as part of a request under 40 C.F.R § 61.206(b) – especially information on specific address locations where the PG may be used – is not essential to making the determination of whether the proposed use of PG would be at least as protective of public health as stacking.

In evaluating risks associated with using PG in road construction, the Revised Request used an average radium-226 concentration of 27 pCi/g. Revised Request at 20 and 51. (The Revised Request also extrapolated that, even if the average radium-226 was as high as 148 pCi/g, the use of PG in road construction would be still be sufficiently protective of public health, and the Revised Request requested a "concentration limit" – that is, the limit on the level of radium-226 that may be in PG used in road construction – of 35 pCi/g. See, for example, Revised Request at 28.) The risk assessment was also based on assumptions that, when PG is used in road bed material, it would comprise no more than 50 percent of the road bed material, by weight (the other material would be "soil"), and, when used in road surface material, PG would comprise no more than 2.25 percent, by weight, of the surface pavement. Revised Request at 19. As noted above, the Revised Request evaluated risks from the standpoint of various exposure scenarios, including exposure of: persons engaged in road construction or transportation of PG (truck drivers); nearby residents (residing no closer than 50 feet from the road); and utility workers. At the EPA's request, the Revised Request also addressed risks to persons living on abandoned, reused or reclaimed roads (the "reclaimer scenario"). Revised Request at 22-23. Under all these scenarios, the Revised Request, as calculated in the TFI risk assessment, indicated that the risks associated with using PG in road construction

would be significantly less than a lifetime risk of fatal cancer from radon emissions of 3 in 10,000 and that using PG in road construction would be at least as protective of public health as disposal of PG in stacks. *Id.*

As initially promulgated, Subpart R required "stacking" and did not authorize alternative uses of PG. In 1992, the EPA amended Subpart R to categorically authorize use of PG for agricultural or research and development purposes under certain circumstances and to establish a procedure to request approval of other uses of PG. See 57 Fed. Reg. 23305 (June 3, 1992). At that time, the EPA considered also categorically authorizing the use of PG in road construction, but the EPA decided not to do so because it concluded that "the use of phosphogypsum in road construction presents an unacceptable level of risk to public health." *Id.* That determination largely was based on a concern about the risks to people living in a house constructed on land where roads built using PG once existed. The EPA did not necessarily foreclose any or all use of PG in road construction, but simply declined, at that time, to categorically authorize – as for agricultural or research and development uses – use of PG in road construction.

The EPA agrees that for purposes of assessing whether other uses of PG will be at least as protective as disposing of PG in stacks or a mine (and consistent with the agency's overall risk management policies), the radiation risk associated with phosphogypsum stacks (or disposing of PG in mines) may be numerically interpreted as a lifetime risk of excess mortality no greater than 3 in 10,000 (3×10^{-4}) for any member of the public. The EPA's review of the Revised Request's risk assessment concludes that the use of PG in road construction, when conducted in a manner consistent with the methods and scenarios described in TFI's application and under the conditions stated herein, will not create risks in excess of this threshold.

Because the risks associated with the "reclaimer scenario" previously were of particular concern to the EPA, the EPA asked TFI to address those risks in its analysis, and the Revised Request specifically addressed that scenario. Although the Revised Request regarded such a scenario as "extreme" and "unlikely," it, nonetheless, examined the risk associated with the scenario and concluded that the risk is low and that using PG in road construction still would be at least as protective as stacking. While the TFI risk assessment indicates the risk to the reclaimer could be as protective as leaving the PG in the stack, the EPA has questioned some of the modeling assumptions used by TFI to generate the estimate for the reclaimer. TFI's risk assessment assumed, for example: the PG concentration under a home would be less than that of the road base; there would be a layer of clean soil between the PG and slab of the house; and there would be a vapor barrier. We do not believe that these assumptions can be relied upon to limit potential risks to a future residential reuser of an abandoned road constructed with PG. The EPA has, however, reevaluated the use of PG in road construction in light of the new information and analysis in the Revised Request and now concludes that the risks associated with the "reclaimer scenario" can be addressed with conditions associated with possible future reuse of roads constructed with PG (as noted below).

In accordance with the discussion, above, and subject to certain qualifications and conditions (stated below), the EPA determines that the Revised Request adequately demonstrates that the use of PG in road construction is at least as protective of public health, in the short and long term, as disposal of PG in stacks, and, subject to the same qualifications and conditions, PG

ED_005285_00000391-00005

may be removed from stacks and used in government road construction, as requested by TFI. Accordingly, subject to the following conditions, PG may be used in government road projects authorized by federal, state and local departments of transportation or public works, and conducted as part of a government road project using appropriate, generally accepted road construction standards and specifications such as ASTM, FHWA, federal or state DOT standards and specifications or standards developed or approved in consultation with the appropriate regulatory DOT or PW authorities. See Revised Request at 23-24.

This approval to use PG in road construction does not authorize the removal of any PG from any stacks or the use of any PG for road construction unless and until the information required by the "Initial Conditions," below, is provided to the EPA. After such information is provided to the EPA, PG may be removed from stacks and used in road construction, provided that the conditions expressed in "Other Conditions," below, continue to be met.

Initial Conditions

Prior to the distribution and/or use of PG for any government road project, the owner or operator of the stack from which PG is to be distributed or the governmental entity responsible for building and maintaining the road (the "end user"), as appropriate, must submit the following information to the agency, in writing, to the attention of the Director, Radiation Protection Division, U.S. Environmental Protection Agency, 1200 Pennsylvania Avenue, NW, Mail Code 6608T, Washington, D.C. 20460, and by email to radiation.questions@epa.gov:

a) Identification of the project and of the responsible government agency, including an authorized point of contact and complete mailing address;
b) Geospatial information describing the location and extent of the road construction project using PG and the physical address or geospatial coordinates of any facility where intermediate handling or processing of the PG will take place. This information may be provided as map coordinates or computer files compatible with geospatial software (e.g. .kml, .gpx, .shp);
c) The total quantity of PG expected to be used in each project, the source of PG (company and stack) and the average concentration of radium-226 in the PG to be used;
d) A description of the measures which will be taken to prevent the uncontrolled release of PG into the environment during transportation, handling and construction; and
e) Written confirmation that the road construction project (inclusive of supporting contractors) will comply with the following conditions set forth in this approval, signed and dated by the public official responsible for the road construction project.

Other Conditions

In accordance with 40 C.F.R § 61.206(d)(1) and 40 C.F.R § 61.207, the owner or operator of a stack from which PG is removed to be used in road construction must determine annually the average radium-226 concentration at the location in the stack from which the PG is removed.

ED_005285_00000391-00006

In accordance with 40 C.F.R § 61.206(d)(2) and 40 C.F.R § 61.208, the owner or operator of a stack from which PG is removed to be used in road construction and any subsequent distributor, retailer or reseller, shall prepare, make available and provide, and retain appropriate certification documentation and any subsequent purchaser or transferee of PG shall receive and retain appropriate certification.

In accordance with 40 C.F.R § 61.206(d)(3) and 40 C.F.R § 61.209, each stack owner or operator and end user facility must maintain appropriate records.

In accordance with the circumstances and qualifications associated with the Revised Request and, especially, the risk assessment performed in connection with the Revised Request, as well as the agency's authority under 40 C.F.R § 61.206(e) to impose terms or conditions:

In addition to other generally applicable engineering specifications, PG may only be used in government road construction (no private road building) of paved roads (no unpaved roads) and the road design must fall within the following limits:

a) Average radium-226 content of PG to be used in road base or pavement must not exceed 35 pCi/g;
b) Pavement may contain no more than 2.25 percent PG by weight;
c) Road base may contain no more than 50 percent PG by weight;
d) Road base containing PG may consist of one lift of up to 25 cm depth and not extend beyond paved areas of the road; and
e) A minimum 50-foot setback is required from the edge of the road to inhabited structures.

Roads constructed with PG may not be abandoned (or otherwise permanently cease to be used as a road) and used for other non-road purposes or uses, including the construction of structures on such former roads.

Any PG that is unused in the road construction or removed as part of road maintenance and not reincorporated into the road base must be returned to the stack.

Records required by 40 C.F.R §61.209(c) must be maintained by the end user facility (i.e. government agency) for the life of the road. The government agency shall make those records available for public review.

Prior to use of PG in a road project, the responsible government agency shall provide public notice that the planned road will use PG. This may occur as part of public outreach processes associated with the road project and must include an opportunity for the public to review road plans and risk assessment materials.

Workers involved in road construction shall be informed that PG contains elevated levels of naturally occurring radionuclides and instructed in proper industrial hygiene.

ED_005285_00000391-00007

Any use of PG not consistent with the limitations set forth in this approval shall be construed as unauthorized distribution of PG and may constitute a violation of or noncompliance with 40 C.F.R. Part 61, Subpart R. This approval is pursuant to Subpart R promulgated under the authority of the *Clean Air Act*. This approval does not relieve TFI, phosphogypsum stack owners or operators or resellers, retailers, distributors or end users or other entities handling, processing or using PG of responsibility to comply with other applicable laws and regulations.

If your staff has further questions, please reach out to Lee Ann B. Veal, Director of the Radiation Protection Division, at veal.lee@epa.gov or (202) 343-9448.

Sincerely,

Andrew R. Wheeler

Thank you to the team!

I have provided our responses to Charles for one final look. I will send to Kati once I get the all clear from Charles.

To answer lee's question on geographic location of the reporter – our reporter is writing for The Sun, a publication based out of Florida.

Hi Stef,

Thank you for this final look. My few comments are below. I modified the last response but kept the content.
Is the Sun media outlet in Florida, Britain or elsewhere?

Subject: FOR REVIEW | Afternoon Draft Answers to The Sun's Media Inquiry

Team,

There have been a lot of emails today about The Sun's media request. I have compiled the most up to date versions of all answers that I've seen to date. Please review the answers to all questions below and let me know if any changes are needed.

Thank you,
Stefanie

1. Are the underlying assumptions of risk of death due to radiation exposure based on studies of atomic bomb survivors? If not, where do they get the risk of fatal cancer numbers from?

Ex. 5 Deliberative Process (DP)

2. Why did the EPA not allow for public comment on this rule change? When is public comment required?

Ex. 5 Deliberative Process (DP)

3. By government road projects, does this mean just those with federal funding? Not state or local funding?

Ex. 5 Deliberative Process (DP)

4. Will these applications to the EPA come from the phosphate manufacturers or the governmental entity that wants to use the material in road building?

Ex. 5 Deliberative Process (DP)

5. Has the EPA received any applications yet?

Ex. 5 Deliberative Process (DP)

6. How much of an impact can the EPA estimate have on the problem of gypstack formation? Will manufacturers be taking directly off their existing stack or from new material being generated by the manufacturing plants?

Ex. 5 Deliberative Process (DP)

7. how does the EPA estimate the lifetime risk of exposure to the stacks? This is important because the EPA said the relative risk was the same.

Ex. 5 Deliberative Process (DP)

Yes, sorry, I have been on calls since we got off of our morning TFI call. The comms plan is attached. Within the comms plan is an extensive Q&A. I leave it up to you if you prefer to pass along the comms plan in full, or if you just want to snip out the Q&A and send that.

Charlene,

Lee asked if you could please provide the TFI press release below to the regional contacts tomorrow AM (10/15). Lee also expects that this will be discussed on Tuesday's call.

Jon, would you be available to speak for about 10 min on the Tuesday call to provide an update on TFI and today's action?

Thanks!

Subject: PLEASE READ: SMR Rulemaking and TFI Press Release Discussion with the Regions
Attachments: TFI response-Comms Plan_09 21 2020 .docx

Hello all,

We are scheduling a meeting on Monday, October 19, 2020 to discuss the following topics with the Regions:

- SMR Rulemaking – Lee Veal
- TFI Press Release – Jon Walsh/Tom Peake (**Link to Press Release**: https://www.epa.gov/newsreleases/epa-approves-use-phosphogypsum-road-construction)

On the RPP Call on Tuesday, October 20, 2020, we currently have a special guest, Kathy Held, from NCRP presenting on the call; therefore we have decided to have an off schedule meeting with the Regions on **Monday, October 19, 2020 from 2:15pm EST to 3:00pm EST** to allow time to discuss these topics without any time constraints.

Attached to this email you will find the TFI Communications Plan, which has an extensive Q&A, which will probably address some of your questions. If not, in preparation for the meeting on Monday, please send me in advance any questions you may have regarding these topics.

I hope all of you are available to attend the meeting on Monday and I look forward to receiving your questions in advance. Please look for an invite, which will contain the call-in information and the MS Teams link.

If I have mistakenly left someone off of this distribution, please feel free to forward as you find appropriate.

Thank you in advance,
Charlene

Hello,
Thank you for the discussion this morning.

Under the assumption that the Administrator will be signing the TFI approval letter, I took the version of the letter I received from Charles Starrs, OGC, on September 8, accepted the edits and put the text on the Administrator's letterhead.

Please edit this version.

Talk to you on Tuesday.

Subject: OP's edits to the draft FR
Attachments: TFI FR_Notice_of_availability_Aug 23 pb edits.docx

Hi all,

OP has completed their review of the draft we put into FR Dailies near the end of August. I've attached it to this e-mail; you'll see Stephanie's edits/comments in red. Everything they have is very minor. The docket number (EPA-HQ-OAR-2020-0442) is set and the signature block will have to be updated given the Administrator is now signing the package:

Andrew Wheeler
Administrator

If you have any questions on these edits, just let me know! Otherwise, we should be clear to send the completed package forward after we incorporate these edits and any others that may have come along with the numbers or anything else from OLEM.

Thanks,

Ray

HI Charles,

Thank you for the feedback on timing. Tom and I were able to connect, as well as Jon Edwards and I.

If you could review the technical document by the end of day tomorrow, Thursday, that would be a wonderful thing. Jon E is on similar timing, maybe even today.

Ex. 5 Deliberative Process (DP)

Tony and Stef,
We are going to need another day for the technical report to clear. It will certainly be complete before the FR is published.

Subject: Let's move the letter up
Attachments: Response to TFI-Draft Conditions Letter AA to TFI August 18.docx

Lee,
Dan and I had a discussion with Charles late yesterday afternoon and he made a revision based on that discussion and the draft we sent him earlier in the day.

In the draft attached I deleted the comments and made a couple of other minor edits. Charles said he was ambivalent about using "pages" in front of the page numbers, but since he deleted them once and they were mostly gone, I just deleted the several remaining but crossed out "pages" and did not put in the word anywhere. I did put in "footnote". ☺ I left the markup so you could see the changes.

I think we are done with it and it is ready for you to do a last look. Jon is coordinating with Ray on the FR notice and the team is finishing the FAQs for Stephanie's communication plan. I let Charles know we would be sending the FR notice to him when we got it ready. We also have the EPA technical review that will need to be reviewed, too, in the next week.

Subject: TFI Communications Plan

Good afternoon Lee,

Below is a SharePoint link to the Fertilizer Institute Communications Plan. This document heavily relied on input from the technical team, and has been reviewed by Jessica, Dan, and Tom. Prior to sending it to you, I addressed most of the comments from earlier reviews, including track changes suggested by previous reviewers. You will notice though, that

there are a small number of comments, placeholders, and reminders that I will need to address before the document is final.

Ex. 5 Deliberative Process (DP)

The next step in the review process would be for Jon and Andrea to review the package. Please let me know if and when you would like me to assist with shepherding the document to them. I would also understand if you wanted to pass it on directly.

Finally, and as always, please let me know if you have any questions.

Thank you,
Stefanie

Subject: EPA tech summary errata

Here is what I caught:

On p.5, in "Summary of Results", an error printed because the text refers to Table 1.

Footnotes for Table 2 bleed over the page

The final sentence of page 8 bleeds over, creating a nearly blank page.

Importance: High

Dear Jon, Dan, and Tom:

I created a document page with the supporting materials that will appear in the Docket upon publication. It includes a signed copy of Administrator Wheeler's letter, as TFI told Lee they had no problem with our putting on the website. Please review the page to ensure I got everything right, and provide me with any edits. We need to publish this tomorrow morning to answer the press inquiry due at 11 AM. (It will enable us to quickly answer or even avoid further inquiries).

Subject: RE: Request for additional information

It's really not a cold call. Jon is listed in the Federal Register as the contact, and as such, can reply directly to the questioner. This is a technical question, so there's no need to involve OPA if the press is not involved.

I think Jon answered the question very well, but given the interest in the topic, Jess and I would recommend that Dan S. or Tom approve all replies before they are sent. Also, we should keep a file of these inquiries and our replies.

Thanks!

Ex. 5 Deliberative Process (DP)

From: Audrey Ford <audreytford@gmail.com>
Sent: Monday, November 23, 2020 8:21 PM
To: Walsh, Jonathan <Walsh.Jonathan@epa.gov>
Subject: Request for additional information

To: Jonathan P. Walsh, walsh.jonathan@epa.gov

Good Evening Mr. Walsh,
On October 20, 2020, EPA published a notice in the Federal Register regarding EPA's "Approval of the Request for Other Use of Phosphogypsum by the Fertilizer Institute". One of the technical documents supporting this approval, posted on

EPA's webpage dedicated to this issue, is titled "Technical Review of The Fertilizer Institute Risk Assessment for Additional Use of Phosphogypsum in Road Base," dated June 10, 2020. Multiple times in this review document, it is suggested that The Fertilizer Institute (TFI) provide further information and/or analysis on specific issues. For example, on page 46, it is recommended that TFI be required to further explore both the groundwater and ingestion of crayfish exposure pathways; on page 45, it is recommended that TFI be requested to revise its reclaimer radon exposure dose calculations, and it is stated that "TFI's evaluation of the Nearest Resident exposure pathways needs to be revised." I am wondering if EPA ever requested these revisions, if TFI ever provided them, and if so, where I might access documentation of those revisions? I have explored all the links included on the EPA's "Approval of Other Uses of Phosphogypsum: Supporting Documents" web page and have been unsuccessful in identifying any such document. Thank you in advance for your time and consideration.

Respectfully,
Audrey Ford

Hi,

Sorry, I forgot the other two attachments that I note in my comments. These are not intended to be all encompassing treatments of their subjects, but they provide you with some illustration of what I'm saying.

Hi Jess and Stefanie,

Thank you, and the whole team for this comprehensive plan with questions/answers, website information, etc. It looks very good.
I have comments for you in this attached document. I'd like to see the next iteration please.

Subject: TFI Communications Plan

Good afternoon Lee,

Below is a SharePoint link to the Fertilizer Institute Communications Plan. This document heavily relied on input from the technical team, and has been reviewed by Jessica, Dan, and Tom. Prior to sending it to you, I addressed most of the comments from earlier reviews, including track changes suggested by previous reviewers. You will notice though, that there are a small number of comments, placeholders, and reminders that I will need to address before the document is final.

Link to SharePoint:

Ex. 5 Deliberative Process (DP)

The next step in the review process would be for Jon and Andrea to review the package. Please let me know if and when you would like me to assist with shepherding the document to them. I would also understand if you wanted to pass it on directly.

Finally, and as always, please let me know if you have any questions.

Thank you,
Stefanie

PHOSPHOGYPSUM: SHOULD WE JUST LET IT GO TO WASTE? PART 1

MONDAY, MARCH 15, 2004

House of Representatives,
Subcommittee on Technology, Information Policy,
Intergovernmental Relations and the Census,
Committee on Government Reform,
Bartow, FL.

The subcommittee met, pursuant to notice, at 9:33 a.m., in the West Wing, Southwest Florida Water Management District Headquarters, 170 Century Drive, Bartow, FL, Hon. Adam H. Putnam (chairman of the subcommittee) presiding.

Present: Representative Putnam.

Staff present: Bob Dix, staff director; John Hambel, senior counsel; Ursula Wojciechowski, professional staff member; Juliana French, clerk; and Matthew Joyner, district director.

Mr. Putnam. A quorum being present, this hearing of the Subcommittee on Technology, Information Policy, Intergovernmental Relations and the Census will come to order.

Good morning, and welcome everyone to the subcommittee's first hearing on phosphogypsum. Today's hearing is appropriately entitled, ``Phosphogypsum: Should We Just Let It Go To Waste?''

I want to thank the community for their interest in this issue. As indicated by the wonderful turnout that we have today, this is an issue that is very important, not just to Polk County but to all of central Florida and even beyond that.

Currently there are about 1 billion tons of phosphogypsum stored in 24 stacks in Florida, 21 of those stacks here in central Florida. Thirty million new tons of phosphogypsum are produced every year, and we meet today in the shadows of one of those stacks, one of these gyp stacks, as the locals call them, here in the Southwest Florida Water Management District building.

Phosphogypsum is a byproduct of the chemical processing of phosphate rock mined here in Florida. In 1989, the U.S. Environmental Protection Agency promulgated a rule determining that the commercial product of phosphogypsum was a waste product and banned its use for any purpose whatsoever. From

ED_005285_00000595-00003

that point on, the phosphogypsum has been accumulating all over the State.

The possibility of a catastrophic spill in Manatee County last year raised local and Federal concerns. In 2001 the Mulberry Corp., the owner of the Piney Point Phosphates went bankrupt leaving a plant with unattended stacks of phosphogypsum. Since then, the State of Florida has kept the electricity going at the plant and monitored water levels in the phosphogypsum stacks. Last year, the Florida Department of Environmental Protection was granted Federal permission to discharge more than 500 million gallons of treated wastewater from the Piney Point Plant into Bishop's Harbor in Tampa Bay. EPA and the Department of Environmental Protection insisted that it would not be harmful to marine life and others contended that the solution, while the lesser of two evils, would be less environmentally damaging and more economically sound than a spill. That discharge was estimated to span 19,500 square miles and cost $10 million. Although that cost will be covered by a trust fund that phosphate companies pay for environmental restoration, Florida State government has spent $40 million so far to maintain Mulberry's abandoned plants at Piney Point and in Polk County. The expected maintenance and closing costs will total $170 million which will fully deplete the trust fund.

Scientific research conducted and the results found by various entities support a position that phosphogypsum is not a waste but a potentially valuable commercial product. Conclusive evidence by independent researchers and research councils challenge the claims that use of the product is harmful and suggests that specific applications be reviewed. It can be environmentally safe and economically attractive to use phosphogypsum in a variety of ways serving industry and potentially benefiting the taxpayer. Considering that the environmental dangers of stacking phosphogypsum to the unlikely risks associated with the use of it outweigh the risks of storing it as a waste product. We will examine this question and the environmentally safe, potential uses for phosphogypsum this morning.

This morning's hearing will immediately be followed by our second hearing that will focus on understanding the purported risks of phosphogypsum as determined by the Environmental Protection Agency. Representatives from Florida's State and local government will share their thoughts on the risks and uses of phosphogypsum. And finally we will hear the concerns of a dedicated environmentalist involved with the Tampa Bay estuary program.

Ordinarily I would yield to the ranking member of the subcommittee, Mr. Clay from Missouri, for any opening remarks; however, given that this is a field hearing and not in Washington, we will immediately proceed to witnesses for their testimony.

As is the custom for the Government Reform Committee, we swear in our witnesses, so I would ask the first four panelists and anyone joining you who will provide supporting information to our questions to please rise and raise your right hands.

[Witnesses sworn.]

Mr. Putnam. I note for the record that all the witnesses respond in the affirmative.

We will proceed to our first witness, Mr. Michael Lloyd. Mr. Lloyd is the research director of chemical processing at the Florida Institute of Phosphate Research. He received his chemical engineering degree in 1950 from Clemson University. After graduation he worked in the Chemical Corp. for the U.S. Army and Southern Cotton Oil Co. Before joining the Florida Institute of Phosphate Research in 1982 Mr. Lloyd worked 30

ED_005285_00000595-00004

years for Agrico Chemical Co. serving many roles from foreman to project coordinator and director. He participates in the American Institute of Chemical Engineers and the American Chemical Society. Mr. Lloyd is quite possibly the only person to have direct contact with almost all of the events related to phosphogypsum and the EPA since the Florida Institute of Phosphate Research was formed in 1979. His extensive research on the subject of phosphogypsum is commendable and we look forward to his expert testimony. Welcome to the subcommittee, Mr. Lloyd, and you are recognized.

[The prepared statement of Hon. Adam H. Putnam follows:]

[GRAPHIC] [TIFF OMITTED] T5739.001

[GRAPHIC] [TIFF OMITTED] T5739.002

STATEMENTS OF G. MICHAEL LLOYD, JR., RESEARCH DIRECTOR, CHEMICAL PROCESSING, FLORIDA INSTITUTE OF PHOSPHATE RESEARCH; DR. MALCOLM E. SUMNER, AGRICULTURAL AND ENVIRONMENTAL CONSULTANT, REGENTS' PROFESSOR EMERITUS, UNIVERSITY OF GEORGIA; DR. DOUG CHAMBERS, EXECUTIVE VICE PRESIDENT, DIRECTOR OF RADIOACTIVITY AND RISK STUDIES, SENES CONSULTANTS LIMITED; AND DR. CHIH-SHIN SHIEH, ENVIRONMENTAL CONSULTANT, CS ENVIRONMENTAL SOLUTIONS

Mr. Lloyd. Thank you.

Finding environmentally sound ways to utilize phosphogypsum was an original priority with the Florida Institute of Phosphate Research. One of our first activities was to have an international symposium on phosphogypsum in November 1980. Our efforts looked at three different basic approaches. To use it as a chemical raw material, use it in construction and for agriculture. We did sponsor research to recover the sulfur values but economics made that somewhat impractical. For construction purposes the only thing we really looked at was to use it for road building. Our plan was to build a secondary road first, test it environmentally and for construction purposes and then go ahead and build a primary and later on an interstate type road.

We did build 2 secondary roads, one in Polk County and one up in north Florida in Columbia County. We have tested both of them environmentally and testing continues on the Polk County road even until today. Testing by the Florida Department of Transportation has revealed that the Polk County road has gotten stronger with time rather than getting weaker. It also has shown fewer repairs than what is necessary for other roads.

Phosphogypsum has been tested for all kinds of agriculture. We have used it for truck crops, for grass, and we have also tested for radionuclide uptake by both the cattle and by the grass. We have used it to find out about curing subsurface acidity and we have also used it to improve the water penetration in the soil. One of the other uses we have gotten into is for marine applications, for making glass and for daily cover in municipal solid waste landfills.

Until December 1989, phosphogypsum was sold as a product of commerce in all States of the country. At that time, EPA elected to declare it a waste and forbid its use, including forbidding research. In the time period between 1989 and 1992, EPA developed the risk assessments that are used as the basis for the use ban in the 1992 rule. The 1989 proposed rule did not have any data to support the ban. All of the bans that they have done are based on building a house on either the roadbed or building it on land that was fertilized with phosphogypsum for 100 years. A residency value of 70 years was used to calculate the risk, which is somewhat longer than the values

ED_005285_00000595-00005

used in many EPA risk calculations.

The ban on agriculture was based on averaging the use in California for soil treatment and using it for agriculture in this part of the country. The two uses that were used to get an average are totally unrelated. They are like saying apples and oranges are the same because both of them are fruits. The 1992 rule did allow the use of north Florida phosphogypsum in agriculture and prohibits all other uses. However, you can use EPA's methodology and prove that building roads, using it in a landfill or anything else will not produce a risk that would exceed EPA's acceptable risk.

The question may be asked why are we so interested in using phosphogypsum. We do believe that leaving it in the stacks is a worse situation than using it. The road building economics are very attractive. The roads we built in Polk County, we saved $100,000 a mile by using phosphogypsum over traditional material. The actual soil use--using it for agriculture in Florida could have an even greater impact. All of the southeast is short on sulfur. Using our phosphogypsum, we would be able to increase the production and definitely affect what cattle raisers do in Florida.

One of the things we would like to continue at this point is using it in landfills. We have demonstrated in both pilot and in the bench scale tests that it would be possible to speed up the decomposition of the material in solid waste landfills. If we can do this we would be able to decrease the amount of landfills that would be needed by 50 percent.

We believe that all of these uses are practical, that the risks are acceptable and we would like to see something happen.

Mr. Putnam. Thank you very much, Mr. Lloyd.

[The prepared statement of Mr. Lloyd follows:]

[GRAPHIC] [TIFF OMITTED] T5739.007

[GRAPHIC] [TIFF OMITTED] T5739.008

Mr. Putnam. Our next witness is Dr. Malcolm Sumner. Dr. Sumner is an agricultural and environmental consultant. Currently he is Regents' professor emeritus at the University of Georgia. He graduated first in his class with a BS in agriculture and cum laude with his masters of science in Agriculture from the University of Natal in South Africa. Additionally, he has a doctorate of philosophy from the University of Oxford. He has edited five books, including the Handbook of Soil Science; authored and co-authored two books; 249 referred papers; 41 book chapters and over 300 publications. Dr. Sumner's specialties include soil contamination and pollution, beneficial reuse of anthropogenic, solid and liquid wastes in agriculture and gypsum as an ameliorant for subsoil limitation, among many other topics. He has extensive experience in international soil science and agronomic research, consulting and teaching. He has received numerous awards recognizing his scientific contributions, including an honorary doctor of science degree from the University of Natal in 1997.

Aside from the fact that you are a Bulldog, you are a very well qualified individual for this panel. Welcome, Dr. Sumner,

you are recognized.

Mr. Sumner. Thank you, Mr. Chairman. Today I am going to talk about the agricultural uses of phosphogypsum. This should be judged against the EPA rule which came up with a value of 2,700 pounds per acre every 2 years for 100 years. This comes down to 1,350 pounds of gypsum per acre per year. So that is the yardstick against which we should judge.

Now gypsum is used in many facets of agriculture, for sodic soils which do not occur in the southeast here, so I will not dwell on those at all. But as a calcium and sulphur source for crops, very important, as an ameliorant for the subsoil acidity and as a physical ameliorant.

I am going to deal specifically, Mr. Chairman, with the rates recommended by our Cooperative Extension Service, which is the imprimatur of the State and Federal Government. For peanuts, in terms of calcium requirements, gypsum is used to strengthen the cell walls of the peanuts to prevent them from getting diseased. The recommended rates vary from 250 to 1,720 pounds per acre every 2 to 3 years. So you are going to divide those numbers by two or three depending on the rotation. That gives you a maximum recommended value of about 600 pounds per acre and a most likely rate of between 125 and 430 with a minimum rate of between zero and 83.

For tomatoes, the gypsum is used to extend shelf life. The recommended rates are between 430 and 860 pounds per acre every 2 years. You have to divide those numbers by two, giving you a maximum rate of somewhere in the region of 430 pounds, most likely rates somewhere between 200 and 300 pounds and a minimum rate of between zero and 143 pounds.

As far as sulphur requirements of the crops are concerned, these are much lower than the calcium requirements, and the recommended values are between 54 and 161 pounds per acre, giving you a maximum of 161 and a minimum of zero.

As far as subsoil acidity amelioration is concerned, the recommended rates vary between 2.2 and 4.4 tons per acre every 10, that was in my report, but my work has continued and that can be now said to be every 15 years. So that gives the maximum rate at 800 pounds or for 15 years at 530 pounds per acre per year, and a minimum rate there would be zero.

To complete the picture, for sodic soils--which do not occur in this part of the world but occur in the western States--the recommended rates for gypsum would be between 7 and 35 tons per acre over the period of the reclamation which one can assume only once is 100 years, and that gives you a maximum rate of 700 pounds per acre per year and minimum rates of between zero and 200.

As far as soil crusting is concerned, the other physical ameliorant use, the recommended rate is between 0.5 and 1 ton per acre every 5 years giving you a maximum rate of 400 and a minimum rate of zero per year application.

For ameliorating subsoil hard pans there is no recommendation, but the rates that are being used are the regional 4.4 tons per acre every 10 years giving you a maximum again of 800 and a minimum of zero.

Now as far as the radiation hazard of the phosphogypsum is concerned, our experiments show that at the rate that we used, 4.45 tons per acre in one application, we found no significant increase in lead-214, bismuth-214 or radium-226 in the soil profile down to a depth of 3 feet over 5 years. There were no increases in radiation in the above-ground parts of the plants. In the sandy soil we found there was a light movement of radium-226 in a column study in the lab, but this level in the leachate was well below the drinking water standard.

So overall, from the rates I have shown you, the maximum rates that are actually likely to be applied in agriculture,

ED_005285_00000595-00007

this 1,350 pound per acre per year proposed by the EPA is too high. A more reasonable level in my view would be between 600 and 800 as the maximum, but the most likely rate, Mr. Chairman, would be between 100 and 400 pounds per acre per year.

The last point I would like to make, the basis of using concentration as the yardstick in banning the phosphate should be revised because I think cumulative load is much more important. Thank you, Mr. Chairman.

[The prepared statement of Mr. Sumner follows:]

[GRAPHIC] [TIFF OMITTED] T5739.052

Mr. Putnam. Thank you very much, Dr. Sumner.

Our next witness is Dr. Doug Chambers. Dr. Chambers is the executive vice president and director of radioactivity and risk studies at SENES Consultants Limited which he co-founded in 1980. He has been working in the area of environmental radioactivity and risk assessment for more than 30 years and has studied both radioactive and non-radioactive substances. Dr. Chambers has worked on projects across Canada, throughout the United States and abroad. He has participated on the United Nations Scientific Committee on the effect of atomic radiation since 1998 as a member of the Canadian delegation. Dr. Chambers is currently a consultant to UNSCEAR with responsibility for preparing the next UNSCEAR assessment of radon. He has supervised and carried out numerous studies of naturally occurring radioactive material in a wide variety of industries, including studies for the Florida Institute of Phosphate Research to examine alternative potential radiological risks arising from alternate uses of phosphogypsum in agriculture, road construction and daily cover at municipal landfills.

Welcome to the subcommittee, Dr. Chambers. You are recognized.

Mr. Chambers. Thank you very much.

As noted by Mr. Lloyd, the 1989 NESHAPS in effect converted phosphogypsum from a useful byproduct to a waste and the focus of the concern here was the radioactivity in the phosphogypsum, which is the same as the radioactivity in the phosphate rock and is naturally occurring.

In 1992 EPA did a reconsideration which allowed alternative uses with prior EPA approval. To my knowledge, I am not aware of any such uses having been approved to date. The EPA commented that the risk from indoor radon and direct gamma radiation were the issues of major concern at that time.

In their 1992 rule in deciding on the maximum acceptable level of radium-226 which they determined to be 10 picocuries per gram, the Environmental Protection Agency used a lifetime risk of 3 in 10,000. I will come back to that in a moment. It is interesting to note that in addition to the 1992 rule, the EPA has used the same lifetime risk of 3 in 10,000 to establish cleanup levels for unrestricted use in CERCLA Superfund sites which have been contaminated with radioactivity. This rule, I believe, specifically excludes the risk from radon in that

factor.

Another important consideration in looking at the EPA's 1992 rule is the rate of which phosphogypsum is assumed to be applied. I cannot compete with Dr. Sumner in that regard. I think I will basically compress my comment to the following: If you use a reasonable maximum application of perhaps 900 pounds then following no other changes in EPA's 1992 risk assessment you could then have unrestricted use of phosphogypsum containing up to 40 picocuries per gram by that simple change in the application rate to something that is more appropriate as opposed to an application rate of 2,700 pounds.

In their 1992 analysis, the EPA assumed a lifetime of 70 years of exposure, and yes, that is indeed possible but it is highly unlikely. In their Exposure Factors Handbook, a document prepared by EPA based on national data and surveys, EPA for other risk assessments recommends a duration of exposure of 30 years, which according to the EPA is the upper 95th percentile. In other words, only 5 people out of 100 might live longer in a single home than 30 years.

It is also interesting to note in their 1999 assessment of the risk from nonradioactive contaminants contained in agricultural fertilizers, the EPA used the average residency of a farmer of 17 to 18 years, also taken from their Exposure Factor Handbook. There is an inconsistency in this regard. I do not have time to go into the details but there is much more in my written presentation.

I would briefly like to comment on risk assessments we have done in support of FIPR's application for road construction, land use, agricultural application of phosphogypsum, daily soil cover for landfill. To comment that when you use distributions of parameters to take account of natural variability and uncertainty the numbers are very different. And we calculate using numbers that are generally traceable and would be consistent with many of EPA's risk assessments, upper risks that are below 1 in 10,000, well within the EPA's risk range from 1 to 3 in 10,000. I think this is very important. These numbers that we calculate would be for a person who lives in a home built on either a road that had been constructed with phosphogypsum or on land to which phosphogypsum had been applied for 100 years. We believe the maximum risk would be less than 1 in 10,000, much less even than the 3 in 10,000 risk limit that EPA has used. I believe it would be unfortunate to preclude beneficial and safe uses of phosphogypsum by unnecessarily conservative risk assessments.

Thank you very much.

[GRAPHIC] [TIFF OMITTED] T5739.026

[GRAPHIC] [TIFF OMITTED] T5739.027

Mr. Putnam. Thank you very much, Dr. Chambers.

Our next witness is Dr. Chih-Shin Shieh. Dr. Shieh is an environmental consultant at the CS Environmental Solutions that he founded in Melbourne, FL. Dr. Shieh was research faculty and the director of the Research Center for Waste Utilization when he conducted the phosphogypsum studies at the Florida Institute of Technology. Dr. Shieh's areas of expertise include waste characterization, minimization and utilization. His academic training, research experiences and professional services have allowed him to become one of the few scientists in the Nation who are able to deal with problems concerning pollution that occur in both terrestrial and marine systems. Dr. Shieh has published more than 40 scientific papers and technical reports in the area of waste stabilization and utilization. He has graduated more than 14 MS and four PhD students under his tutelage. Welcome to the subcommittee, Dr. Shieh.

Dr. Shieh. About 10 years ago when I stood on the top of one of the 300-feet phosphogypsum stack piles, one idea that comes to my mind was what can we do about it. I mean, can we come up with a better approach to manage this material? And just like Mr. Chairman's opening statement, is phosphogypsum a waste or a resource? Now by definition, a waste is a substance that we do not want to use and has no usefulness at all. If the substance can be used for any beneficial purpose and in the meantime does not generate adverse effect to the environment then the material should not be considered as a waste.

So based on that concept we come up with an idea. We can apply phosphogypsum in municipal waste landfills. There is good evidence to suggest that the addition of phosphogypsum could enhance biodegradation of municipal waste in landfills, because during the early stage of waste decomposition in landfills the degradation process is essentially aerobic. That means it depends on the oxygen available so the microorganisms can carry out the process of biodegradation. However, very soon over time as oxygen is depleted the decomposition process becomes anaerobic. That means the bacteria used--you know, some oxygen compounds result dealing with free oxygen in the air. In an anaerobic process--again, that is in an oxygen depleted environment--bacteria depends on oxygen bound in the compound to carry out biodegradation. If there were limited oxygen bound compounds then the biodegradation process will be significantly minimized. So that is why it has been reported that buried bacteria--I am sorry, vegetables such as lettuce--a piece of lettuce was still in good shape after being buried at a site for more than 20 years, because the biodegradation was limited.

ED_005285_00000595-00010

Since phosphogypsum is enriched with sulphate it is reasonable to assume that sulphate using bacteria colonies present in landfills will use phosphogypsum as an energy source after oxygen is depleted. The sulphur enriched phosphogypsum can be used in anaerobic conditions such as landfills.

About 10 years ago, in 1996, we carried out a three-phase study. Phase I took about 2 years, from 1996 to 1998--I am sorry, 1994 to 1996. The phase II started from 1997 to 1999 and three questions were addressed. First, does this concept work? Is this only a hypothesis or is this practical issues? Secondary, we want to know under what conditions this concept could work. And third, we want to answer if this process would generate any adverse effect to the environment.

So in the phase I studies we concluded that yes, this concept is practical. Under experimental conditions phosphogypsum can actually be used by the bacteria and generation of a diverted level of hydrogen sulfate was not found. Also phase I study concluded that if we put one portion--one part of phosphogypsum with three parts of municipal waste together, the reaction would meet our purpose.

So following phase I, we carry out phase II right away. Similarly phase II is to kind of extend the reaction period and use a simulant of municipal solid waste, and we come up with similar conclusions that one portion of phosphogypsum can be used with municipal solid waste and can achieve more than 50 percent reduction in organic matters in 3 months.

So then immediately after the phase II study, we proposed to carry out a phase III field study. That was in 1999. That was about 5 years ago, and it is still pending EPA's approval. Through the field study we will come up with very conclusive findings to demonstrate that this approach is an environmentally sound approach and a lot of parameters will be monitored in the phase III study to further assure there is no adverse effect to the environment.

Thank you.

Mr. Putnam. Thank you very much.

I want to thank all of our panel one witnesses. You know, for those who are trying to digest everything that these engineers and scientists have put before us, what I've heard is that you have through research identified essentially three key potential uses for phosphogypsum--road construction, soil amendment for agricultural purposes and the potential for cover fill on municipal solid waste landfills. And that there has been a great degree of inconsistency, almost a double standard or a rule unto itself promulgated by EPA that applies to phosphogypsum but does not apply to their risk models for other types of products that they are running risk assessment models on. So if we could, let us kind of start at 40,000 feet and work our way down.

ED_005285_00000595-00011

What--to any or all of you--do you believe that the risks associated with dispersing phosphogypsum either through landfill, road construction or agricultural purposes, do you believe that the risks associated with its dispersal, outweigh the risks of stacking it in a concentrated form in the types of mountains that we see? Which risk is greater, concentrating it or dispersing it? We will begin with Mr. Lloyd.

Mr. Lloyd. No, I definitely do not think that the risk of using it is as great as leaving it in the stacks. I think you are going to have some long term effects that you will have to deal with. My concern with using it is basically not very large. One thing that I would tell you is, if we built a road with it, I would have no argument about my children or my grandchildren or myself living alongside the road, and I would not have any concern about living in a house 100 years from now, which I will not get a chance to do, that had been fertilized with phosphogypsum. I think the work that Dr. Chambers has done demonstrates this very, very strongly in a scientific basis.

Mr. Putnam. Dr. Sumner.

Mr. Sumner. Mr. Chairman, I cannot speak for the risk of the stack because that is out in my backyard. I do not know much about that, but I can tell you pretty well categorically that if you use phosphogypsum at the recommended rates according to the Cooperative Extension Service, there is absolutely no risk because we were able to find no radiation residue as a result of applying phosphogypsum in all the agricultural applications that we have made. In fact, if one is concerned about the radon gas, in many parts--not so much in Florida, but in much of the Piedmont part of the Southeast, the radon emanating in basements is probably a bigger threat than anything you would ever get from phosphogypsum. So I think the risks are absolutely minimal when used correctly. Now, of course, if you use it incorrectly that is another matter, but that is off-label so to speak and one cannot address that in a hearing like this.

Mr. Putnam. Dr. Chambers.

Mr. Chambers. Thank you. I would like to make two comments. First of all, I agree with Mr. Lloyd that the use of phosphogypsum for agriculture, for roads, for daily cover on a landfill, and there are some other uses we did not have a chance to talk about today as well, would indeed in my opinion actually be smaller risks than the risk associated with leaving the phosphogypsum in the stack.

The referenced scenario here is building a home. So if you were in the future to lose control of the land--and that is a whole other issue--and build a home on a phosphogypsum stack the radium-226 concentration, which is really the issue we are talking about, would in fact be simply the radium-226 concentration in the phosphogypsum per se. For any of the uses we are talking about with appropriate land application with dilution in the daily cover, the actual final concentration of radium-226 would in fact be smaller than it was in the undiluted phosphogypsum, and indeed so small that it would be difficult to find within the natural variability of radium-226 which occurs in my backyard and your backyard and everybody's backyard. And indeed the radon flux that would arise from the incremental radium-226 because of the phosphogypsum would in my opinion be so small that it would not be detectable within the natural variation of radon that occurs in homes in Florida and indeed throughout the United States at the present time. Setting aside the absolute risk, which I personally believe to be extremely small, the incremental risks compared to radium and radon from natural background would be vanishingly small and in my opinion not measurable. Thank you.

Mr. Putnam. Dr. Shieh.

Mr. Shieh. If the use of phosphogypsum is under good monitoring, I do not think that kind of use will be worse than current practice.

One comment about the future of building on the site, the possibility in terms of risk assessment. For some reason that concept has been used everywhere in the whole country. When I was involved in Zinereta Ash project a similar question was always asked, how about 100 years later if my grandchildren build a house on the abandoned site with all kinds of waste material? We need to be honest and understood that today we already have very good systems, OK. One of the provision of service I am doing now is when the builder or the developer, they try to develop a site for new business, community or new residential community, they are required to do so-called phase I site assessment studies. And through that study any location--any property will be investigated for the history of the property. So practically and realistically that scenario will not happen even 100 years later unless the whole governmental system was destroyed for some reason, otherwise that is really not a scenario that would happen, that someone would build a house on the top of a waste pile. It is not going to happen. Again, we have very good system today already. So I truly believe if any good use of the material and under monitoring, then I support that idea.

Mr. Putnam. You know, the only way to deal with these issues is in a straight-forward science-based manner and you have certainly given us a foundation for a science-based approach to alternative uses of phosphogypsum. But, you know, radioactivity, that term certainly conjures up concerns, fear even among people. Help the subcommittee to understand the context of the radium-226 levels. How does it relate to other commonplace daily activities that people may be engaged in and whatever the background radiation of those may be, whether it is flying or smoking or the presence of radon in homes today? Help us put that number in context.

Mr. Chambers. Perhaps I will try. First of all, I would like to try and provide a small context on the risk range of 1 times 10 to the minus 4. As I mentioned--that is 1 in 10,000--as I mentioned earlier, the EPA has also used risk numbers as high as 3 times 10 to the minus 4 in rulemakings and therefore at least for that purpose, EPA, one would presume, considers that level of risk as safe. Well what is a risk of 1 in 10,000? That is a lifetime risk. So if you use EPA's notion of a lifetime of 70 or 75 years, in essence that works out to an annual risk of about one in a million. I am not going to tell you my exact age, but I am somewhere between 50 and 60 and it is pretty typical unfortunately that at my age natural causes of death in the average person, I would have a risk of about one in a million from just 1 hour of doing what I do every day. So assuming this hearing this morning takes 2 hours, my risk would be approximately two in a million just from just simply sitting in this room and enjoying this conversation. That's the kind of context we are looking at. It is a risk I suffer every hour or am exposed to every hour of the day at my age. It is unavoidable.

Radioactivity is unavoidable. All soils everywhere have naturally occurring radioactivity and in particular radium-226, which is the focus really of this discussion because it is a source of the radon that crops up in the open air and comes through our floors into our homes.

In any event, if you look at--it does not matter whether you look at EPA's risk assessments or ours, the incremental contributions of radium, even after 100 years of application, that I think this panel would consider exceptionally high

application rates, is still well within the range of natural radium-226 in soils. So you are not going to be changing that. And if you look at--GEOMET did a very detailed study of radium in soils and indoor radon in homes in this county and in many other counties in Florida. And if you look at the maximum incremental radon contribution it is less than a tenth of the average and less than a thirtieth of the upper number. It is a very small fraction, much less than the variation you would go from one home to the next because of the difference in life styles, slightly different age of construction. It is not a detectable phenomenon. I am a physicist, I like models, it is something I can predict. It is something EPA can predict, but I believe it is not something you could actually measure because it is there naturally in much higher and very variable quantities.

Finally I might add, the EPA has a 4 picocurie per liter standard at which they would like to have people initiate cleanup in the homes and what we are talking about, the maximum incremental contribution that I would predict would be more than 20 times smaller than that. The absolute maximum much less the average.

I hope that provides some context. Thank you.

Mr. Putnam. Does anyone else wish to add anything to that? Mr. Lloyd.

Mr. Lloyd. I always find it kind of comical that since you are in a granite office building in Washington, you probably have more radon than what most of the people in this room experience in a day.

Mr. Putnam. EPA has a nice big granite building, too, maybe that is what is going on there. [Laughter.]

The roads that were constructed in Polk County, there are homes along that road, Mr. Lloyd. Do you know how many homes are along that road?

Mr. Lloyd. May I ask a question?

Mr. Putnam. You may.

Mr. Lloyd. John, how many homes?

Voice. About 40.

Mr. Lloyd. About 40.

Mr. Putnam. Forty homes along the road that had phosphogypsum used as the road base. Does testing continue along that road?

Mr. Lloyd. Testing is continuing on it even until today.

Mr. Putnam. And you mentioned that the DOT testing indicated that roadbed has grown stronger over time, which is certainly a favorable thing for its durability as a roadbed, but what are the health effects that have been detected as part of that testing?

Mr. Lloyd. The road is kind of difficult to come up with the health effect for one reason. Everything we have shown is fairly normal. The land the road is built on is reclaimed land. The radiation over the land next to the road is higher than the radiation on the road. So the people that are living there are experiencing radiation levels that are higher than they would ever have if they built the house on top of the road.

Mr. Putnam. OK. What other leachates have been found in the monitoring of the roads already built in Polk County?

Mr. Lloyd. The only thing that we may have seen--and I will ask Dr. Burkee to correct me if I am wrong--is the sulphate increase at one well.

Mr. Putnam. You mentioned that NASA and the Department of Energy have expressed an interest in using phosphogypsum based glass in a ceramic material. Could you elaborate on that?

Mr. Lloyd. Well we have a proposal to make glass out of phosphogypsum. We have done all the research. We are trying to--the people that did the research are trying to put together

a system to start making glass. One of the techniques that has been studied would actually--in preparing the phosphogypsum for use, would enable you to produce hydrogen. In the course of our discussions--and this is still a preliminary study at this point, a paper study more than anything else. But in talking to both NASA and DOE, they are very interested in the fact that you might be able to produce hydrogen. NASA because they use it for launching space vessels and DOE because they would like to see us go this hydrogen-based economy that has been proposed that would reduce greenhouse gases. We are interested and we are working. That is all I know to say at the moment.

Mr. Putnam. All right, sir. Dr. Chambers.

Mr. Chambers. I have one further comment. I did not have the chance in my comments this morning to say anything about the glass. I would like to point out that when you make the glass you do not do anything obviously to change the gamma radiation, but, in fact, you trap the radon. The radon cannot escape. So in essence because it is like wall tiles--it is like a ceramic like material--the radon which has a half life of 3.8 days will decay within the glass like material and actually not be available to enter the rooms of living spaces or working spaces. So in actual fact, the radon risk in that case would be very much lower.

Mr. Putnam. Could you elaborate on the half life of 3.8 days? Was that what you said?

Mr. Chambers. Yes, I will. Radon-222 is a noble gas so it is able to diffuse through air and through soils, but it does have a radioactive half life. If you take 120 atoms of radon now in 3.82 days you will have approximately, plus or minus, 60 and in 7.6 days if my arithmetic is correct, you will have half of that again. So you will have 30. In another 3.8 days you will have 15. That is about as far as my mental math can carry me.

But in essence the radon that is produced within the matrix of a soil, within a matrix of PG, within a matrix of a cemented road can only survive because of its physical half life for a finite time and the average time is 3.8 days. Therefore, if something interferes with how easy it is to diffuse through the pore space well then it will decay and never actually enter the open air or the air of a building in which you might use tiles for a roof or a floor. So in actual fact, as I say, it does not do anything to change the gamma levels which is another kind of radioactivity. But certainly making it into a glass-like material hugely reduces the fraction of radon that can survive long enough to actually be released into room air. Thank you.

Mr. Putnam. Thank you.

The EPA risk model for phosphogypsum was a 70-year residency for occupants of a hypothetical house. When calculating the risk for phosphogypsum that is 18 hours a day, 7 days a week for 70 years. Does that assume an airtight house, air conditioning, no air conditioning, ventilation, windows open? How does that factor into that risk assessment?

Mr. Chambers. If I understand the EPA's risk analysis correctly, I do not think they actually considered any of that. I think they used--I stand to be corrected, but I believe they used a generic factor whereby they took the radium concentration in the soil that will be built up over time by application of this very high fertilizer rate, for example, and then use a factor--for every picocurie per gram of radium-226 in the soil you would find 1.25 picocuries per liter in the indoor air of the home. So it is a generic--it is a generic number.

Mr. Putnam. And what is a more reasonable risk analysis number to use other than the 70-year residency?

Mr. Chambers. I have some sympathy for EPA nationally, but

when you look at--for example, in Florida there is a huge amount of data that relates--from the GEOMET survey, for example, that relates specifically to soil concentrations of radium and the corresponding indoor radon levels. So one of the things that we did in our risk assessment for uses in Florida was to try and use as much Florida-specific data as possible. I think it is important where information exists to use data that is appropriate for the application and appropriate for the intended area of use.

Mr. Putnam. Mr. Lloyd, have you received approval from EPA to pursue NASA's request to utilize phosphogypsum in glass?

Mr. Lloyd. We have not really talked to EPA about the glass. That will be the next thing when we decide to go into a full scale plan. We have done all the benchwork, we have done all the pilot work. We would like to go into a demonstration sized plant and that is in the works. We will need to go to EPA at that time. Based on our past experience with them, it will take 3 or 4 years to get an answer.

Mr. Putnam. Do you have any permit requests pending with them now?

Mr. Lloyd. We have one with them for the landfill that Dr. Shieh mentioned. Down in Brevard County they have agreed to let Dr. Shieh build a test cell that would be large enough to demonstrate to landfill operators the effectiveness of this technique. We asked 2 years ago, plus or minus, to get approval to do that. We have had--the problem we experience with most of these things is EPA said in 1992 that they would define the method to get an exemption to the rule. They have never done anything. We have tried to put things together, working particularly with Dr. Chambers for requests that would meet all of the requirements. Our biggest problem is we turn it in and in about 4 months, 6 months or 8 months later we get something that says you need to add this. So we add that, and in another 4, 6 or 8 months we get another request that says you need to add this. So getting anything through EPA in terms of an exemption to the rule is not the simplest thing that anybody ever did. The only thing that we have that would stand up today is, EPA has said that if we wanted to build a road, if we would get a deed restriction on the road so that you could never build a house on it, that they would have no objection to building the road. But even when we have worked with getting an exemption request for a given road, even with a deed restriction, we have to have an exemption request. It has been a long-term, frustrating affair.

Mr. Putnam. Dr. Sumner, you went into great technical detail on the calculations that EPA used particularly for the agricultural uses. Could you take some time to elaborate on the calculations they made versus the calculations that you believe that they should have made using realistic assumptions for the soil types and the crops that are being tested?

Mr. Sumner. Well they came up with this value that was 2,700 pounds per acre every 2 years. That is the standard that they set the rule on. Now, I do not know the exact calculations that they went through establishing the rule. What I am saying is that the uses of gypsum that are recommended by the Cooperative Extension Service are all much below that level. So that should--the actual uses that are recommended in the agricultural industry are the rates that should be used in the calculation, not the value they used. That is my point.

Mr. Putnam. Are the calculations that they used available?

Mr. Sumner. Yes, I think so. Well, I do not know if they are available. I started at the point of 2,700. That is what I know. I do not know about their calculations.

Mr. Putnam. Are the working papers that are used by the EPA, are they available to the public through our traditional

open records laws?

Mr. Lloyd. The working papers for the 2,700 pounds are available in the BID documents for the 1989 rule. What they did was take California's applications for sodic soil, which is, as Dr. Sumner has mentioned, are significantly higher than you would use for fertilization. They took those and averaged them with numbers that were used for fertilization from Georgia and Florida. They did a couple of things wrong when they did this. No. 1, they were not agronomists obviously. They did not look at what Dr. Sumner has mentioned about peanuts in which you apply phosphogypsum 1 year but you do not plant peanuts again for another 2 years. You use a 3-year crop rotation. If you do not do this, you get nematodes that destroy the quantity of peanuts and you get a fungus that will destroy the quality. So they took these two totally dissimilar techniques and used them to average to come up with a 1,350 pound per year average. We should really be dealing, as Dr. Sumner says, probably no more than 400 or 500 pounds per acre. We should not be comparing, as I say, the soil treatment with fertilization. This is like taking apples and oranges and saying they are both the same because they are fruit.

Mr. Putnam. You have made that point that the California numbers are irrelevant to the needs of the Southeast. Could you explain what a sodic soil is and why it is a different animal than the Southeast?

Mr. Sumner. Mr. Chairman, I think I will do that.

Mr. Lloyd. He can do a better job than I can.

Mr. Putnam. Go right ahead.

Mr. Sumner. Sodic soil, Mr. Chairman, is a soil that is impacted negatively by the presence of sodium irons. The sodium irons in the soil cause the physical properties of the soil--in other words, the ability of the soil to accept water at the surface and transmit water through the profile--to be very negatively impacted. So in sodic soil the transport of water from rainfall to some groundwater point is impacted very negatively. It is very slow and they are very difficult soils to work on. The phosphate--well phosphogypsum or any gypsum--generic gypsum is used in the reclamation of these soils and supplied at--relative to what we use in the Southeast here, relatively high rates, in order to exchange the sodium from the exchange complex of the soil and replace it with calcium which improves the physical condition of the soil. So that is a reclamation technique, and you would only do that once. So the rates that they use, sort of 35 tons maximum, would be for a one time application to reclaim the profile so you can bring it back into agriculture. So you should divide that by 100, in my view, by the standards that the EPA has used to assess the annual rate, because you only apply that once in the whole lifetime of the soil. Once you reclaim the soil, it will stay reclaimed provided it would not be inundated by the sea or some other negative introduction of sodium into the soil. So once you reclaim it it is reclaimed. So that is the crux. And, of course, it is not relevant here in the Southeast at all. We do not have any sodic soils that are in agriculture in the Southeast at all.

Mr. Putnam. Now in north Florida the phosphogypsum byproduct of the mining up there is allowed to be used as a soil amendment and it is used predominately by peanut growers. Do you believe that the differences in the north Florida phosphogypsum and the central Florida phosphogypsum are significant enough to allow the use of one and ban the use of the other?

Mr. Sumner. Do I think that?

Mr. Putnam. I will begin with you.

Mr. Sumner. Absolutely no. I mean, as far as I am

concerned, at the rate you would use them as an ameliorant for peanuts, I do not think you would ever be able to find any difference in the peanuts or the soil. I mean, it is far lower than the rates--we actually tested the radiation, it was applied at rates that were of the order of three and four times the rate that would be cumulatively applied to peanuts.

Mr. Putnam. Mr. Lloyd.

Mr. Lloyd. I do not think you would have any problem. EPA based their ruling on the fact that north Florida has 10 picocuries per gram of radium and central Florida has an average of 26, and that is where their differences came from. But I am like Dr. Sumner, I cannot see where you would ever have enough phosphogypsum used in agriculture for fertilization that it would ever cause a problem. We did have some work that was done by Dr. Jack Grexicle with the University of Florida using it on forage. As I have mentioned, in Florida, if we could do what Jack thinks we could, we could improve the quality of the grass to the point that we could make a very definite positive economic effect for the Florida farmer, because a cow uses grass that has the proper level of sulphur more efficiently than it does some other grass. You have demonstrated in parts of the world 20 percent weight gains just because of having proper sulphur fertilization. Jack is here today. If you all would like to have him address you, he can give you all the details.

Mr. Putnam. Dr. Chambers.

Mr. Chambers. Thank you, very much. It is difficult to add to what my colleagues have said, but I would like to make one additional comment. As Mr. Lloyd indicated there is considerable detail about the EPA's risk assessment in the 1992 BID, including the EPA's own analysis of the effects of a biennial, every 2 years, application rate at 900 pounds per acre for 100 years. Without any other changes, even leaving the 70 years, and without any other changes to the risk assessment the EPA themselves indicate the lifetime risk from the application of 900 pounds every 2 years is less than 1 in 10,000, well within their risk range. So even if you--even if you doubled that, that would still be well within the range of 3 in 10,000. So I think simply without any other changes, even by EPA's own risk assessment, with the appropriate application rates there should be no restriction in my opinion at least on the use of phosphogypsum as an agricultural installment.

Mr. Putnam. Dr. Shieh, do you wish to add anything?

Mr. Shieh. No. I did not study on this subject, so I do not want to make comments.

Mr. Putnam. The phosphogypsum from north Florida is allowed by law to be used for agricultural purposes and the phosphogypsum down here is not, and it is not allowed to be used for a roadbed with the exception of the test roads that were built. Now this being Florida, do you not believe, Mr. Lloyd, that the likelihood of building homes on top of previous agricultural land is greater than the likelihood of building a home on a road bed?

Mr. Lloyd. Well, I have always had a problem in understanding why anybody would build a house on a roadbed. [Laughter.]

Particularly in Florida. I do not know how to explain the logic. That is all I am going to say. I would doubt--I just do not know where this ever happens, but I doubt that it is going to happen in Florida.

Mr. Putnam. Well, I do not want to ask our scientists who are very precise to speculate outside their field, but I think that the facts would show that more homes are built in Florida every year on former agricultural acreage than on former road beds.

ED_005285_00000595-00018

Dr. Shieh, you suggest that the bacteria would use the sulphate enriched phosphogypsum after oxygen is depleted and delay anaerobic decomposition. Does that have any beneficial effects on methane reduction in landfill?

Mr. Shieh. Yes. When I say that is typical in an ordinary landfill, carbon dioxide would be generated first when there was oxygen available, so that would be the byproduct of organic decomposition, is generation of carbon dioxide. And over time, when the oxygen has been depleted, the methane begins to degenerate and the carbon dioxide begins to convert to methane. So it is like a curve, from there, to rise and decrease over time and methane from left to right will increase over time. So there is intersection at a certain point. What we discovered is that the intersection between the two extends beyond the time. That is an indication that the production of carbon dioxide has extended, prolonged, as many more organics have been decomposed. And in the meantime, the generation of methane was delayed because as the more organics decomposed slows up the actions.

So that is what I meant in the summary, that by introducing additional available sulfate in phosphogypsum, that would extend and provide opportunity to have more organic matter decomposed and that further would reduce the volume of the waste accumulated at a landfill. And that is why we say we might be able to extend the lifetime of the landfill.

Mr. Putnam. So increasing the efficiency of the decomposition. Has your research given you any indication of how many more years of service a municipality or local government may get out of that landfill if they were able to use phosphogypsum as cover?

Mr. Shieh. Just based on the laboratory results, for example, if we compare the experimental reactor and the control reactor, in 3 months, we actually see more than 50 percent of organic matter has been decomposed on the experiment with phosphogypsum. So we say 50 percent more of the organic matter will be decomposed from the landfill. So we can say that is two times that the time could be extended. So assuming the site, the ordinary landfill, they say is 25 years, so we might be proposing an assumption could extend to 50 years of time. That is one simple assumption. Of course, as I say, if we were able to carry out a phase III field study, then we would be able to come up with more conclusive comments.

Mr. Putnam. And you have a request pending before EPA to your phase III study?

Mr. Shieh. Yes.

Mr. Putnam. And when did you submit that request?

Mr. Shieh. Immediately after completion of phase II, we submit to FIPR and FIPR went through the typical reviewing process, tech committee and the board of directors. They reviewed it and they actually approved the funding but because of the issue on the radioactivity, we have to wait for EPA to make a final green light. That was in either 1999 or 2000, about 4 years ago.

Mr. Putnam. So you have been waiting 4 years for an answer to your request for your phase III.

Mr. Shieh. Yes.

Mr. Putnam. And were there adverse results in phase I or phase II that might have led EPA to delay their decision?

Mr. Shieh. I do not think so. Throughout the phase I and phase II studies, except the issue on radioactivity, which we did not address because that was not a task of the study. On the other hand, we looked at the possible production of hydrogen sulfite, because when we introduce additional sulfur, theoretically we will consider there is going to be more hydrogen sulfite produced at the site, and theoretically that

is possible.

Another possible adverse effect would be the generation of ammonia. Ammonia at the site would prohibit microbiological process. And our study showed that the production of ammonia did not actually stop the microbiological process and the generation of H2S, hydrogen sulfite, was really not on a register label comparing the typical landfill site. And the reason we investigate and the reason could be because of formation of metal sulfite. During the formation of hydrogen sulfite, the sulfur compound could create ways to dissolve metal in the leachate and form the metal sulfite. Under that scenario, the hydrogen sulfite would not be generated.

So we believe throughout the phase I and phase II studies, there is no adverse effect that could make the EPA slow down the process, and personally, I have no idea why they cannot make a decision as quick as possible.

Mr. Putnam. Thank you, we'll have the opportunity to ask that this afternoon.

Dr. Chambers, you have gone into some detail about the 1 in 10,000 versus 3 in 10,000 standard. Are there other examples that you are aware of where they employ a 1 in 10,000 standard instead of their typical 3 in 10,000?

Mr. Chambers. I believe I pointed out another example in my written testimony, which relates to the cleanup of a radioactive contaminated site from the fuel cycle. EPA I believe has a 15 millirem per year dose limit and the NRC, for the same situation, has a 25 millirem, and this has been much discussed. EPA equates a 15 millirem dose to a risk of 3 in 10,000, but it is also very clear that 15 millirems does not include the dose from radon. So in actual fact, if you added radon in, the equivalent risk level would be much higher.

I do believe that in that context, EPA would require a demonstration that you did not exceed their 4 picocurie per liter limit in addition to the 15 millirem.

Mr. Putnam. The 95th percentile application rate--and this is a followup to what we just discussed--is the 1 in 10,000 the 95th percentile, or is 3 in 10,000 the 95th percentile?

Mr. Chambers. The 3 in 10,000 was the upper 95th percentile, which was the 2,700 pounds we referred to previously. As I mentioned though, the EPA's own analysis, using all their parameters in the 1992 BID concluded that an application rate of 900 pounds would produce a risk less than 1 in 10,000. So even if you doubled that to 1,800 pounds a year, that would certainly be less than 2 in 10,000, still within the EPA's risk range of 3 in 10,000.

So I think with the application rates that Dr. Sumner has indicated, that the EPA's own 1992 analysis would demonstrate, even with the conservative assumptions that they have made, that risk to someone building a home on land to which you applied 900 pounds or even twice that, for 100 years, would be well within their acceptable risk range.

Mr. Putnam. We have focused mostly on the road bed, the landfill and the agricultural uses with the additional potential for the glass use. Dr. Shieh, you have done some work on the marine side of things. Are there potentials in that arena as well?

Mr. Shieh. In the marine environment, we actually had some idea in terms of using the material for artificial reef in the ocean. Our organization did not make this proposal. Louisiana State University with a similar group, they actually proposed to do that. Maybe Mr. Lloyd can make a further comment on that.

But yes, based on our previous studies and experience, we agree this material can be used for marine purpose, because the material is good for stabilization, can turn into a solid substance without any question at all. So if the radioactivity

issue can be resolved, I do see it as a good application in the marine environment.

Mr. Putnam. Thank you. Mr. Lloyd, did you want to add anything to that potential use?

Mr. Lloyd. Louisiana State has done a great deal of research on using it in marine applications. They originally proposed using it for oyster conch, which is the solid material on which the young oyster attaches and grows from that point. It used to be you took all the oyster shells and returned them to the ocean and the young oysters could grow on the old oyster shells, but they have become too valuable to be put in the ocean. So now, they do import into Louisiana, granite out of Mexico. One of the problems in much of the Gulf is you put down this material and it is on top of the soil and over a period of time, it sinks down into the soil. So you no longer have a site for oysters.

In addition, they want to use material of this nature to stop the erosion of some of the shores along the Gulf. There is a great deal of erosion into the marshes in fact all along the Gulf in Louisiana.

And a third application that they are working on is for artificial reefs. They have developed formulas that would be economical and compete with material that would come out of Mexico. They have looked at the radionuclide situation to see what would likely happen if they had oysters growing or any other marine creatures growing on this material and they have determined that there is not a significant problem with any of the materials in phosphogypsum going into the food chain.

But they are quite enthused, and in fact, I have a proposal on my desk for some additional work right now from Louisiana State.

Mr. Putnam. That is an interesting segue into what other States are doing. Phosphate is not only mined in the United States either. What are other nations doing with phosphogypsum, what are the permitted uses in some of the other areas that also have phosphate mining? Dr. Sumner, perhaps you could speak to that?

Mr. Sumner. Well, being a native South African, I know the situation in South Africa. The phosphogypsum that is made there is not radioactive, the source of phosphate is a different source and does not contain anywhere near the level of radioactivity that the Florida source does. And the gypsum is freely available and in fact, the excess until recently--they might not have stopped yet, but they are about to stop--was pumped out to sea. So there appears to be no environmental hazards associated with that at all, because it does not contain any radioactivity.

And may I add one----

Mr. Putnam. You may.

Mr. Sumner [continuing]. New potential use, Mr. Chairman. Research has been carried out at the University of Georgia and is still underway, but in a very minor pilot study, we have found that application of gypsum, and it was not phosphogypsum, but generic gypsum, on the top of poultry litter in poultry houses, we can look forward to the possibility that when that litter is applied on land, that the application of gypsum will reduce the level of water soluble phosphorus which is a serious concern for the contamination of surface waters. We have only done this in the lab, pilot study, still going to be extended to the field, but that is another potential source that will be considerable in magnitude throughout the country because of the chicken industry being quite ubiquitous.

Mr. Putnam. Thank you. Dr. Chambers, would you like to speak to the international nature?

Mr. Chambers. Yes, I would. First of all, I would like to

say that the EPA is well-regarded, as it should be, nationally and internationally, and quite often--I was in Brazil last year and Brazilians basically look to EPA for what can be done with phosphogypsum in application there, again, for road construction. So the EPA's determinations are very important and they extend, not just in Florida and throughout the United States, but they have worldwide implications. And that was a road application I was involved in.

In Canada, at the present time, there are a variety of uses being looked at, one of which--and I am not an agronomist, so I apologize here, but I know that a company north of Edmonton is working with feedlots, cattle feedlot users, and the phosphogypsum is being mixed on an experimental basis to reduce odors. And it apparently is extremely successful. That could be a potentially important use.

There have been experimental studies done on using phosphogypsum to reclaim in northern Alberta something called the Tarsands, which is a large mining operation, there has been experimental work with regard to using phosphogypsum to help reclaim Tarsands, a very good, positive, positive thing, and it worked very well on the experimental test.

So there is work underway. I cannot speak to the work that is carrying on worldwide, but there do appear to be a number of potentially beneficial uses, which have to be carefully thought out to make sure we are not putting anyone at risk, as I said before.

Mr. Putnam. Mr. Lloyd, prior to 1989, before EPA redefined a commercial product as a waste product that was therefore eligible for regulation, what were the primary uses of the phosphogypsum byproduct, and was it ever used in the construction of a building, for example?

Mr. Lloyd. Could I answer that construction thing first? Not in this country, but overseas at that same time, you were doing it in Japan with phosphogypsum for building products, wallboard and other structural members; in France, in Belgium; in Germany, at times they have used this for making structural members as well as wallboard. There was no real problem with that.

The biggest uses in U.S. history were agriculture. In California, you had a phosphoric acid plant, there is no gypsum stack. The phosphogypsum was used literally as it was manufactured. In the middle of the United States, you have some phosphogypsum stacks, most of those, there was some gypsum used for agriculture. At the time of the EPA ban, the only commercial application on roads was in Texas and at that time Mobil was actually building roads using phosphogypsum. We were still experimenting and going in a different direction than what they did. They had a different technique than what we were proposing to use.

There have been roads built all over Polk County where the mining companies were concerned, that they used phosphogypsum. There are untold number of parking lots at churches and at places like that, that were built with phosphogypsum because somebody at church worked for the phosphate industry, they could get the phosphogypsum free. You did have one company around here, one paving company, that worked with phosphogypsum all the time on this type of job.

That was about the uses of it.

Phosphogypsum had been used in other parts of the world, not in this country, to recover sulfur to recycle it to make additional sulfuric acid, particularly in South Africa.

But those are about the only uses I know of at that time.

Mr. Putnam. Is there a potential for use on unpaved roads, as far as strength and durability and the amount that is spent by local governments to maintain clay roads, unpaved roads in

rural parts, is phosphogypsum suitable for that purpose, assuming it were permitted?

Mr. Lloyd. Structurally, yes. This is one of the things that we got into in north Florida with Columbia County. The road that was built up there is an asphalt paved road with a phosphogypsum base. One of the things they wanted to do was to go into all of their dirt, unpaved roads, and take and mix phosphogypsum into the soil and then compact it. The work we have done with Dr. Chang indicated this road would stand up an awful lot better than what the untreated road would. But that never went beyond that point.

When you do this, you will have to face the possibility of some leachate of calcium and sulfur because gypsum is very slightly soluble. We have not done any tests to be able to tell you what that would amount to.

Mr. Putnam. And do you know what the industry spends today managing the existing phosphogypsum stacks?

Mr. Lloyd. I would not even want to guess.

Mr. Putnam. Does anyone else have a comment on the environmental or economic impact of managing the stacks?

[No response.]

Mr. Putnam. Well, with that, I would like to ask each of our first panel of witnesses to make any closing comments that you wish to make, whatever issues we were unable to get to or whatever you wish could come out of this. This has been a process, very long in the making. I can remember trying to work through this issue in the legislature. Growing up in this area, watching these mountains come up, it certainly is an important issue I think for us to resolve for the environmental and economic health of central Florida. All of you have devoted your professional lives to it, so at this time, it is an open mic, beginning with Dr. Shieh and letting Mr. Lloyd have the last word for our first hearing. Dr. Shieh.

Mr. Shieh. OK. Well, as I said earlier, the result of the study has supported to concept of use of phosphogypsum in landfill applications and if we were able to carry out the field study, by today we should have some conclusive findings available to interested parties. If there were any adverse effects that needed to be addressed, we would be able to identify. So my true belief is if we have something on the way and be able to provide solutions to an existing problem, then I think we should go ahead and do it.

I want to emphasize that this approach will not solve overall our phosphogypsum stack problem at all, but it will provide a solution to help minimize the existing problem. So we are still just waiting and waiting without any solution. I think we should go ahead and make a decision to do it. Thank you.

Mr. Putnam. Thank you, Dr. Shieh. Dr. Chambers.

Mr. Chambers. Thank you very much. I will be brief, I think I have said most of what I want to say.

I would just like to reiterate from my examination of EPA's calculations and my own calculations that I believe the doses and the risks to even the most exposed person are small on an absolute basis and very small by comparison to the natural variation in dose from background radiation. And truly in that context, of very little concern.

I would fully support Dr. Shieh and I would like to see some of these tests at least licensed so we can actually get and confirm one model or the other. And I really do not understand the lengthy process in licensing, and in my opinion, it would be unfortunate if the theoretical concerns over radiological risks were to prevent uses of phosphogypsum that would be of benefit to the people of the State of Florida and indeed the country. Thank you.

Mr. Putnam. Thank you. Dr. Sumner.

Mr. Sumner. Mr. Chairman, in summarizing, I would like to first of all draw the committee's attention to another use of phosphogypsum. Currently I hold a patent which was based on wallboard for making kitty litter out of gypsum. It is self-clumping, odorless kitty litter. It is doing very well in the market based on recycled wallboard. But if we were to use phosphogypsum, it would be even better than recycled wallboard. So that is another potential use.

I would like to just finally say that the maximum rate in agriculture should be figured into the risk assessment calculations as between 600 and 800 pounds of phosphogypsum per acre per year. That would be the maximum rate that it could be used in agriculture.

Thank you, Mr. Chairman.

Mr. Putnam. Thank you. Mr. Lloyd.

Mr. Lloyd. I guess I always find it interesting when you re-invent the wheel. Dr. Sumner has said something about using phosphogypsum with chickens, with the waste from chickens. It has got to be at least 10 years ago that I told the DEP in Florida that was one of the ways to stop the odors from a chicken waste. If you will go all the way back into the 1900's, you will find the same sort of thing was practiced, both on dairy farms and other places, except they used what was then called normal super phosphate. But all of the gypsum, when you made normal super phosphate, ended up in the normal super phosphate. The gypsum was what knocked down the odors, what stopped the phosphorus leaching, what did all of the other things.

So we are re-inventing something that we should have known a long, long time ago.

I do think the landfill is one thing that ought to be put on a priority track. This is something that virtually every time you see somebody trying to build a landfill, everybody starts hollering and shouting do not build it near me. So one of the things that would be very beneficial, also very cost-effective, would be to build landfills and use phosphogypsum.

The Institute looks at things from so-called applied research point of view. One of the things in the area of phosphogypsum that we look at all the time is the economic impact. So when we start recommending one of these things, we are not only recommending it because we think it is environmentally sound, we know it is economically practical, and that it will contribute to the Florida economy. So this is one of the reasons we support all of the things we have done.

One thing I would mention, and I am sure that Dr. Chambers will second me on this, every time we have been able to sit down with EPA in a full scale scientific discussion, we have ended up making some progress. But that is again--next to getting an exemption application, that is one of the hardest things to do that you have ever tried to do. We have succeeded twice in the last 20 years. So if there would be some way that we could do this and let some of the things that Dr. Sumner has seen, let some of the things that Dr. Chambers has seen be presented to these people, we could probably make some progress.

I think for the opportunity.

Mr. Putnam. I want to thank all of you before we adjourn this first hearing. I want to tell you how much we appreciate the expert testimony that you have given this subcommittee panel. It strongly reinforces the premise that utilizing phosphogypsum can be safe and less costly to taxpayers and as well as being environmentally sustainable. I appreciate your willingness to be here, some of you have traveled a great distance to share your knowledge and experience and thoughts

and in some cases frustrations, and I would like to invite you to participate in the second hearing as well. So for those of you whose schedules allow, I would like for you to remain and participate in that hearing also.

In the event that there may be additional questions that we did not have time for today or did not get to, the record will remain open for 2 weeks for submitted questions and answers. And with that, we will stand adjourned for 15 minutes and reconvene hearing two at 11:15. Thank you.

[Whereupon, at 11:03 a.m., the subcommittee was adjourned.]

PHOSPHOGYPSUM: SHOULD WE JUST LET IT GO TO WASTE: PART 2

MONDAY, MARCH 15, 2004

House of Representatives,
Subcommittee on Technology, Information Policy,
Intergovernmental Relations and the Census,
Committee on Government Reform,
Bartow, FL.

The subcommittee met, pursuant to notice, at 11:30 a.m., in the West Wing, Southwest Florida Water Management District Headquarters, 170 Century Drive, Bartow, FL, Hon. Adam Putnam (chairman of the subcommittee) presiding.

Present: Representative Putnam.

Staff present: Bob Dix, staff director; John Hambel, senior counsel; Ursula Wojciechowski, professional staff member; Juliana French, clerk; and Matthew Joyner, district director.

Mr. Putnam. The Subcommittee on Technology, Information Policy, Intergovernmental Relations and the Census will come to order. This is officially the subcommittee's second hearing on phosphogypsum entitled, ``Phosphogypsum: Should We Just Let It Go To Waste?''

In 1989, the U.S. Environmental Protection Agency promulgated a rule determining that the commercial product of phosphogypsum was waste product and banned its use for any purpose whatsoever.

Three years later, the EPA modified the rule to allow the use of phosphogypsum from north Florida for agricultural purposes.

Since then, only one other rule has been promulgated. In 1999, EPA raised the limit on the quantity of phosphogypsum that may be used for indoor research and development from 700 pounds to 7,000 pounds and clarified sampling procedures for phosphogypsum removed from stacks for other purposes. This was a step in the right direction.

Testimony provided for our first hearing, which we just concluded, suggests that the use of phosphogypsum can be favorable to farmers, cattlemen and taxpayers, particularly local governments, as a landfill cover, when used as a soil amendment, road base and again, landfill additive. Additionally, concern was expressed that the long-term adverse environmental effects of leaving phosphogypsum in stacks greatly exceeds any risks associated with its use for any purposes researched.

A number of other issues came forward that we hope to explore in this second hearing, including the delays in permitting for additional research and the inability to communicate effectively with the policymakers.

I would like to ask unanimous consent of the other subcommittee members to reseat the witnesses from our first

ED_005285_00000595-00025

hearing, so that we may benefit from a combined panel of expertise. Without objection, so ordered.

And without delay, I welcome our witnesses and look forward to your testimony.

As is the custom with the Government Reform Committee, all of our witnesses are sworn in. For those witnesses who were sworn in for the first panel, I would ask that you be sworn in again since this is technically a new hearing. And again, for any of our witnesses, if you have someone with you who will provide supporting testimony, slipping you notes, whispering in your ear, providing additional information for the benefit of the subcommittee, we would ask that they rise and be sworn as well.

So with that, please rise and raise your right hands.

[Witnesses sworn.]

Mr. Putnam. I note for the record that all of the witnesses responded in the affirmative.

Our first witness is Ms. Elizabeth A. Cotsworth, who is currently the Office Director of the Environmental Protection Agency's Office of Radiation and Indoor Air. She provides national direction for protecting people and the environment from harmful and avoidable exposure to radiation as well as protective measures and guidance for indoor air environments.

Prior to joining the ORIA, Ms. Cotsworth was the Office Director of the Office of Solid Waste from 1997 to 2002, after holding a series of positions managing national hazardous and solid waste programs.

She entered the EPA as a management intern in 1973, she holds a B.A. from Chatham College in History and an M.A. from the University of Virginia in Government and Foreign Affairs.

Welcome to the subcommittee. You are recognized.

STATEMENTS OF ELIZABETH COTSWORTH, DIRECTOR, OFFICE OF RADIATION AND INDOOR AIR, OFFICE OF AIR AND RADIATION, U.S. ENVIRONMENTAL PROTECTION AGENCY; HARLAN KEATON, ENVIRONMENTAL ADMINISTRATOR, BUREAU OF RADIATION CONTROL, FLORIDA DEPARTMENT OF HEALTH; AND DICK ECKENROD, EXECUTIVE DIRECTOR, TAMPA BAY ESTUARY

Ms. Cotsworth. Thank you, Mr. Chairman, for the invitation to appear here today. I will comment on the approach that the Environmental Protection Agency has implemented over the last 15 years to address the issue of protection of human health and the environment with regard to phosphogypsum.

EPA has specifically regulated phosphogypsum since 1989 with a national emissions standard for hazardous air pollutants called NESHAPS, authorized under Section 112 of the Clean Air Act. Radionuclides are listed there as a hazardous air pollutant. Radionuclides are a known cause of cancer and genetic damage. It is the processing of raw phosphate ore that specifically concentrates radionuclides into the phosphogypsum. Phosphogypsum contains naturally occurring radiation, as well as its decay products such as radium-226 and radon. Due to its health risk, its radon gas emissions in particular are the target of our NESHAPS regulation.

We strive to provide maximum feasible protection against risks to health from hazardous air pollutants, including radionuclides. We do so by trying to limit exposures such that an individual's lifetime excess cancer risk level is really no more than 1 in 10,000.

In our 1989 regulation, EPA specified stacks as the safest for phosphogypsum management. It is the use of stacks that provide appropriate risk protection with an ample margin of safety, as is required by the Clean Air Act.

Originally, there were no provisions for allowing

alternatives of the material, but petitioners approached us afterwards for reconsideration. We determined, considering all of the information available on potential exposures and the associated risk, that certain uses may be considered acceptable as long as those uses are restricted to limit the estimated lifetime risk to approximately 1 in 10,000.

We now allow three types of activities using phosphogypsum.

First, outdoor agricultural uses. For example, as a conditioner of soils with high quantities of salt or low concentrations of calcium or other nutrients, as long as the average radium-226 concentration is less than 10 picocuries per gram. For example, peanut farmers in Georgia apply phosphogypsum to their fields to strengthen peanut shells. Also, when several counties in North Carolina recently found farmland soils to have high salinity, in part because of Hurricane Isabel.

Second, indoor research and development activities using up to 7,000 pounds of phosphogypsum; for example, to study the production of road base and building materials.

And third, other alternative uses that are approved by EPA on a case-by-case basis.

Some activities do not meet the criteria for ensuring safety and health protection on a national basis. For example, we found that a generic national exemption for road building material could not meet the risk criteria. This is because of radium-bearing dusts, which are dispersed as the road surface degrades and radon emissions from the road itself. In addition, when road material is eventually removed, disposed or abandoned, additional exposures can occur.

As we review and consider the safety of new potential phosphogypsum uses, we work in partnership with our colleagues in State government, such as the Florida Department of Environmental Protection. In addition to potential exposure, our review carefully considers impacts on State legal authority and interests such as groundwater protection from any alternative use.

We have received several petitions requesting EPA approval of alternative uses for phosphogypsum. We are currently reviewing a petition for its use as a landfill cover at a municipal solid waste landfill in Brevard County, FL. We hope to have a response on the completeness of this application in the next month to 6 weeks. We are also simultaneously in the process of developing much needed guidance to further and clearly explain the criteria discussed in our regulations, specifically providing our sense of what information is required for a complete application that can then be evaluated for its support of a publicly and scientifically defensible decision.

We stress the importance of addressing radiation risk and giving confidence perhaps through monitoring, that other constituents in the waste, for example heavy metals, do not pose additional environmental concerns. Additionally, we seek to identify the benefits clearly associated with the alternative use and consistent with the principles of radiation protection, assure that potential exposures are justified and legitimate.

Managing phosphogypsum in stacks consistent with existing regulations is the best current management practice for most phosphogypsum. But we continue to be open to consideration of other beneficial and protected uses and remain supportive of research. Nevertheless, petitions submitted to the agency for such uses must clearly and fully demonstrate that the alternative use will be at least as protective as keeping the material in those stacks.

This concludes my prepared statement. I will be happy to

ED_005285_00000595-00027

answer any questions. Thank you.

[The prepared statement of Ms. Cotsworth follows:]

[GRAPHIC] [TIFF OMITTED] T5739.037

[GRAPHIC] [TIFF OMITTED] T5739.038

Mr. Putnam. Thank you very much, Ms. Cotsworth.

Our second witness for this hearing is Mr. Harlan Keaton. Mr. Keaton is an environmental administrator for the Bureau of Radiation Control, a branch of the Florida Department of Health.

Mr. Keaton has been an employee of the Department for 33 years. The last 20 years, he has served as the administrator of the statewide environmental radiation surveillance and radiological emergency response programs. He has received the Hammer Team Award from former Vice President Gore and the Board of Directors Award for Outstanding Achievement in the field of radiation protection from the Conference of Radiation Control Program Directors, of which he is an associate member.

Additionally, he is a member and former two time president of the Florida Chapter of the Health Physics Society. Mr. Keaton was a member of the Technical Advisory Committee at the Florida Institute of Phosphate Research and Chaired the E-35 Marson Committee of the Conference of Radiation Control Program Directors.

Welcome to the subcommittee. You are recognized.

Mr. Keaton. I would like to describe today what the Department of Health's limited role is regarding naturally occurring radioactive material in the environment, and specifically as it is associated with the phosphate mining industry.

The U.S. Environmental Protection Agency has primary responsibility for developing rules and national standards for handling phosphogypsum and waste issues. The Florida Department of Environmental Protection, under the authorization from EPA, also looks closely at the proper disposal and beneficial use of this material. As part of the Department of Health's mission to promote and protect the health and safety of all residents of Florida, we have a limited role in the monitoring of phosphogypsum. Through our Bureau of Radiation Control, we regulate the use of radiation and radioactive materials in medicine and industry. Please note, therefore, that our Bureau is only looking at the radioactive issues associated with phosphogypsum. We understand that there are also other environmental contaminants that can impact groundwater from the disposal and use of phosphogypsum, such as sulfates, sodium, iron, fluoride and trace heavy metals. These contaminants should also be evaluated when making beneficial use decisions about this waste.

The Bureau also has several environmental monitoring programs, including one that monitors the radiation levels on phosphate lands both before mining and after land reclamation. This program has been going on since 1986. The data we have gathered indicates a small--a very small--increase in radiation levels following reclamation of mine lands. However, please note that the pre-mined and reclaimed lands are not identical in makeup to the phosphogypsum, although there are many similarities, including the presence of naturally occurring radioactive materials.

Although the Department of Health does not regulate the

disposal or the use of phosphogypsum and has not been directly involved in research regarding the potential uses and possible health risks from the use of phosphogypsum, we do conduct some testing in the mining areas. Our staff have also served as advisors to FIPR to provide input on radiation related matters and advice on appropriate research areas. FIPR was established by the Florida Legislature to initiate, conduct or sponsor studies to minimize or rectify any negative impact of phosphate mining and processing on the environment and improve the industry's positive impact on the economy. FIPR is a public entity located within the Florida Department of Education.

One aspect of our direct involvement in assessment of health risks from naturally occurring radiation in the phosphate mining areas is the risks from indoor radon levels. In an effort to control indoor levels of radon, both the EPA and the State of Florida began developing mitigation techniques to be used in existing buildings.

In 1978, the State also embarked on a project to develop radon-resistant construction techniques for new homes built on reclaimed phosphate lands. Standards for new construction and the mitigation of radon in existing construction were developed between 1989 and 1995 by the Department of Community Affairs. These standards, called the ``Florida Standards for Radon-Resistant Construction'' are also included as appendices of the Florida Building Code. Again, although this effort is not directly related to the use of phosphogypsum, it shows that research can be performed and efforts can be taken to mitigate the risks associated with naturally occurring radioactive material and ensure that risk is at a safe level.

Studies of phosphate workers have not shown abnormal cancer rates and health reviews of populations living in previously mined areas do not indicate an increase or excess of lung cancers. More extensive research about the effects of exposure to phosphogypsum is needed.

In conclusion, it also makes sense to aggressively research appropriate and safe uses for this plentiful product. In Florida alone, we have approximately 1 billion tons in 24 stacks, with an annual product of 30 million new tons of phosphogypsum. We are interested in any scientifically valid research that shows possible health risks or lack of health risks associated with potential uses of phosphogypsum. We believe this is a significant issue that we could understand better through more research, research that can enable us to determine appropriate uses for this material and what steps are needed to protect the public's health and the environment.

We believe that the current practice of stacking the phosphogypsum has potential environmental and public health risks, as evidenced by unintended releases and spills and the recent need to dispose of millions of gallons of gypsum and acidic wastewater. Last year, the Federal Government granted the DEP permission to dispose of the treated wastewater in the Gulf of Mexico. We therefore support and encourage aggressive research to determine safe uses of phosphogypsum, while protecting the health and safety of the residents of Florida. Through this research, developments may allow for better roads, more efficient landfill covers, additional needed sulfur for the soil, and construction materials like safe glass, thereby providing a residual benefit to society.

I am happy to answer any questions that you may have.

[The prepared statement of Mr. Keaton follows:]

[GRAPHIC] [TIFF OMITTED] T5739.039

[GRAPHIC] [TIFF OMITTED] T5739.040

[GRAPHIC] [TIFF OMITTED] T5739.041

Mr. Putnam. Thank you very much, Mr. Keaton.

Our third witness for this hearing is Mr. Dick Eckenrod. Mr. Eckenrod is the executive director of the Tampa Bay Estuary Program.

Since joining the Tampa Bay Estuary Program in December 1990, Mr. Eckenrod has directed the development of an innovative management approach for Tampa Bay that seeks to balance economic and environmental concerns.

Before coming to TBEP, he was part of an inter-disciplinary team of scientists and engineers employed by the Southwest Florida Water Management District.

From 1984 to 1987, he advised the Manatee County Commission on natural resources issues as director of the Department of Land and Natural Resources. His responsibilities included mining regulation and management of county-owned conservation areas. He served the county as phosphate mining coordinator from 1980 to 1984.

He has also worked in the private sector as a specialist in water quality management and environmental impact assessment and an environmental engineer with various consulting firms.

A member of the Water Environment Federation, Mr. Eckenrod serves on the Executive Steering Committee of the Agency on Bay Management and a number of other environmental advisory and coordinating committees in the Tampa Bay region.

Welcome to the subcommittee. And you are recognized.

Mr. Eckenrod. Thank you, Mr. Chairman, for this opportunity to address the subcommittee on the subject of beneficial uses of phosphogypsum and some of the environmental issues associated with those uses. I am Dick Eckenrod, executive director of the Tampa Bay Estuary Program.

Tampa Bay is 1 of 28 estuaries of national significance participating in the NEP established pursuant to Section 320 of the Clean Water Act. Tampa Bay was designated an NEP in 1990 by President George Bush and has subsequently developed a cleanup and restoration plan for Tampa Bay. That plan is now being implemented by the program's partners in the public and private sectors.

The Estuary Program is an independent special district of the State of Florida, organized through an Interlocal Agreement under the authority of Section 163.01 of the Florida statutes. The nine-member governing body of the Estuary Program, known as its Policy Board, consists of elected officials or senior administrators from the cities of Tampa, St. Pete, Clearwater, the counties of Hillsborough, Pinellas and Manatee along with U.S. EPA, the Florida Department of Environmental Protection and the Southwest Florida Water Management District.

The Estuary Program does not generally take positions on environmental permits or other regulatory matters, but does endeavor to serve as a source of reliable information and unbiased advice to all interested parties. It is in that spirit that I offer the following comments.

Among the priority issues addressed by the Estuary Program are controlling excessive nitrogen loading to Tampa Bay in order to maintain water clarity and foster expansion of submerged aquatic vegetation or seagrasses in the bay; reducing chemical contamination of bay sediments and protecting relatively clean areas of the bay from contamination; and developing a long-range dredged material management plan for the bay that will minimize adverse environmental impacts and maximize beneficial uses of dredged material.

Reusing or reclaiming liquids and solids that in the past were considered waste materials and threats to the bay is a key element of the Estuary Program's strategy to achieve its water

quality and habitat restoration goals. The Program's local government partners, for example, have made major strides toward nitrogen load reduction by reclaiming domestic wastewater for irrigation of residential, commercial, agricultural and public properties. In addition to reducing nitrogen loadings to the bay, reclaiming wastewater is helping offset demands on ground and surface water supplies for public use.

Another Estuary Program partner, the Corps of Engineers, is selectively using dredged material from ship-channel construction and maintenance to create emergent wetland habitats, restore eroded beaches and improve the quality of submerged habitats in previously disturbed areas. Sediments once regarded as spoils or wastes are now being transformed from environmental liabilities into environmental benefits for Tampa Bay.

Managing the huge and ever-growing inventory of phosphogypsum in Florida similarly offers opportunities as well as challenges. Using all or a portion of the estimated 30 million tons of phosphogypsum generated each year for safe and appropriate uses could reduce the volume of contaminated process water that will ultimately need to be disposed of. And, as the recent experience at the Piney Point facility in Manatee County has shown, reducing the volume of stored process water also reduces the potential magnitude of accidental releases. Options for beneficial use of phosphogypsum should be actively pursued along with the research needed to reasonably assure protection of public health and the environment.

In addition to potential impacts on nutrient loads, evaluation of potential beneficial uses of phosphogypsum in the Tampa Bay watershed should take into account toxic contaminants that have been documented at various levels of concern in Tampa Bay. An ecological and human risk assessment conducted for the Estuary Program by Parsons Engineering Science in 1996 concluded that polychlorinated biphenyls, polycyclic aromatic hydrocarbons and specific metals--chromium, copper, mercury, nickel and silver--were priority contaminants of concern in one or more segments of Tampa Bay. Potential human health and environmental risks of contaminants of concern associated with phosphogypsum should also be thoroughly assessed before specific uses are approved.

In summary, beneficial uses of materials formerly regarded as wastes are now making important contributions to the recovery of the Tampa Bay ecosystem. Potential beneficial uses of phosphogypsum should be similarly explored, together with appropriate health and environmental risk assessments.

That concludes my prepared remarks.

[The prepared statement of Mr. Eckenrod follows:]

[GRAPHIC] [TIFF OMITTED] T5739.043

[GRAPHIC] [TIFF OMITTED] T5739.044

Mr. Putnam. Thank you very much, Mr. Eckenrod.

And before we go to questions, I overlooked a small item when we were administering the oath. If the individuals who were sworn in outside of our seated witnesses would please rise and identify themselves and their title for the record. So everyone who was sworn in outside our witnesses, if you would please come to the front row and we will start on the left and identify by name and position or title.

Mr. Rosnick. My name is Reid Rosnick, I am an environmental scientist with the Environmental Protection Agency. I am in the

ED_005285_00000595-00031

Office of Radiation and Indoor Air in Washington, DC.

Mr. Putnam. If you could step forward, please, so that we can get this for the record.

Mr. Button. My name is Rick Button, I am a health physicist with the EPA, Region IV in Atlanta, GA with the Quantitative Technical Support Section.

Mr. Putnam. Thank you.

Mr. Burkee. I am Brian Burkee, I am a research director with the Florida Institute of Phosphate Research.

Mr. DeGrove. I am Bruce DeGrove, I am director of regulatory affairs for the Florida Phosphate Council in Tallahassee.

Mr. Posey. I am Stan Posey, manager of environmental affairs for PTS Phosphate at White Springs.

Mr. Putnam. Thank you very much, and we will begin with our questions.

Ms. Cotsworth, your testimony--you said that the concern of the EPA was to make sure that any increased exposure was justified and legitimate. Did anything that was presented in hearing one lead you to believe that there is a scientific basis for changing the treatment of phosphogypsum from being a waste product to being a commercial product?

Ms. Cotsworth. We would be happy to sit down with the members of that panel to discuss specifically the points that they made, to work with them to determine if there is sufficient early information that would support a petition to the agency under the regulatory authority that I cited, and to work with them, again, in terms of what we require for a complete evaluation and what we would require in order to be able to thoroughly assess and make again a publicly defensible and scientifically defensible conclusion or decision.

Mr. Putnam. So they have your commitment then that you and your people will meet with them and their people to do this?

Ms. Cotsworth. We would be glad to. I know there have been frustrations, I think on both sides, but we certainly would be willing to sit down and be as clear and specific and informative as we can be.

Mr. Putnam. Until 1989, phosphogypsum was treated as any other item of commerce and sold for agriculture and was used locally, as was discussed in the first hearing, for any number of construction projects. What was the basis for the shift in policy from an item--where an item of commerce was suddenly treated as a waste product and subject to regulation?

Ms. Cotsworth. We were implementing the requirements of the Clean Air Act to control the risks of hazardous air pollutants, and our source controls were established as the legislation requires us to do consistent with all hazardous air pollutants. And in the 1989 rulemaking, we advised the public that we had found a basis to require management in stacks because of the potential for it to be incorporated into other products and be defused throughout the country such that we would be unable to ensure that the rate on emissions did not present an unreasonable risk. That was the basis.

Mr. Putnam. And an unreasonable risk in your opinion would be one that exceeds 1 in 10,000?

Ms. Cotsworth. Generally yes, the risk range that we used consistently for Clean Air Act regulatory decisions is between 10 to the minus 6 which is one in a million risk to the 1 in 10,000 number generally. And that 1 in 10,000 is also a risk level that we use in many other of our regulatory programs.

Mr. Putnam. The risk analysis that you used employed an assumption of 70-year residency for occupants of the hypothetical home. That is a value that is not supported by any available data and shorter residency times are used by your agency in other risk calculations. So why was this item chosen

for the 70-year residency risk calculation?

Ms. Cotsworth. The 70-year residency is actually, again, consistent with the assumption that we use in risk analyses for all of our Clean Air Act rulemakings and for many of our other rulemakings and regulatory activities. There are some decisions where a 30-year residence time is included but for the regulatory purposes, we generally use a 70-year residence time. And we have data that suggests that it is not inappropriate to use for phosphogypsum and farmer residence time.

Mr. Putnam. You have studies that suggest that it is not inappropriate to use the 70--what studies were done to justify that action?

Ms. Cotsworth. We have conducted studies, I believe that were associated with the 1992 and possibly the 1989 regulatory actions. I would be happy to go back and research and submit those particular studies and statements for the record.

Mr. Putnam. Well, I am just trying--the Federal Register in 1989 does not specify a reason for the ban, so I think it is important to know what action--what studies precipitated that action. And Dr. Chambers, in the first hearing, stated that your own handbook uses a 30-year risk model. Could you explain that difference?

Ms. Cotsworth. I believe that the handbook that is being referred to is used in regard to cleanup decisions associated with our so-called Superfund program. I cannot absolutely say for sure, but I believe that is the reference. But in terms of most of our regulatory decisions, including those under the Clean Air Act, we do use a 70-year timeframe.

Mr. Putnam. For actions under the Clean Air Act, you use the 70-year timeframe. And is that directed by law or is that an internal rule?

Ms. Cotsworth. I believe it is an internal approach, I cannot state with certainty. I will be glad to again check into that and get back to the staff.

Mr. Putnam. Why would there be such a dramatic risk calculation for a Superfund site which can be anywhere in a community and, you know, through recent legislation on brown fields and everything else, subject to other uses--why would there be such a dramatically different risk calculation for that than there is for Clean Air Act compliance?

Ms. Cotsworth. Well, the difference is largely a cleanup, a remedial situation dealing with contaminants that already exist in the environment as opposed to rulemaking, national generic level rulemaking, which are intended to be protective and preventative in nature.

Mr. Putnam. The calculations that you did use averaged the amounts of phosphogypsum used for soil treatment in California and in fertilization in Georgia and arrived at an annual application rate of 1,350 pounds per acre per year. Is there a practical basis for that application rate that you all used? Are you aware of any farmer who uses that much phosphogypsum?

Ms. Cotsworth. The determination was based on data and information that was submitted to the agency and that is included in our background information document. And again, we were developing a national regulation, which is generic in scope and application rates across the country do vary, according to crop type, soil conditions, purpose of the application. And for us to be generally conservative and take into account the possibility of reasonable worst case exposure assumptions, we did use data and information provided from California in determining the application rates.

Mr. Putnam. Is there not an ability for you--you referred to the general application rate in a general generic rule to be applied nationwide. Is there not a basis for you to develop or promulgate a regional rule that would apply to sodic soils in

the western United States and a different one that would apply to the treatments that are used in the southeastern United States, just as other aspects of EPA promulgate different labels for different crops in different regions?

Ms. Cotsworth. It is possible; however, it becomes very difficult to implement, difficult to enforce and it transfers, in large part, the burden of implementation to the farmers and the small agribusinesses that would then have to spend the time and effort to be careful in regard to the use of a product as opposed to us regulating the content from the start.

Mr. Putnam. I appreciate your sympathy for the farmer and small business, but EPA has never hesitated to transfer that burden in the past.

The soil treatment and fertilization, two unrelated practices, why were those two unrelated practices used to justify the ban for fertilization? Again, would it not be reasonable to have a rule for fertilization and a rule for soil treatment?

Ms. Cotsworth. Again, as I just indicated, the agency concluded that in order to provide protection for the possible most reasonable worst case scenario, that it was not appropriate to make that distinction.

Mr. Putnam. That is a fairly subjective thing. How do you know what a reasonable worst case scenario is? I mean, if you use this high concentration for sodic soils but you only do it once and then you are done for decades, if not forever, and then in the case of the peanut growers, they are using it every third year, is it the judgment of EPA's scientist, is it peer reviewed? How do you come about determining a reasonable worst case scenario?

Ms. Cotsworth. It is based on a risk assessment that is conducted according to the risk methodology that is in general use across EPA. There may have been some changes in methodology improvements over time since the 1989 and 1992 rulemakings; however, the risk assessments that were conducted at that time were consistent with all of the agency's practices and policies regarding risk assessment, including the scenarios, media transfers and how to use our data. Those risk assessments are normally, as with all of our background documents, are part of the public docket that is associated with public comment and notice rulemaking. They should have been available for public review at the time of the issuance of both the proposed and the final regulations.

Mr. Putnam. Well, let us come back to Florida for a second. What is the basis for banning north Florida phosphogypsum for roads but not for agricultural purposes when the road bed use has a lower risk than agricultural use? In other words, you have said it is OK to spread it on the fields that in a rapidly urbanizing State have a high risk of being homes in our lifetime, but banned it from a road bed usage, which is probably--which is highly unlikely in this State and most any other. What is the basis for that?

Ms. Cotsworth. Well, we did evaluate, as I said, generically road building in the 1994 regulation and we did find that certain exposures would lead to excess cancer rates, in excess of the risk range that we specified, and that in fact road bed usage did have a higher risk than actually agricultural usage.

Mr. Putnam. What roads were you testing to make that determination, what tests, what studies indicated that the cancer rate--the risk rate would be greater?

Ms. Cotsworth. The studies are detailed in our 1992 background information document. I apologize, I cannot personally speak to the specific studies that are accounted for here.

ED_005285_00000595-00034

Mr. Putnam. Does your colleague know?

Voice. No, I am sorry, I do not. I would have to look through the actual background information.

Mr. Putnam. Well, could you do that while we move on and we will come back to you.

Mr. Lloyd, do you know what studies the EPA used for their 1994 rule?

Mr. Lloyd. Some of the things that are mentioned we have never been able to find in the BID documents, so I do not know. We would be interested in finding the data that we requested in 1995 as to how they did the risk assessments for the 1992 rule. We have never been able to get the documents to show what the actual calculations were and it would be appreciated if we could get them.

Mr. Putnam. Is that type of document available to the public, Ms. Cotsworth?

Ms. Cotsworth. The public record for that rulemaking should still be available. What I cannot personally attest to is whether the documents or calculations that were just referred to are in that rulemaking record. Again, we do have high standards for the documentation and technical support documents to be included in our public docket and in our--and referenced in our preambles to our regulations. I apologize that, not having been with that office when the 1989 and 1992 regulations were promulgated, and at this point I have not seen those entire rulemaking dockets to be able to say specifically whether what was just alluded to is there, but I would certainly hope so.

Mr. Putnam. I would hope so too and I will make this my official request for those records and supporting documents and working papers as well, and we look forward to receiving those.

Why does EPA make atypical assumptions when calculating risk assessments for phosphogypsum in the 1992 ruling that are as unreasonable as those used in the 1989 rule that require correction only after a successful challenge?

Ms. Cotsworth. Again, the regulatory process allows for public input, public participation, particularly in regard to the way our proposed and then final regulations are crafted, giving people the opportunity to comment on the technical information upon which our decisions are based. Certainly the additional input that was received by the agency post-1989 was found to be useful for making subsequent regulatory modifications and we always remain open to new information, new data for consideration as to whether we need to improve or change our regulations, or in this case, because we have a petition process, to be able to use the petition process to exercise regulatory flexibility.

Mr. Putnam. And how long does that regulatory flexibility usually take to work its way through the process?

Ms. Cotsworth. It probably takes longer than the petitioners here would have liked. And we have not approved any petition to date. In part, that is probably due to change over in our staff and lack of clarity for the petitioners as to what we really need in a petition application. In some part, it is also due to the amount of time that it has taken for petitioners to respond to our data requests and our requests for more analyses.

Mr. Putnam. And do you know how long it took them to respond to your requests, the petitioners? How long did it take for them to respond to your requests for additional information?

Ms. Cotsworth. I believe in some cases there has never been a response and in some cases, it has taken many months.

Mr. Putnam. And with regard to Dr. Shieh's request for a permit to move forward with phase III, that was a 4-year and

still counting pending request--it seems to me this is unnecessarily adversarial. You have a group of credentialed, published, highly regarded scientists pursuing a line of research. In other words, they are seekers of information, of knowledge, of hopefully a solution to what we believe is a problem in the stacks. It would seem to me that at bare minimum for research purposes, the EPA would embrace that type of search for knowledge. Recognizing your own limitations as an agency and personnel constraints and funding constraints and everything else and the myriad of environmental issues you have to deal with, it would seem that when you have a group like this, and undoubtedly they are not the only ones, that that would be something that you would really embrace and join hands and move forward to solve an environmental problem.

I mean, I think everyone would admit that is not really how it is. I mean it has become this adversarial issue for years. I mean it predates me but as recently as 5 years ago in the legislature when we tried to work through this. You can never find anybody to give you an answer, you can never find anybody that seems really interested in working to make it work. And that is the rub, that is the real frustrating part here.

We have all kinds of questions here about why things went the way they did and why they have not been answered and why we are waiting 4 years just to be able to dig a plot to research landfill material. I mean we are not talking about cancer drugs here, we are not talking about distributing something to every mouth in America, we are talking about allowing research to go forward. And for some reason, whether it was you or your predecessor or the agency's culture, there is this adversarial issue. Help me understand that or please convince me that is not the case.

Ms. Cotsworth. I agree, it has been adversarial and what I believe and I believe the new administrator wants to make sure is that there is collaboration and honest dialog. You talked about the 4-years for review of Dr. Shieh's petition. Last June, members of my staff came here and had a meeting and basically indicated that what we had already in hand did not discuss the very issue of most concern to us, which was radioactivity. We have had a resubmission, additional information since December of last year, and we are actively reviewing that petition right now and at the same time trying to develop useful and clear guidance for all the petitioners in regard to what we expect relatively to again a complete application and one that will then support a final and clear decision.

I too believe that the process should be finite in terms of time, it should be transparent for everyone, the petitioners as well as others, including the general public who may have an interest, and that a decision is rendered. It may not necessarily be the decision that someone wants but I want to be able to give someone a final yes or no answer on the petition and to be able to tell them clearly why it was the answer that it was, so that they can understand and that we can again defend it in the public view and it will withstand scientific and technical challenge.

Mr. Putnam. There clearly are a lot of reasons why this has become a problem. But a change of administration is not one. When you look at the EPA and the number of employees that change from administration to administration, no matter who the President or the Administrator is, it is minimal. I mean this is a professional staff issue. The political appointees are not running road tests, road bed tests on radium-226. Regardless of who the Administrator is or who is in the White House, there ought to be some cultural openness to research and the search for answers.

Prior to EPA's 1989 rule banning the use of phosphogypsum, EPA conducted public hearings on whether or not to put layers of soil on top of the stacks to reduce the radon emanation that might be harmful to the people living in the vicinity of the stacks. Those public hearings concluded that the risks did not justify that action.

Now if the risk of having a multi-million ton concentration of phosphogypsum did not justify sprinkling top soil over it to reduce radon emanations, why would the risks exist in sprinkling phosphogypsum in central Florida agricultural fields or in building a road bed out of it?

Ms. Cotsworth. I am not personally aware of the public meetings or hearings to which you refer. So I am unable to comment on that. But certainly as we consider additional uses, we have to look at a variety of scenarios and pathways through which people are exposed. And the presence of phosphogypsum in roads and agriculture can sometimes present different exposures than stack management and each one needs to be evaluated accordingly and appropriately.

Mr. Putnam. But you said radioactivity is the real issue. I mean that's really the issue.

Ms. Cotsworth. Right.

Mr. Putnam. And so 40 million tons stacked, to me just common sense would say that radioactivity would be a greater issue in that concentrated form at that scale--that has to be a larger issue than when it is evenly spread in a road bed or on an agricultural field. And these are from the public hearings that your agency had prior to the 1989 rule.

Ms. Cotsworth. Again, I am just not familiar with those public hearings and the situation that is being described, but again, it is looking at different exposure scenarios and certain management controls that are in place relative to the stacks that would not be present in other uses.

Mr. Putnam. You were provided these questions in advance of this hearing.

Ms. Cotsworth. That is right, and between Friday afternoon and today, I could not find any reference to the hearings that were mentioned.

Voice. Congressman, I could provide some light on that question.

Mr. Putnam. Please. Speak into the mic, come forward please and speak into the mic.

Mr. Button. Richard Button. With regard to the soil on top of the stack, what we found is that on a stack, due to weight and volume, it creates its own cap, so putting soil on top of a stack does not reduce the radon emissions any more. And we find that the radon emissions tend to be greater on the side where the cap is broken up, which would explain why if you spread it out on farmland, the radon emissions would be higher than or equal to what they would on top of the stack.

Mr. Putnam. Thank you.

When did EPA last visit the phosphogypsum stacks to get a read?

Ms. Cotsworth. I believe staff from my office, during their visit in June of last year, actually visited a stack.

Mr. Putnam. And did you test their level of radiation?

Ms. Cotsworth. It was not a compliance visit or any kind of enforcement visit, it was for the purpose of information sharing relative to the petition process and getting a better understanding and appreciation of the problem and the issue.

Mr. Putnam. And as part of that information sharing, did you all test the stack?

Ms. Cotsworth. No, not that I am aware of.

Mr. Putnam. Mr. Lloyd, do you know if they tested the stack while they were here?

Mr. Lloyd. The stacks were last tested prior to 1989, as Rick can attest to.

Mr. Putnam. And not since then?

Mr. Lloyd. Not at all that I know of.

Mr. Putnam. If radioactivity is the issue, and we have 24 stacks around the State, it is not a big enough issue to have an ongoing radiation testing program?

Ms. Cotsworth. The NESHAPS that I referred to has been delegated to the State of Florida and I believe any monitoring would be conducted by the State. We have not--and I will look to Dick for some confirmation on this, I do not believe we, EPA, have done any oversight inspection or testing.

Mr. Button. That is correct.

Mr. Putnam. OK. You are from the air quality/radiation piece of EPA, is that correct?

Ms. Cotsworth. Yes, I am.

Mr. Putnam. Is there another piece of your agency that deals perhaps with water quality that is concerned about the concentration of these stacks and the Piney Point incident and the potential ecological hazard that stacking phosphogypsum presents?

Ms. Cotsworth. I think it is safe to say yes, we are all concerned about what happened last year at Piney Point.

Mr. Putnam. Well, but it seems to me that your piece of the EPA has determined that--at least in 1989, you determined that it is safer to stack it up than it is to spread it out. But is there another office in another wing of Atlanta's regional headquarters or some place in Washington where the water quality people are saying we have a real problem here. We have hundreds of millions of gallons of acidic water building up in these stacks that we might need to do something about. Is there coordination within EPA between air quality and water quality as it relates to gyp stacks?

Ms. Cotsworth. There is within the regional office, which was the group that dealt primarily with the Piney Point situation. I know Mr. Button here was involved as well as our Region IV emergency response personnel. I have not been approached by the EPA water office in regard to phosphogypsum during the time that I have been office director. But I would certainly not only coordinate with other State and appropriate agencies in regard to a phosphogypsum use application, but I would have to consult with my counterparts across EPA in terms of any concerns or issues that would arise that deal with their statutory responsibilities and the programs that they implement.

Mr. Putnam. Mr. Button, could you please come back to the microphone, since you were part of the emergency response to gyp stack management that occurred last summer?

Are you aware of a multi-disciplinary approach to managing these?

Mr. Button. Yes, when Superfund emergency response in Region IV Atlanta, they were asked by the State of Florida to provide assistance and when they found that phosphate plant had some low level radiation, I met with them and talked with them and gave them some input on the radiation risk associated with it, and also talked to their water people and everybody else that could provide input for their response.

Mr. Putnam. Are you aware of any reports that the water people, as you put them, any conclusions that they arrived at that perhaps managing the stacks as we do today might not be the best approach from a water quality perspective?

Mr. Button. No, I am not, but the Superfund emergency response people may be. I am not aware of that.

Mr. Putnam. Could you please, when you get back to the office, see if that information exists? I would like to make

that official information request.

Mr. Button. Yes, I can do that.

Mr. Putnam. So we can review their conclusions as it relates to their opinion of our management of phosphogypsum stacks.

Mr. Button. Well, they officially made a decision to dump the water into the bay, so I'm sure there is some documentation to support that. So yes, I can followup on that.

Mr. Putnam. And assuming another rainy season, we might have to dump some more into the bay. So it becomes an ongoing water quality environmental hazard that does not appear as being necessarily shared with the air quality folks. Thank you.

Mr. Keaton, in your testimony, you mentioned that the State of Florida developed standards for radon resistant construction. Could you describe those in some detail and tell us how or if they might foil the 70-year residency assumptions that EPA used in their risk calculation?

Mr. Keaton. Let me caveat that by saying there was a lot of work going on at the time. The Florida Institute of Phosphate Research had a program where they were doing mitigation in homes, they actually built some homes. Florida and the Environmental Protection Agency at that time were developing mitigation techniques and eventually that turned into a project where new construction was to be used on reclaimed phosphate lands.

What basically these construction techniques do is prevent radon--or at least reduce it significantly from getting into the home and also lowering through the slab and elevated crawl space, lowering the gamma levels that could possibly be in a home. So these techniques would be very effective if you were to build a home on phosphogypsum or reclaimed phosphate lands.

Mr. Putnam. Does the Department of Health conduct their own risk calculations in the everyday work of your oversight of health and safety issues for the State?

Mr. Keaton. We do when there is an emergency situation, when we see major problems. There has been a lot of work that has already been done in this area, especially on the workers at the phosphate mines. We have looked at areas like the Cornet, I am sure you are familiar with that, we have also looked at Stouffer Chemical, these areas, and have not yet to date found elevated levels.

As far as an area-wide study on all the people in this area; no, that has not been done. But by that same token, we have not seen any levels that would indicate that would necessarily need to be done.

Mr. Putnam. But could you please refresh my memory on what you found in your health studies of the phosphate workers in populations living in the previously mined areas?

Mr. Keaton. They did not show any increase in lung cancers or any health effects. As a matter of fact, there were many studies done, there was--I have them here--I mean I do not have the studies, but I have the information, if you would like to have it.

Mr. Putnam. We would. Could you please, if you would, tell us if you believe the differences in the north and central Florida phosphogypsums are significant enough to allow the use of one and ban the use of the other?

Mr. Keaton. Well, there is a radiological difference, but we are looking at very low levels of radioactivity. The Environmental Protection Agency has done risk assessment on that and these are models. OK? You put information in, you get information out. If you look at these models and you change the parameters that you use, it would seem that from what we have seen from the SENES reports that, no, there may not be a problem.

What we would like to see is the EPA and the FIPR come together on this and make decisions on what uses and what risks are going to be acceptable and we can go from there.

Mr. Putnam. You know, let me perhaps go to one of our scientists. Again, help us understand the difference between the north Florida and central Florida in terms of the number of picocuries and what that really means in the context of atmospheric radiation or just inherent radiation that exists today. Give us some context for that, if you would.

Mr. Chambers. I will try first. I am sure Mr. Lloyd or others will correct me.

I believe north Florida has a radium content in the order of 10 picocuries per gram and central Florida phosphate perhaps might be 26-27, something like that. So that is about two and a half times the radium-226 content. All other factors being equal, the rate of release of radon would be proportional to the concentration of radium-226. And that is why it is so important in looking at these risk assessments, whether it is EPA's or ours, to be reasonably conservative but not unrealistic or not unreasonable. And I think it was quite clear from Dr. Sumner's discussion this morning that there is a practical upper limit on the rate at which phosphogypsum might be applied, for example, to a farmer's field. And that is, for example, a ratio of 2,700 to 900, 2,700 being the upper 95 percentile as determined by EPA. That is larger than the difference in the radium-226 content.

So basically with any reasonable application rate and even following EPA's methodology, there should be no practical difference in the risk that would result from radium and radon.

Mr. Putnam. And Mr. Lloyd, do you or anyone with you have any additional information on that as it relates to how that compares to other activities that might lead to radiation exposure?

Mr. Chambers. I will come back to that as well. I do not have my litany of comparisons in front of me. I think I said earlier that at my age, I have a risk of about one in a million dying from natural causes during this hearing. In any event, if you look at EPA's risk range of 1 in 10,000 lifetime, that is approximately equivalent to one in a million risk per year. So my 1 hour or 2 hours here from natural causes would be a risk of one to two in a million of passing away from natural cause during this hearing.

Similarly, if I was a smoker, and I am happy I am not, smoking somewhere between one and two cigarettes, that is all it takes, would be the kind of risk that you would get, that would result in a risk of one in a million. Similarly, if I was flying from Tampa to Colorado to go skiing and return, that kind of flight would incur an extra radiation risk in the order of one in a million. Here, the extra radiation is from outer space from cosmic rays, because as you go up in the air, higher in the altitude, the protection from the air from outer space cosmic rays is less. So basically a risk of one in a million is about the same as my chances of dying, it is about the same as a return flight from Tampa to Denver, it is about the same as smoking a cigarette or a cigarette and a half.

Mr. Putnam. A cigarette per year?

Mr. Chambers. No, one cigarette.

Mr. Putnam. In your lifetime.

Mr. Chambers. That is a risk of one in a million.

Mr. Putnam. Let me see if I can shuck the corn a little bit here. [Laughter.]

Are you saying that if you did stay in a house 18 hours a day, 7 days a week for 70 years and if you employ this model that EPA has constructed for phosphogypsum, even if you did do those things, it is the equivalent exposure to radiation as

flying from here to Colorado to go snow skiing?

Mr. Chambers. Plus or minus the uncertainties, I believe that is about correct.

Mr. Putnam. So even if you do employ their maximum risk model, you are still talking about negligible risk compared to every other normal activity.

Mr. Chambers. Yes. As I indicated earlier, I feel that yes, there is a risk, it is a theoretical risk, but to me it is incredibly small and from my perspective, of no consequence because you are looking at an annual risk of about one in a million which converts to a lifetime risk of 1 in 10,000 and that is what we are regulating this industry to.

Mr. Putnam. Ms. Cotsworth, is that the typical benchmark that you all use in promulgating rules?

Ms. Cotsworth. Basically our decision is consistent with the approach that the agency takes in regard to its regulation. Our philosophy is that regardless of the background and the risks that already exist, that we are required to take action to prevent additive additional risk over and above what people are already exposed to.

Mr. Putnam. Additive risk----

Ms. Cotsworth. Any incremental risk that is within our purview, we try to control.

Mr. Putnam. Any additive risk above 1 in 10,000, greater than 1 in 10,000, or any additive risk?

Ms. Cotsworth. Any additive risk. We look at an excess cancer rate of 1 in 10,000 as the basis for possibly regulating.

Mr. Putnam. Is that an internal decision or is that set by law?

Ms. Cotsworth. In regard to, again, radionuclides as a hazardous air pollutant, there is a long history regarding the Clean Air Act implementation, the so-called benzene rule, court decisions that indicate that the agency is appropriate to be looking at excess risk in terms of 10 to the minus 6 and 10 to the minus 4 range and applying a margin of safety. So that has been defended both in court and in other regulatory decisions.

Mr. Putnam. But you just said that you all attempt to control any additive risk, even I assume lesser than that 10 to the minus 6.

Ms. Cotsworth. Right, we actually look at a range of one in a million and very often we back off from that to the 1 times 10 to the minus 4. In some cases, 3 times 10 to the minus 4. It's not an absolute hard line but it is generally 1 times 10 to the minus 4 in our regulatory decisions.

Mr. Putnam. I am sorry, go ahead.

Ms. Cotsworth. No, that is fine.

Mr. Putnam. Do you believe that their research is correct, that their findings on the risk are what they say they are?

Ms. Cotsworth. I would like to have the opportunity to look at it more thoroughly and look at the assumptions that were used, again, the scenarios to see how the studies and the research do compare against the risk assessment methodology that we used. It sounds intriguing.

Mr. Putnam. And if that is the case--well, I think they are dying to share it with you. But if it is correct, would that be the basis for changing the rule--would that be an adequate basis for changing the rule? Is their research adequate or do you have to go back to EPA and duplicate their research or do you accept them as accredited, certified, legitimate researchers?

Ms. Cotsworth. We would--I would not be able to say yes, we would revisit the regulations based on what I have heard today. We do not at this point have what we consider to be sufficient and compelling reproducible data and information that suggests

the need to completely overhaul the regulation. We are open to receiving data and information and assessing whether it is sufficient and adequate. We also encourage people to use the petition process that we have already set up. Since the regulation development process in the agency probably takes at least 5 years, the fact that we have an administrative option that is built into the current regulations, the agency has a preference, as I believe I stated before, for using the administrative procedures that are available to provide the flexibility and the relief on a more site-specific or region-specific, use-specific basis. And therefore not undergoing the very long laborious regulatory change process over which there is no control as to the outcome.

Mr. Putnam. Do you have a list of the information that they have not submitted or that you believe is insufficient, that they could check off. These are the things that EPA definitively says they must have? Do you have that?

Ms. Cotsworth. We have correspondence with certain individuals in the record. We are working at the same time as we are processing the current petition, Mr. Rosnick, who is behind me, is the staff person assigned to that, and he is also, by virtue of reviewing that petition, trying to develop a quick, easy-to-use, simple guidance, probably no more than a fact sheet, that can more readily and clearly indicate what are the requirements that we have for, again, a complete application, which then can be thoroughly evaluated.

Mr. Putnam. Is the definition of a complete application a moving target? Is that what I am hearing you say, that you are trying to put together a fact sheet, but as of now, nobody really knows what meets your definition of complete?

Ms. Cotsworth. The requirements that are in the regulations are very limited in their definition. We are trying to provide the definitiveness that the petitioners need, and again, based on our experience with working with the petitioners, they do need additional guidance from us as to what are the elements of the petition that are of most concern to us. As we indicated last June when we were here, we really want to know about the radioactive content and the issues related to that. We want to see if there is possibly any monitoring information that could be used to evaluate whether there are any other environmental hazards posed by the activity, the use or the research.

I agree it would be ideal if that guidance had been prepared some time ago. I cannot tell you why specifically it has not been, but it is important enough for me and my management team in the Office of Radiation and Indoor Air to say that this year, we want to provide our petitioners with good guidance so that they can develop a petition that is as quickly as possible able to be declared complete and then is ripe for that technical evaluation. And we commit to working and being in dialog with the petitioners, so again, they can clearly understand, as opposed to hearing it from, you know, a letter subsequently in terms of additional needs that still need to be met.

Mr. Putnam. So you certify that their application is complete and then you have to go evaluate it on its technical merits?

Ms. Cotsworth. Yes.

Mr. Putnam. And where would you do that analysis? You don't have phosphogypsum in your office in Atlanta, you don't have it on Pennsylvania Avenue, so what laboratory does that occur in?

Ms. Cotsworth. It may or may not occur in a laboratory. A lot of the review would be actually, again, evaluating and reviewing the documentation and the information that has been submitted on paper. We probably would want to come and visit with the petitioners and see some of the situations that they

are talking about, we would ask what kind of monitoring data they have and can make readily available to us, what kind of monitoring information perhaps the State regulatory authorities might have. But we do not necessarily use a lab, but we will use, again, risk assessment methodologies----

Mr. Putnam. So if you certify it as complete and after visiting with the petitioners, it would be their research that you accepted after some review--if you certified it as complete and you made that determination, you would not recreate the wheel, you would work off of the research that has been done in Florida, is that what I am hearing you say?

Ms. Cotsworth. That is right. And we might suggest some--as I believe was alluded to earlier, perhaps some controls, institutional controls, that might, in conjunction with the data and the science and the information, serve to again ensure that there is no unacceptable risk, that the risk is equivalent to the risk that the stacks pose right now, and go into our decisionmaking.

Mr. Putnam. The fundamental policy you are working off of, correct me if I am wrong, is that the stacks are inherently safer than any of the alternative uses proposed.

Ms. Cotsworth. As of this time, yes.

Mr. Putnam. And so the standard that the petitioners----

Ms. Cotsworth. When they are managed in accordance with current regulations.

Mr. Putnam. OK. The standards that the petitioner must then rise to is not that the alternative use is safe, but that its benefits outweigh the benefits of keeping it stacked up behind us here, is that correct?

Ms. Cotsworth. We look at the benefits. It has to be equivalent in terms of the risk. We look at risk to human health and the environment and it has to be in a way that we can translate to safe and protective of human health and the environment, which is no greater than a 1 times 10 to the minus 4.

Mr. Putnam. But they have to prove though that it is a better use than the being stacked up, not just that it is effective and safe in the landfill, not just that it is safe and effective in a road bed, not just that it is effective and safe as an artificial reef or in a glass container on a rocket to Mars. They have to prove that it is better than being stacked up, because that is the fundamental policy that you are weighing against.

Ms. Cotsworth. It has to be a use that is beneficial, a use for which there is a market, that there is a----

Mr. Putnam. Or that a market could be created from, whether there is an existing market.

Ms. Cotsworth. Or that we have some reasonable assurance that a market could be created for. There are situations in regard to other wastes that I am aware of where not all uses would be considered beneficial and legitimate.

But our bottom line is the risk.

Mr. Putnam. Are you familiar with something called PATHRAE?

Ms. Cotsworth. It is a model that my office relied on in regard to I believe the 1992 and subsequent rulemakings. That is as much as I know about PATHRAE.

Mr. Putnam. So it is the EPA's model for risk assessment, or it was at least in 1992.

Ms. Cotsworth. It is a model I believe. I may be able to ask--I know it is cited in this document. I apologize, I cannot go technically any further in discussing PATHRAE.

Mr. Putnam. But it is the model that you used to promulgate the rule in 1992, it is the research model that you used, correct?

Ms. Cotsworth. It was used. I cannot tell you whether it

was the only model or not, but it was used.

Mr. Putnam. But you used it, so we assume that you would accept it, it is a pretty good model if you used it in 1992. Has any of this additional research been done using the PATHRAE model so that we could compare apples to apples, Dr. Chambers?

Mr. Chambers. If I might comment. In 1998, it was, I believe, we did a very detailed risk assessment for FIPR on using phosphogypsum for roads and agriculture. And as a first step, we thought we would try and benchmark our models against the models used in the 1992 BID and there were in fact two models, PATHRAE which is referred to as a multi-media pathways model, it takes air and soil ingestion; and I believe in some cases EPA complemented the PATHRAE model with a model called MicroShield, which is another widely used model for gamma radiation.

I do not have time here, but with some effort, we actually had some difficulty in tracking down the actual inputs that EPA used, but we were able to, in the end, reproduce their 1992 BID results plus or minus a few percent. So as a first step, we did reproduce them.

Then basically, because these models were quite awkward to use, we did a screening calculation using other regulatory models. We continued to use MicroShield plus also the models by NRC which were a bit more advanced at the time and easier to use, and for the same inputs, we could benchmark those also to the earlier PATHRAE. When we did a screening using the NRC models, we again came up with the same conclusions that the other pathways were negligible and it was really radon and gamma that were the issue.

So yes, we have been able to test them. We can, with the same assumptions, reproduce the EPA's numbers.

Mr. Putnam. Ms. Cotsworth's concern is that the models that are being used in this research may differ from EPA or may make certain assumptions that would not be the assumptions that they would make if they were running the same risk calculation. I am paraphrasing you, but what have you done in your research to ensure that it is something that the EPA would accept, that the models are credible, that they are using the right assumptions and that it is good science?

Mr. Chambers. There is a whole history to this. As I mentioned before, we were able to benchmark our model. By benchmark, I mean get the same results for the same inputs to the EPA's models. And then to move forward, we did more than EPA with regard to pulling together information that is relevant to the situation in Florida for the soil application rates, road construction methods, house construction methods, indoor radon as it relates to soil radium-226 levels. And this is actually based on data that is documented in our report. I quite strongly believe that if we had the opportunity, we could convince EPA quite readily that our models were reasonable. It might be more difficult to convince them that our assumptions are appropriate; for example, the 70-year residency and this kind of thing.

However, I would like one final comment, to add that there is an inconsistency within even the radiation side of things between 70 years and 30 years, but also between Office of Radiation Programs and Office of Solid Waste. As I mentioned earlier, in 1999, when EPA did an examination of potential hazards from using fertilizer, they actually used a farm residency of 17 to 18 years, which is yet a different number.

So I think--I believe we can demonstrate good science behind our models and indeed EPA is moving toward the kind of modeling that we did, which uses Monte Carlo calculations to take account of uncertainties and I think EPA is moving in that direction. I think where the bigger challenge might be is

arguing or discussing what the appropriate assumptions are, and residency, for example, is one of them.

Mr. Putnam. So could you please clarify again what you do for the United Nations? That was in your biography, about the UNSCEARs?

Mr. Chambers. The UNSCEAR is the United Nations Scientific Committee on the Effects of Atomic Radiation was created in about 1955 by the United Nations, and I believe there are 26 countries, could be 27 including the United States and Canada and Britain and Germany and Russia and Japan and China, etc. And the responsibility of this group is to periodically--typically every 4 to 5 years--review all of the new verified, published, refereed research on the occurrence of radioactivity in the environment, and most importantly the health effects. This includes dosimetry and epidemiology. These documents are produced every 4 to 5 years and are used and referred to frequently by the U.S. National Council on Radiological Protection, by the U.S. EPA for that matter, by the International Commission on Radiological Protection, to whom the EPA often refers.

And it is an honor, but it is an agony. Consultant is basically volunteer time and my task right now is to revise, actually write the next UNSCEAR report on radon health effects.

Mr. Putnam. So we are not talking about some fly by-night backyard outfit here, we are working for the United Nations. And coming from the Congress, that can be sort of a frustrating group to work with, so you are to be commended for doing it.

But the models that you have developed, the work that you have done is often referred to by EPA, is that what I heard you say?

Mr. Chambers. The kinds of models that we have used, which include Monte Carlo calculations, which take account of uncertainty, have very much been used by EPA, and EPA I believe is moving more toward more routine use of these models because I am different than my colleague beside me, I may eat more, I am bigger, I may breathe more, and these models allow you to actually take account of difference in breathing rates and weight and this kind of thing. And it is the state-of-the-art that we have in modeling today.

Mr. Putnam. Thank you. The Tampa Bay Estuary Program coordinated a conference call for the EPA with more than 30 marine scientists to review the Piney Point situation that resulted in a unanimous consensus for the Gulf discharge plan. If we had heavy rains, if we had another Piney Point situation occur, would the Estuary Program support a similar decision and in reviewing that situation, what were the program's recommendations for ways to avoid a similar situation in the future?

Mr. Eckenrod. The request from EPA was whether or not the group of experts that we convened believed there was greater risk in disposing of a portion of that accumulated and partially treated wastewater offshore versus continuing to discharge into Tampa Bay. We consulted with marine experts from around the Gulf, experts in harmful algae blooms in particular, and the consensus of that group was that there was less risk in moving that water offshore than there was allowing that continued accumulation of that water in the stacks at Piney Point, or alternatively, discharging it into Tampa Bay. Both of those were options.

There was no--I think the groups that I have been working with and the Estuary Program has been working with, and that includes the Agency on Bay Management in Tampa Bay, we all, you know, share the belief that we need to take every reasonable measure possible to avoid occurrences like Piney Point in the future. And that is part of the reason I was interested in

participating in this hearing today, to share that concern and encourage this group to pursue, and EPA to actively pursue these beneficial uses of phosphogypsum to the extent that it can help reduce risk like Piney Point in the future.

Mr. Putnam. From your perspective, do you believe that the environmental risk associated with stacks is greater than the risk of dispersing the stacks throughout the State amongst the alternative uses that have been illustrated, is it a greater risk to leave them stacked up?

Mr. Eckenrod. Well, it is a difficult question for me to answer, not being an expert in radiation and obviously there are many people that have spoken today who do have that expertise. I can only say, Congressman, that based on the testimony I have heard, there is certainly expressed many potential uses of phosphogypsum that offer the hope that the risk would be--by making use of those opportunities, the risk could be reduced below what the current technology provides for; that is, stacking it.

Mr. Putnam. Dr. Sumner, do you wish to add anything to what we have heard in terms of the models that have been used and the work that you have done and others have done and this acceptability to the EPA?

Mr. Sumner. Mr. Chairman, I have been in this game for 45 years and I have had all the research work I have ever done reviewed by my peers, and I find it is an insult to hear that any of the research that I am accredited in my report or that I might have done myself is suspect. Scientists work according to given rules and our science is the best available.

So in my report, there is no fiction. This is the fact of the matter as we know it today. There might be some holes in it, we do not know, but those are facts. I want to say that first.

Second, I want to interject a little bit of common sense into this discussion here today, Mr. Chairman. In the old days, we used to use single super phosphate, which was composed of calcium dihydrogen phosphate and calcium sulfate, gypsum, in a 50/50 mix roughly, roughly 50/50. So in the old days, if the engineers had not got to us and decided we needed high analysis fertilizers to cut down on transportation costs, we would still be spreading single super phosphate all over the country. And if we did that at the rate that is recommended, and this would be the low rate that is recommended, at about 30 pounds per acre per year, we would be spreading 120 pounds of gypsum and that would be Florida gypsum full of radiation probably on every acre of agricultural soil, definitely east of the Mississippi and probably some distance west of the Mississippi. And we would have been doing that now for more than 100 years and we would have far exceeded the 2,700 pounds that the EPA has used and I venture to say right now that the EPA would not have had the temerity to ban single super phosphate.

Thank you, Mr. Chairman.

Mr. Putnam. Mr. Lloyd, your comments at this stage in the game?

Mr. Lloyd. I would like to correct one thing that was said. Ms. Cotsworth made the comment that the concentration was increased in phosphogypsum. The concentration of radioactivity is actually reduced in phosphogypsum.

I would like to receive the documentation that she had mentioned that says they had checked out building roads with 10 picocurie phosphogypsum. If that is in any of the BID documents, I cannot find it. Doug, were you ever able to find it, using 10 picocuries for road building?

Dr. Chambers. I did not see their analysis--I cannot recall seeing their analysis of 10 picocuries per gram.

Mr. Lloyd. So I would like to see that.

The one thing that might be interesting to you as a Congressman, in the 1989 rule, the public participation never discussed banning phosphogypsum. That part was not part of the discussion or the rule. And I would appreciate this easy-to-use guidance. We asked for it back in 1995. I would think 19 years is a long time to get it done.

Mr. Putnam. Ms. Cotsworth, could you provide to the subcommittee the background information, the studies on road building using to 10 picocurie per gram material for north Florida?

Ms. Cotsworth. Just a minor correction. I indicated that we did studies that suggested that a national generic permission for use as road building material was not supported in terms of risk. I do not believe I used the term 10 picocuries per gram in regard to that specific reference.

In the BID documents, as requested, the specific reference is to an investigator by the name of Roffler, Gamma radiation and radon flux from roads constructed with bases having phosphogypsum-bearing aggregate, from the University of Florida, 1987. And the information is contained, I believe, on pages 426 and 427. That is the information that the staff at that point used.

Mr. Putnam. Thank you.

The real crux of all this is that it is the opinion of--and I believe the adopted policy of at least this county that finding a viable economic use for these stacks is our goal. And the State of Florida has invested, through the Department of Education and with substantial support from the private sector, in the Florida Institute of Phosphate Research, as well as the other academic studies that have gone on, to find a use for this product.

I am hopeful that this hearing will have communicated to the EPA our interest in allowing research to go forward that would provide us some guidance for alternative use of this product. It has bubbled under the surface for years and has been something that people talk about when they drive down Highway 60 and they see them. But it has reached an important sense of urgency as a result of the events of last summer and the discharge that had to occur, that highlights the potential risk that storing these stacks poses. I think it is tragic that legitimate, accredited, highly thought of researchers have a difficult time interacting with their government and finding a way to share research that has the potential for public benefit. And that has transcended Republican administrations, Democrat administrations. It is a culture issue at EPA that has absolutely nothing to do with who is in charge, because the same people are in those offices in Atlanta and at the mid level and everything else that make these decisions.

So I would hope that as a result of this hearing, which may just be the second of several if need be, that we would facilitate a better information transfer, that we could have some objective, some goal line of knowing what the definition of a complete application is so that process can move forward and the people of Polk County, people of Florida and the potential new industries that could come from alternative uses and the potential savings that could accrue in terms of road building or land fill management would be able to have some guidance. And that guidance, that progress, has been lacking. And it has been, I think very frustrating for an awful lot of people.

So, you know, I would hope that we would get the information that we have requested, that we can facilitate the meetings that you have committed to and, frankly, I think expand it certainly to include my office and your water office, we will make that communication as well, because I think

something that has come forward today is that there clearly has to be a conflict of environmental goals between your water office and your air quality office when your water office is sent to respond to an emergency created by the concentration of phosphogypsum in stacks and the water that is held as a result of rainfall and everything else. So I think that is an important component to this as well. And I invite you to respond.

Ms. Cotsworth. I want to make this petition process work for both the agency and the petitioners. And I have made it a priority since I have become the office director to both clearly respond to and process the current petition that we have in-house, and to issue the guidance that petitioners have been crying for. I also believe that I personally have a reputation for being someone who deals honestly and openly and is accessible to members of the regulated community as well as the rest of the public. And I am interested in making sure that--the bottom line is that the decisions that we make are clear and transparent, but also publicly and technically and scientifically defensible.

So I will certainly be willing to work with your office and the other people at this table. I know science has progressed, there have been changes in the agency since 1989 and the 1992 regulations. There has also been culture changes within the agency. But I will be glad to work with the petitioners, your office, our fellow regulatory agencies and others in regard to this issue.

Mr. Putnam. Thank you very much.

How many other issues are in your portfolio that involve this type of history with a State-sponsored research laboratory who has been specifically charged with investigating the use of a product that you regulate and has that kind of 19-year tradition of trying to move this along. Is that a fairly common thing?

Ms. Cotsworth. No, it is fairly unique.

Mr. Putnam. In most agencies or departments, you would assume in life that when you have sort of a small universe of players and one of them has been around since day one and are legitimate, you know, they are not--you know, being in the constituent service business, we all understand that sometimes folks come to the table bearing more research and more facts and have the credentials to back those up. It would seem that a better relationship would have just naturally developed over time, knowing that there is a whole building out here full of laboratories working to do nothing but find a better use for phosphogypsum, and it just seems odd that it has degenerated into sort of an adversarial thing instead of really a committed partnership to find a better use.

I take you at your word and hope that today marks a turning point and a move toward progress toward working to resolve these issues.

I also just wanted to ask if there were, as part of the Clean Air Act reauthorization, if there were a legislative change that affected the regulation of phosphogypsum that would allow for the use in these instances--road beds and landfills as well as a couple of the other things that we talked about, the glass and the marine life--would you lay awake at night worried about public health and the impact that might have on the population?

Ms. Cotsworth. It is inappropriate for me to comment on the possibility of legislative changes. Again, we will be glad to work with you or whomever on the Hill in regard to technical evaluation, give you our best technical and scientific input for you to use in making your tough decisions relative to legislation and then we will implement them appropriately.

Mr. Putnam. Thank you.

Mr. Keaton, would you like to add anything?

Mr. Keaton. Well, I guess in listening to everything that has been said, I think one thing that maybe we ought to point out here is that the doses and the risks that we have been talking about are calculated. These are numbers and models that we use to work with. There is real risk involved with hazards with this material getting into the environment as far as a dam breaking or things along these lines. So there are risks there that have to be balanced and I guess the EPA and the people have to deal with that.

What we do, what we would welcome is that the unfettered research and development of these products and these techniques in using this material, we welcome them and would work to help do that.

Mr. Putnam. Thank you. Mr. Eckenrod.

Mr. Eckenrod. You may have heard me shudder a little bit at the discussion earlier about some of the potential marine uses of phosphogypsum. I think we do need to think very carefully, as we would about any potential uses on the environmental effects of those. But it looks to me like--and I go back to what Mike Lloyd said earlier--that in the past when FIPR has talked to EPA, it has been constructive, they have made progress. So to the extent that this hearing can help get that constructive dialog back on track, I think it will be very successful.

Mr. Putnam. Thank you very much. Mr. Lloyd. Dr. Sumner. Dr. Chambers.

Mr. Chambers. Just a very brief comment. I would like to correct something as well.

There was in fact a detailed radiological assessment submitted along with the petition and so someplace in EPA files, there is information on radioactivity and potential radiological risks associated with it.

Other than that, when we submitted these, we tried to write them in a form, we sat down and asked ourselves a question if we were EPA, what kind of information would we like. So it may not be quite right, but we did make an attempt to make it easy. So we are hoping that EPA considers the work that we did in submitting the application when they come up with their guidelines.

Thank you very much.

Mr. Putnam. Thank you. Dr. Shieh.

Mr. Shieh. I would like to make a final comment. It seems to me the whole process looks at the project as a full scale operation, but it is not. It is still just one study and the finding of that study will provide solutions for big scale application. So a lot of effort has been put to me, it seems not in the right direction--a lot of effort we are doing today may not be necessary. So I want to ask again, please do not treat this project as a full scale application request, this is just one study to demonstrate if this idea is feasible or not feasible.

Mr. Putnam. Especially the phase III request, right?

Mr. Shieh. Yes, yes, yes.

Mr. Putnam. Well, I want to thank all of our distinguished panelists for their contribution to our understanding of this issue and the potentially beneficial uses as well as the risks that have to be balanced in using phosphogypsum for purposes other than stacking. It is necessary to reconsider the calculations that determine the commercial product or waste, in my view. We have a number of studies that suggest that it would be advantageous to everyone as well as environmentally sustainable to revise the EPA ban of phosphogypsum in research and in industry.

Certainly as was the case in the event there are additional questions we did not have time for today, the record will remain open for 2 weeks for submitted questions and answers. I believe that the subcommittee has put forward a number of information requests that we expect to be answered promptly, and we certainly appreciate the efforts that everyone has put into this.

I would note also for the record that the Florida Institute of Phosphate Research is within walking distance of this facility and I suspect if we want to use this as an opportunity to put our panelists together, I believe Mr. Lloyd might answer this correctly--available for all of our panelists to huddle up and talk about exactly what some of the issues are and how we can resolve this and make the application complete and move forward in a thoughtful, science-based manner.

So with that, I want to thank the audience for attending as well, I think your interest certainly demonstrates community involvement and a community interest in seeing this move forward in a productive and fruitful way. And the subcommittee stands adjourned.

[Whereupon, at 1:19 p.m., the subcommittee was adjourned.]

[Additional information submitted for the hearing record follows:]

Review article

Environmental impacts of phosphogypsum

P.M. Rutherford, M.J. Dudas*, R.A. Samek

Department of Soil Science, University of Alberta, Edmonton, Alberta T6G 2E3, Canada

(Received 22 September 1992; accepted 26 May 1993)

Abstract

Phosphogypsum is an acidic by-product from the phosphate fertilizer industry. Large quantities are produced world-wide and it is estimated that by the year 2000 up to 280 million tonnes will be produced annually. Although phosphogypsum is mainly calcium sulfate dihydrate, it contains elevated levels of impurities which originate primarily from the source phosphate rock used in P fertilizer production. The main environmental concerns associated with phosphogypsum are: (i) movement of fluoride, sulfate, total dissolved solids, certain trace elements, and radionuclides from the U-238 decay series below phosphogypsum stacks into groundwater supplies; (ii) radon-222 exhalation which may pose a health risk to workers on the site or people living close to stacks; (iii) acidity; and (iv) radon-222 exhalation from soil into residential homes when agricultural land previously treated with phosphogypsum is converted to residential usage. In order to fully understand the environmental impact of phosphogypsum, it is necessary to understand the geochemical and hydrological processes that control the composition of phosphogypsum leachates and the attenuation of environmentally sensitive chemical species when these leachates enter soil environments. This article will review the chemistry of phosphogypsum and the environmental concerns associated with phosphogypsum that is stockpiled in waste repositories or is used as an agricultural soil amendment.

Key words: By-product gypsum; Radon; Natural-occurring radioactivity; Heavy metals; Fluoride; Waste management

1. Introduction

Phosphogypsum is an acidic by-product produced by the phosphate fertilizer industry during the production of phosphoric acid from phosphate rock. The by-product is composed mainly of gypsum and the phosphorus content is usually below 1%. Levels of fluoride, certain natural-occurring radionuclides and trace elements are relatively high and there is concern that the material may pose a negative impact on the environment. World-wide production of phosphogypsum was 120–150 million metric tonnes in 1980 (Carmichael, 1988) and it is estimated that if historic trends continue, production will increase to 220–280 mmt by the year 2000 (Ferguson, 1988). A study in 1981 showed that of the phosphogypsum produced, 14% is reprocessed, 58% is stored and 28% is dumped into water bodies (Carmichael, 1988). The objective of this review is to summarize the literature dealing with phosphogypsum, with emphasis on the chemistry of phosphogypsum and

ED_005285_00000596-00001

the concerns which may arise when phosphogypsum leachates come in contact with the terrestrial environment.

Large amounts of phosphogypsum are dumped, often into water supplies throughout the world. The Djorf Lasfar plant in Morocco pumps 25 000 tons/day of phosphogypsum into the Atlantic Ocean when operating at nominal capacity (Becker, 1989). Readers interested in the environmental consequences of dumping into water should consult articles by Becker (1989) and van der Heijde et al. (1988, 1990). Readers should refer to other reviews (Arman and Seals, 1990; Novikov, 1990) for more information on the possible utilization of phosphogypsum in engineering and chemical industries.

2. Phosphoric acid production

Phosphoric acid, which is used in phosphate fertilizer production, can be produced either by: (i) the electric furnace process, which uses electrical energy to produce elemental P as a first stage; or (ii) the wet process using sulfuric acid attack. Currently, the wet process accounts for over 90% of phosphoric acid production (Becker, 1989). Phosphate rock, which is composed mainly of apatite, is treated with concentrated sulfuric acid and water to produce gypsum, phosphoric acid and hydrogen fluoride. The most common process results in the production of calcium sulfate dihydrate:

$$Ca_{10}(PO_4)_6F_2 + 10H_2SO_4 + 20H_2O \rightarrow 10CaSO_4 \cdot 2H_2O + 6H_3PO_4 + 2HF$$

Once crystallized, the gypsum is separated from the liquid phase by filtration, mixed with water and sluiced to a disposal area or a holding area. The acidic process water is recycled. Hydrofluoric acid reacts with undissolved silicate impurities in phosphate rock to produce silicon tetrafluoride (SiF_4), which hydrolyzes to form fluorosilicic acid (H_2SiF_6). High temperatures produced during processing may allow the F acids to decompose forming gaseous SiF_4 and HF. These are usually recovered as fluorosilicic acid (H_2SiF_6) by absorption in water using scrubbers.

Phosphate rock is usually treated in a physical process called beneficiation, prior to acid treatment in order to concentrate the P content of the ore (Becker, 1989). Beneficiation often involves concentration by washing, screening and flotation (Roessler, 1979a). Calcination, the crushing of rock and heating to 910°C, may be required to reduce the organic content down to approximately 1% prior to acidulation (Norris, 1969; McClellan and Gremillion, 1980).

Approximately 5 tonnes of phosphogypsum are produced per tonne of phosphoric acid (P_2O_5). The degree of calcium sulfate hydration depends on the operating acid concentration and temperature (Witkamp and van Rosmalen, 1986), and may increase during transport and storage of the phosphogypsum. The dihydrate ($CaSO_4 \cdot 2H_2O$) phosphoric acid process, which is the most common (Yarnell, 1987), produces 28–30% acid. The hemihydrate process ($CaSO_4 \cdot 0.5H_2O$), relatively widely used in Europe, Japan and Africa, produces a purer phosphoric acid product with higher P_2O_5 concentration (Kouloheris, 1980). Various modifications to the hemihydrate process have been adopted by companies to produce acid concentrations between 32 and 52%. Details of various wet phosphoric acid processes are summarized by Becker (1989) and Kouloheris (1980).

2.1. Chemical and mineralogical composition of phosphate rock

Phosphate ore partly determines the nature of the phosphorus fertilizer and phosphogypsum. Phosphate ores are of sedimentary, or of igneous and metamorphic origin. Sedimentary phosphates, also known as phosphorites, represent about 85% of known phosphate rock (Habashi, 1980). The most easily mined deposits are from the great sedimentary basins which formed approximately 70 million years ago and are associated with matter from living organisms (Becker, 1989). Phosphate ores are subject to wide compositional variation and differences in quality. Apatite is the principle phosphate mineral in most phosphate deposits (Lehr and McClellan, 1972). Becker (1989) presents the chemical composition of phosphate rock concentrates from a variety of sources. Major components are CaO (29–54%), P_2O_5 (24–40%),

SiO_2 (0.1–14%), F (1.3–4.1%), CO_2 (0.2–7.3%), SO_3 (0.0–3.3%), Al_2O_3 (0.2–1.8%), Fe_2O_3 (0.1–2.6%), MgO (0.0–2.2%) and Na_2O (0.2–1.5%). Phosphorites contain approximately 10% quartz, 5% muscovite-illite, 2% organic matter, 1% dolomite-calcite, 1% iron oxide, and 1% other components (Gulbrandsen, 1967). The most common Fe-Al oxides and hydroxides identified in sedimentary phosphate rock are goethite, limonite, bauxite minerals and barbosalite (McClellan and Gremillion, 1980). Minor components include fluorite, zircon, tourmaline, montmorillonite, kaolinite, sphene and pyrite (Gulbrandsen, 1967). Other accessory minerals include titanium minerals such as rutile, ilmenite, anatase and perovskite (McClellan and Gremillion, 1980).

Francolite is the amorphous form of apatite in sedimentary phosphorites. Igneous fluorapatite has the formula $Ca_5(PO_4)_3F$ but francolite exhibits more elemental substitutions (Osmond et al., 1985; McClellan and Lehr, 1969). Apatite varies greatly in physical, chemical and crystal properties (Lehr and McClellan, 1972). The most common apatites are carbonate apatites with isomorphous substitution of carbonate and F (CO_3F groups) for phosphate and minor substitution of Ca with Na and Mg atoms (McClellan and Lehr, 1969; Lindsay et al., 1989).

The enrichment of trace elements in phosphorites is best compared relative to shale, a common marine rock and the most common surficial rock (Altschuler, 1980). Compared to shale, the trace elements enriched in the average phosphorite are Cd (60×), U (30×), Ag (30×), Y (10×), Se (8×), Yb (5×), Mo (4×), La (4×) and Sr, Pb and Zn (each 2×). The rare earth elements, except for Ce, also exhibit enrichment relative to shale (Altschuler, 1980). The elements depleted are Li (13×), Ti (7×), Hg (7×), B (6×), Ga (5×), Co (3×) and Sn and Zr (each 2×) (Altschuler, 1980). Tooms et al. (1969) compared the elemental composition of phosphates from a variety of sources and concluded that relative to average crustal abundances, As, Cr, and Sn were enriched and Ba, Cu, Mn and Ni were depleted. Gold and Th concentrations appear to be similar in phosphorites relative to shales and Bi is enriched (Altschuler, 1980). Enrichment of Bi may be due to substitution in apatite because the ionic radius of the Bi^{3+} ion (0.093 nm) is close to Ca^{2+} (0.099 nm) (Altschuler, 1980).

Enrichments vary between phosphorite formations. For example, relative to shale the following trace elements are enriched in the Phosphoria formation: Ag (60×), Mo (50×), Se (20×), Nd (10×), Cr (10×), As (4×), Cu (2×) and V (2×). The following elements are depleted: Zr (6×), Mn (30×), Ba (6×) and Pb (2×) (Gulbrandsen, 1966).

Some of the elements enriched in phosphorites are known, or are theorized on crystallographic spacings, to substitute for Ca in apatite. These elements are Cd, U, Sr, Pb, Zn, Y and the lanthanides (Altschuler, 1980). Substitutions of Na^+ for Ca^{2+} and SiO_4^{4-} for PO_4^{3-} maintain electrical neutrality. Small quantities of CO_3^{2-}, VO_4^{3-}, AsO_4^{3-} and SO_4^{2-} may substitute for PO_4^{3-} in the crystal structure (Sweeney and Windham, 1979). Silver, Se and Mo are often associated with organic matter and enrichment may be due to complexation or adsorption with organic materials, similar to reactions found for As, Cd, Cu, Ni, Sb, V and Zn (Krauskopf, 1955; Gulbrandsen, 1966), or as metallic sulfide precipitates formed under reduced conditions (Altschuler, 1980). The elements depleted in phosphorite usually either occur in relatively stable and insoluble minerals, or they possess cationic or anionic configurations which cannot fit into the apatite crystal structure.

2.2. Natural radioactivity in phosphate rock

Many phosphate ores are high in natural radioactivity relative to shale. The radioactivity originates mainly from the U-238 and Th-232 decay series (see Figs. 1 and 2) and varies with the type of phosphate rock. Uranium-235 is not as prevalent in nature as U-238 and consequently radiation originating from this decay series is not considered to be a concern. Sedimentary phosphates typically contain high U concentration and low Th concentration, but igneous phosphates typically contain low concentrations of U and an appreciable amount of Th and rare earth elements (Habashi, 1980). Radionuclide concentration in the beneficiated rock is typically 100–300% of the concentration of the unprocessed rock (Roessler 1979a). Metzger et al. (1980) reported that the specific activities of U and Th-230, and the con-

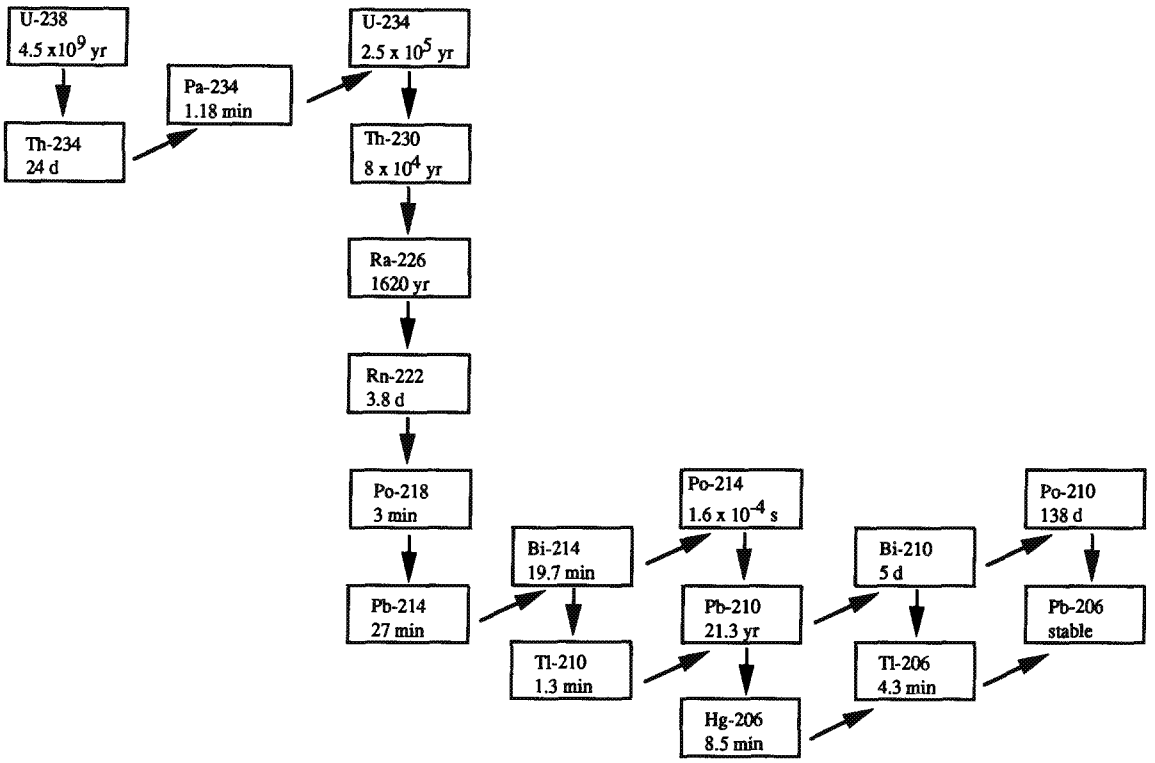

Fig. 1. Uranium-238 decay series. Diagonal arrows designate beta-decay and vertical arrows designate alpha-decay. Radionuclide half-lives are included.

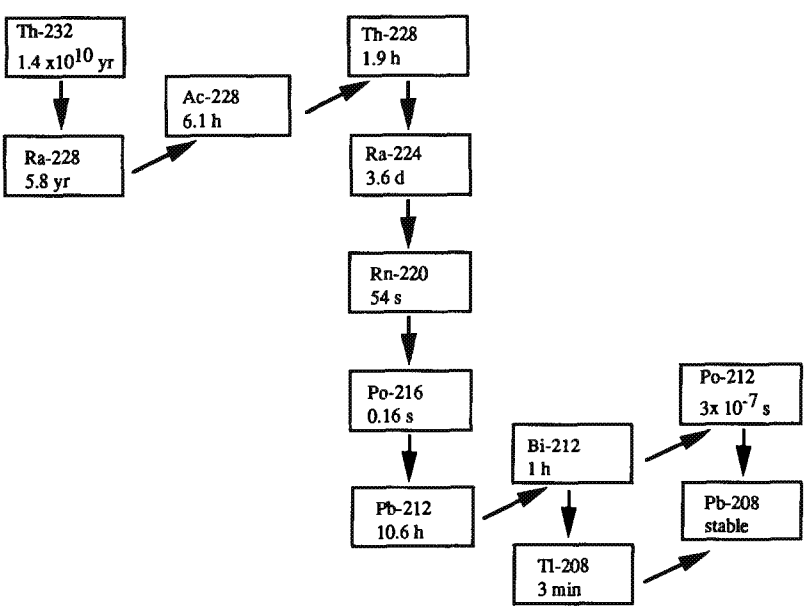

Fig. 2. Thorium-232 decay series. Diagonal arrows designate beta-decay and vertical arrows designate alpha-decay. Radionuclide half-lives are included.

centrations of Al, Cu, Mg, Na, Ti and Zn, were found to increase with decreasing particle size of beneficiated ore.

Uranium commonly exists in two oxidation states, U(IV) and U(VI). Most researchers agree that U as U(IV) replaces Ca in the apatite structure; however, some U(VI) may be adsorbed as the uranyl ion (UO_2^{2+}) onto apatite crystal surfaces (Hurst and Arnold, 1980; Burnett et al., 1988). Uranium (IV) may also be adsorbed or exist as a chemically-complexed phase on clay minerals and organics (Upchurch et al., 1991). In Florida phosphate rocks, U(IV) represents 40–90% of the 10–200 $\mu g\ g^{-1}$ of U (Lindeken, 1980). Menzel (1968) summarized the contents of U, Ra and Th in phosphate rocks from different sources around the world. Uranium content ranged from 3 $\mu g\ g^{-1}$ in ore from Chile and Ecuador islands to 399 $\mu g\ g^{-1}$ in ore from South Carolina. Typical soil values for U are approximately 2.7 $\mu g\ g^{-1}$ (Sposito, 1989).

Thorium exists in the +4 state in nature. Thorium (IV) probably substitutes for Ca in the apatite structure due to the similarity of the two ionic radii (IR = 0.102 vs. IR = 0.099 nm, respectively), although thorium may also concentrate in other compounds because it readily coprecipitates with oxidate minerals like Fe and Mn oxides. Levels of radionuclides from the Th-232 decay series are usually low in most sedimentary phosphate ores (Metzger et al., 1980).

Radium-226 is the most abundant Ra isotope in sedimentary phosphate ores. Radium-228 is present at very low concentrations because it is a product of the Th-232 decay series (Osmond et al., 1985). Menzel (1968) found Ra levels to range from undetectable in western European phosphates to $133 \times 10^{-6}\ \mu g\ g^{-1}$ ore from South Carolina. Roessler et al. (1979a) found U-238 and Ra-226 activities in Florida phosphate ore to be in approximate secular equilibrium and averaged 0.3 Bq g^{-1} in north Florida and 1.4 Bq g^{-1} in central Florida. Due to the chemical and crystallophysical properties of Ra-226 the radionuclide probably does not occupy regular lattice positions within U-bearing materials (Burnett et al., 1988). Where as U(IV) (IR = 0.097 nm) often substitutes for Ca (IR = 0.099 nm) in apatite due to the similarity of size (Hurst and Arnold, 1980), Ra has an ionic radius of approximately 0.152 nm (Ames and Rai, 1978; Vdovenko and Dubasov, 1975), which is too large for the isomorphous replacement of Ca. Likely, Ra in phosphorite is co-precipitated with Ba and/or Sr as a sulfate compound.

A review of world-wide data on natural radioactivity in phosphate rock, products and by-products was presented in the 1977 report on the United Nations Scientific Committee of the Effects of Atomic Radiation (UNSCEAR, 1977). Guimond (1978) also reviewed the natural radioactivity associated with the phosphate industry.

3. Characteristics of phosphogypsum

3.1. Physical characteristics

Phosphogypsum has physical properties similar to natural gypsum. Particle density ranges between 2.27 and 2.40 g cm^{-3} (SENES, 1987). Bulk density within phosphogypsum stacks has been reported to range between 0.9 and 1.7 g cm^{-3} (Vick, 1977; Keren and Shainberg, 1981; May and Sweeney, 1984a). Phosphogypsum generally has a large proportion of medium to fine-grained particles. May and Sweeney (1984a) reported medium sized particles (0.250–0.045 mm diameter) to account for 36–60% of the mass of seven phosphogypsum samples. Fine particles (<0.045 mm diameter) accounted for 2–49% of the mass. SENES (1987) reported 30% of the phosphogypsum obtained from a stack in Dunnville, Ontario to be of fine size or smaller, while 50% of the phosphogypsum was of fine size or smaller at another stack at Calgary, Alberta. The fine particle size of phosphogypsum results in a rapid dissolution rate relative to mined, natural gypsum (Keren and Shainberg, 1981). Harvie et al. (1984) estimated the solubility product for gypsum to be 2.63×10^{-5} at 25°C. Vertical hydraulic conductivity of phosphogypsum has been reported to range between 1×10^{-3} and 2×10^{-5} cm s^{-1} (SENES, 1987).

The free water content of phosphogypsum may vary greatly depending on how long the phosphogypsum has been allowed to drain after sluicing to the stack, and on local meterological conditions. The free water content of phosphogypsum is often

determined by drying at 65°C for 5 h. This method may result in the loss of some water of hydration when drying occurs above 60°C. Drying at a lower temperature may be very time consuming; consequently Averitt and Gliksman (1990) recommend drying at 50°C for 5 h under vacuum.

Phosphoric acid process conditions influence the crystal morphology of phosphogypsum. It is important that the gypsum crystals produced do not have surface-to-volume ratios which are so high that they impede phosphoric acid flow during filtration (Becker, 1989). Crystal shape and size distribution determine the surface-to-volume ratio and filter cake porosity (Becker, 1989). Common gypsum shapes include needles, small thin lozenges, rhombic and X-shaped swallowtail twins, flat table-like, clusters and thick rhombic types (Becker, 1989). Ball-like clusters have the minimal surface-to-volume ratio and produce the most rapid acid flow rates. The most common shape is a table-like elongated crystal, with dimension ratios of 16:4:1 (Becker, 1989). May and Sweeney (1984a) reported that Florida phosphogypsum exhibited monoclinic crystals which were tabular and diamond-shaped. This was also found by Luther et al. 1993. Larger crystals had sides ranging between 15 and 30 μm, a thickness of 3–5 μm and a length of 20–40 μm. Solid needle shapes, hollow four-sided tubular shapes and thin flakes were also observed.

The factors which control the shape and size of the gypsum crystals formed in the reaction slurry are: (1) the type of phosphate rock; (2) phosphate rock particle size; (3) concentration of phosphoric acid; (4) solids content in the slurry; (5) excess sulfuric acid in the slurry; (6) impurities in the phosphate rock; (7) temperature; and (8) the reaction system, feed-to-volume ratios, agitation, and recirculation (Becker, 1989).

3.2. Chemical and mineralogical composition

The chemical and mineralogical characteristics of phosphogypsum depend on the nature of the phosphate ore, the type of wet process used, the efficiency of plant operation, the age of the stockpile, and any contaminants which may be introduced into the phosphogypsum at the production plant (Arman and Seals, 1990). Calcium and SO_4^{-2} dominate the composition of phosphogypsum because it is approximately >90% gypsum (Berish, 1990). Phosphogypsum is acidic due to residual phosphoric acid, sulfuric acid and fluoride acids contained within the porosity. May and Sweeney (1984a) found the pH of extracts from Florida phosphogypsum to range between 2.1 and 5.5. The pH of aged and leached phosphogypsum may approach neutrality (SENES, 1987). The acidic nature of fresh phosphogypsum may keep trace elements dissolved from phosphate rock in a potentially mobile state.

Although phosphogypsum solids are mainly gypsum, many impurities are present. These include quartz, fluorides, phosphates, organic matter and minerals of Al and Fe. Using X-ray diffraction, May and Sweeney (1984a) found α-quartz to make up approximately 5% of Florida phosphogypsum. May and Sweeney (1984b) conducted X-ray analyses on the evaporites of water-soluble material from gypsum and found only gypsum and hemihydrate. The sensitivity of the analysis was not sufficient to identify trace element compounds. Luther et al. (1993) found crystalline or amorphous materials among the matrix of well-formed gypsum crystals using SEM-EDX. These minerals were dominated by Si and/or P, combined in some cases with significant amounts of Al, Na, K, Ca and/or S. The Si was attributed to α-quartz, or to feldspars in the presence of Al and Na or K. The P was attributed to residual phosphate rock. Some samples contained as much as 10% SiO_2 and 1.6% P_2O_5. Silica is sometimes added to the liquor in phosphoric acid production to assist in the crystallization process (Beretka, 1990). Silica may also originate from sand present in process water supplies.

Major elemental composition of phosphogypsum varies according to the type of wet phosphoric acid process used (Table 1). Minor element composition may vary greatly depending on the source of the phosphate rock (Table 2). Luther et al. (1993), in part, studied the elemental composition of Alberta phosphogypsum originating from western Idaho rock and compared the results with literature values for terrestrial materials (Table 2 and 3). Relative to shale, phosphogypsum was elevated in total content of Ag, Au, Cd, Se, Sr, and some of the light rare earth elements and Y. Phospho-

Table 1
Typical major element composition (%) for phosphogypsum produced under different processes[a]

Component	Dihydrate	Hemihydrate	Hemi-dihydrate

gypsum from central Florida had greater As, Sb and Mo content than the Alberta phosphogypsum but had lower concentrations of Ag, Ba, Cd and Sr. In terms of total concentrations, May and Sweeney (1984a) said phosphogypsum could not be classified as a toxic waste because it was neither corrosive (pH was >2 and <12.5) and because the average total elemental concentration of elements classified as toxic by the E.P.A. (As, Ba, Cd, Cr, Pb, Hg, Se, and Ag) were less than the E.P.A. allowable toxic elemental criteria for toxic hazardous waste (Federal Register, 1980).

Levels of Y, Zr, Cu, Ba, and Ni in South African phosphogypsum were much greater than central Florida levels (Table 2). Tunisian phosphogypsum was reported to contain very high levels of Cd, Hg and Zn. Compared to Quebec standards for the classification of contaminated soil, the phosphogypsum was slightly contaminated with Zn and Mo, but highly contaminated with Cd and Hg (Rouis and Bensalah, 1990).

Table 4
Trace element transfer (%) from U.S. phosphate rock into phosphogypsum[a]

Element	Percent transfer
Cd	30–54
Cu	64–100
Zn	20–49
Cr	3–26
V	1–100

[a]Adapted from Becker (1989).

Berish (1990) identified acidic process water, fluoride, radionuclides and heavy metals as possible contaminants of concern in phosphogypsum. Table 4 shows the percent transfer of trace elements from phosphate rock to phosphogypsum during the wet phosphoric acid process. Although the dihydrate process has the advantages of lower capital outlay, lower production costs, the ability of processing varying grades of phosphate rock and the capability of producing an acid from which U can be extracted (Kouloheris, 1980), the process has the major disadvantage of producing a gypsum with the most impurities. The impurities are mainly fluorine compounds (1.5–2.5%) and phosphate compounds (0.82% by wt.) (Schroeder and Gorecki, 1980). Filter cakes from the dihydrate process may contain as much as 0.5–1.0% P_2O_5. Impurities in typical hemihydrate are still relatively high and there is no method to extract U from the acid of this process (Kouloheris, 1980). The hemi-dihydrate process produces a relatively clean phosphogypsum filter cake (Table 1).

The form of major and trace elements in a solid can be attributed to a number of processes including precipitation in an essentially pure mineral

phase, fluid inclusions, co-precipitation, solid solution formation and adsorption on the surface of organic or mineral components (Luther and Dudas, 1993). Free phosphoric acid, unreacted phosphates, sodium hexafluorosilicate, sodium sulfate, fluorosilicic acid and organic compounds may adhere to the surface of gypsum crystals. Elements which substitute into the gypsum structure include Cd (van der Sluis et al., 1986; Witkamp and van Rosmalen, 1988), Sr, Mg, Na, K and Cl (Kushnir, 1980) and Se (Neal, 1990). Dicalcium phosphate, monosodium sulfate and fluorophosphates may also substitute into the crystal structure of gypsum crystals. Fluorite and fluorapatite may be the potential solubility controlling solids for F in phosphogypsum (Murray and Lewis, 1985; Jenne et al., 1980). A solid solution exists between gypsum and dicalcium phosphate because HPO_4^{2-} ions replace SO_4^{2-} ions in the gypsum lattice structure (Goers, 1980; Olmez and Erdem, 1989). Substitution of phosphate into the gypsum crystal during acidulation is reduced with higher SO_4^{2-} concentrations, longer phosphate attack times, higher reaction temperatures and high percent solids (Goers, 1980). Silicon probably exists as amorphous SiO_2, quartz or in SiO_2-containing minerals (Lindsay, 1979; Rai et al., 1987).

Fluorapatite contains up to 1% by mass of rare earth elements (REE) (Berdonosova et al., 1989). Phosphogypsum may be composed of 0.5% lanthanide oxides (Kijkowska et al., 1989). The REE are members of Group IIIA in the periodic table and are also referred to as the lanthanide series. They have similar chemical properties because all have a relatively stable +3 oxidation state. Yttrium is not a REE but it shares a similar chemistry with REE and is therefore often discussed with members of the REE (Henderson, 1984). Sixty to 80% of the REE present in phosphate rock may be partitioned into the phosphogypsum (dihydrate or hemihydrate) during the production of phosphoric acid (Andrianov et al., 1976; Berdonosova et al., 1989). However, there is evidence that heavy REE (Gd to Lu) may be preferentially partitioned into phosphoric acid compared to the light REE (La to Sm) during the wet phosphoric acid process (May and Sweeney, 1984b). Elements such as Ce^{3+} in the presence of Na^+ form a solid solution with hemihydrate during crystallization [$NaCe(SO_4)_2 \cdot H_2O + CePO_4 \cdot 0.5H_2O$] – $CaSO_4 \cdot 0.5H_2O$ (Bushuev et al., 1988). This stabilizes the hemihydrate sulfate structure and slows down the recrystallization of dihydrate sulfate during the hemi-dihydrate process (Bushuev et al., 1988).

It is not known what chemical forms many of the trace elements take in phosphogypsum, although sulfate and phosphate minerals are likely under aerobic, acidic conditions (Luther and Dudas, 1993). Possible solubility controlling solids for trace elements in phosphogypsum will be discussed in a later section.

3.3. Radionuclides and their geochemistry

Phosphogypsum is enriched in radioactivity relative to most geological and soil materials because it is derived from phosphate rock, which contains relatively high levels of naturally-occurring radionuclides. The source of radioactivity comes from two decay series originating from the two parent radionuclides, U-238 and Th-232 (Figs. 1 and 2). The U-235 or Actinium decay series also exists in nature but the shorter half-life of U-235 (7.13×10^8 years), compared to U-238 (4.51×10^9 years) and Th-232 (1.39×10^{10} years), has reduced the abundance of this U isotope over the millennia to 0.72% of total U. Thorium content in sedimentary phosphate ores is usually low (Menzel, 1968; Metzger et al., 1980) and is not considered an environmental concern except in igneous phosphate rock deposits.

In undisturbed natural deposits, the members of the U-238 decay series are in approximate radioactive equilibrium; however, some Rn-222 gas may diffuse out of the material, thereby reducing the activity of radionuclides which follow Rn-222 in the decay series. Beneficiation is a physical process which does not appreciably disrupt radioactive equilibrium but increases the radioactivity of the concentrated rock by up to 400% over the non-processed matrix (Roessler et al. 1979a; Lisachenko et al., 1987). During the wet phosphoric acid process, the radioactive equilibrium within the phosphate rock is disrupted and the radionuclides are partitioned into various phases according to their solubility (Roessler et al., 1979a; Lardinoye

et al., 1982). Uranium, Th and Pb-210 distribute primarily into the phosphoric acid while most of the Ra-226 and Po-210 partition into the phosphogypsum. Hurst and Arnold (1982) reported that 60% of the Ra-226 and 99% of the Po-210 appear in the gypsum.

Reported radionuclide activities in phosphogypsum are presented in Table 5. Radium-226 activity is usually the largest source of radioactivity in phosphogypsum although some authors have also reported high activities of U-234, U-238 and Po-210. The highest Ra-226 activities have been

Table 5
Summary of reported radionuclide activities in phosphogypsum

Location of phosphogypsum	Phosphate rock origin	Radionuclide	Mean activity (Bq kg^{-1})	Reference
Alberta	Idaho	Ra-226	890	Luther et al., 1993
		Th-228	5.8	Luther et al., 1993
Australia	numerous	Ra-226	500	Beretka, 1990
			451	Beretka and Mathew, 1985

[a]Range.
[b]Active stacks only.
[c]Estimated assuming Ra-226 and Po-210 in phosphate rock were in equilibrium and 99% of Po-210 was partitioned into phosphogypsum during chemical processing.
[d]Estimated assuming equilibrium between Ra-226 and Bi-214, and between Ra-228 and Ac-228.

reported in phosphogypsum originating from central Florida rock, although phosphogypsum originating from Idaho or Syrian rock may be high as well. Generally, Th radionuclides have lower specific activities than Ra-226. Phosphogypsum produced from igneous rock phosphate may have Th-232 activities which exceed those of Ra-226.

Radium-226 content in phosphogypsum exceeds levels found in fly ash and soils, however, Th-228 content is generally less in phosphogypsum than fly ash or soil. Fly ash samples from coal combustion contain approximately 100 Bq kg^{-1} of Ra-226 (Coles et al., 1978; Kobal et al., 1990). Soil Ra-226 activity is typically less than 50 Bq kg^{-1} (Myrick et al., 1983; Kiss et al., 1988; Berish, 1990), although soil formed on high U containing parent materials may be more than 50-fold greater than this (Michel, 1987). Coles et al. (1978) reported Th-228 in fly ash to be 6–20 Bq kg^{-1}. Kiss et al. (1988) determined Th-232 and its daughter radionuclides to have an activity of 24 Bq kg^{-1} in Saskatchewan soils.

The specific activity of various radionuclides in phosphogypsum has been well reported; however, radionuclide geochemistry in phosphogypsum has not received much attention. The geochemistry of the radionuclides present in geological materials such as phosphate rock has been summarized in several publications (Ames and Rai, 1978; Osmond et al., 1985; Burnett et al., 1988; Upchurch et al., 1991).

Natural radioactive decay can affect the chemical behavior of radionuclides. For example, alpha recoil can break chemical bonds, move the recoiled atom to a different position in a solid and may damage crystal structures (Michel, 1987). This may have an effect on the activity of solids, especially ones of colloidal size, resulting in activities which exceed one (Upchurch et al., 1991). Biological processes can have an effect on radionuclide behavior. Birch and Bachofen (1990) review the effect of microbiologically derived complexing agents on radionuclide mobility. Microbially produced organic compounds have been found to increase the solubility of some radionuclides, such as U.

Uranium. The three naturally occurring isotopes U-234, U-235 and U-238 have average percent abundances of 0.0056, 0.72 and 99.27%, respectively, in the environment (Ames and Rai, 1978). The element is polyvalent and has complex solubility relationships depending on redox potential. Common oxidation states are +3, +4, +5 and +6, although the +4 and +6 states are the most stable (Ames and Rai, 1978).

Small amounts of U are normally contained within phosphogypsum. Most U from phosphate rock is partitioned into the phosphoric acid during the acidulation process (Roessler et al., 1979a; Hurst and Arnold, 1980); however, the partitioning is affected by redox conditions and the presence of other ions. Organic compounds in the processed phosphate rock tend to increase the U content of phosphogypsum (Gorecka and Gorecki, 1984). Uranium dissolution from phosphate rock is greater when acidulation is carried out under oxidizing conditions. Losses to the gypsum filter cake occur when unreacted rock particles are coated with gypsum or when U is substituted into the crystal lattice of the gypsum (Hurst and Arnold, 1980). Excess sulfate and fluoride may enhance the partitioning of U into the gypsum crystal. The U(IV) present in the crystal lattice of the apatite, and that formed by reduction of U(VI) by Fe(II) during acidulation, is trapped within the crystal lattice of the calcium sulfate crystals as they grow (Hurst and Arnold, 1980) because U(IV) and Ca^{2+} have very similar ionic radii (0.097 and 0.099 nm, respectively) (Gorecka and Gorecki, 1984). Thus, the presence of a large amount of Fe^{2+} may result in the transfer of as much as 80% of the U from the phosphate rock into the phosphogypsum. Uranium tends to concentrate in very small phosphogypsum particles (Gorecka and Gorecki, 1984). Under reduced conditions there is a greater transfer of U to phosphogypsum during processing. In contrast, 90–95% of U remains in the liquid phase under oxidizing conditions and in the presence of HNO_3. Small amounts of U may be present in phosphogypsum in the form of uranyl ion (UO_2^{2+}) contained within the residual phosphoric acid which remains after filtration and sluicing to the stack. Uranium (VI) may adsorb on the surface of gypsum as UO_2HPO_4 or UO_2^{2+} may substitute for two Ca^{2+} ions on the surface of the crystal lattice (Gorecka and Gorecki, 1984).

The U content of phosphogypsum also depends on the type of wet phosphoric acid process used. The dihydrate method results in a U content of 5–25 $\mu g\ g^{-1}$ but the hemihydrate process results in a content of 5–100 $\mu g\ g^{-1}$. This difference is due to several factors. The hemihydrate has a hexagonal instead of a monoclinic unit cell structure (Turk and Bounini, 1984) and forms agglomerates and clusters which more easily accommodate U into the crystal structure (Gorecka and Gorecki, 1984). Higher temperatures and higher phosphate concentration also favor coordination into the hemihydrate.

The chemical behavior of U is affected by pH and redox conditions. Under reduced conditions and pH below 3–4, the uranous (U^{4+}) ion forms complexes with fluoride. At higher pH, uranous-hydroxy complexes form. The solubility of U(IV) species are low, but U(VI) species may be quite soluble and mobile. At pH below 5 uranyl ion (UO_2^{2+}) and uranyl fluoride dominate. Between pH 4 and 7.5 $UO_2(HPO_4)_2^{2+}$ becomes prevalent. Uranyl di- and tri-carbonate species become prevalent at higher pH. Minimum solubility of uranyl minerals occurs between pH 5 and 8.5 and sorption occurs in decreasing order to organics, ferric hydroxides, Mn- and Ti-oxyhydroxides, and clays (Osmond et al., 1985; Upchurch et al., 1991).

The distribution of U radioisotopes in the environment is affected by the radioactive decay process. As U-238 forms Th-234 alpha recoil results in some of the daughter Th-234 atoms to be ejected from the mineral crystals into pore water or air. Thus this leads to a greater enrichment of U-234, the decay daughter of Th-234, in groundwater relative to U-238 (Upchurch et al., 1991).

Radium. Radium-226 is a major source of radioactivity in phosphogypsum. This radionuclide is formed by alpha decay of Th-230 within the U-238 decay series. Radium-228 is the second most abundant Ra isotope but it is quite rare in phosphogypsum because it is formed within the Th-232 decay series which is not abundant in marine sediments.

Radium belongs to the alkaline earth elements and therefore is divalent and has similar properties to Ca, Sr and Ba. Consequently, Ra-226 is an environmental concern because it follows similar biological pathways as Ca (Roessler, 1980). Between 70 and 90% of the Ra in the body is contained within bone (UNSCEAR, 1977).

Ra-226 probably does not co-crystallize with calcium sulfate dihydrate during phosphoric acid production because: (i) radium sulfate is very insoluble compared to calcium sulfate dihydrate, therefore almost all radium sulfate will be precipitated before the gypsum begins to precipitate; (ii) the ionic radii of Ra (IR = 0.152 nm) and Ca (IR = 0.099 nm) are so different that isomorphous substitution is unlikely; and (iii) radium sulfate (along with barium sulfate) crystallize in the rhombohedral system while calcium sulfate dihydrate crystallizes in the monoclinic system. There is a greater chance of co-precipitation of Ra-226 in the calcium sulfate hemihydrate system than with the dihydrate system because the former crystallizes in a rhombohedric system (Moisset, 1980). May and Sweeney (1984a), Beretka and Mathew (1985) and Moisset (1990) have reported that most Ra-226 in phosphogypsum is associated with fine phosphogypsum grains. The fact that Ra-226 is more closely associated with the finer hemihydrate particles than the larger dihydrate particles is the basis of procedures designed to lower the radioactivity of phosphogypsum (Palmer and Gaynor, 1984; Moisset, 1990).

It has been known for a long time that Ra and Ba co-precipitate together as sulfates (Doerner and Hoskins, 1924). The solubility product constants (25°C) for radium sulfate and barium sulfate are $10^{-10.4}$ and 10^{-10}, respectively (Sillen and Martell, 1964; Gilkeson et al., 1983). The ionic radius of Ra^{2+} is 0.152 nm, while that for Ba^{2+} is 0.143 nm (Ames and Rai, 1978). In phosphogypsum, high Ca and low pH probably result in the solubility of solid solutions dominating the pore water chemistry of Ra because adsorption is negligible under these conditions (Langmuir and Melchoir, 1985). There is evidence that nucleation of Ra sulfate may be inhibited if Ba is not present (Gilkeson et al., 1983 cited by Upchurch et al., 1991). Moisset (1980, 1988, 1990) reported that Ca, Sr, and Ba co-precipitate into small spheres which exist individually or attached to the surface of calcium sulfate crystals. Langmuir and Melchoir (1985) found brines undersaturated by 5–6 orders of

magnitude with respect to pure $RaSO_4$. The Ra-226 concentration in the brine was probably controlled by the solubility of Ra in trace solid solutions with Sr and Ba. Sebesta et al. (1981) determined the predominant particulate form of Ra and Ba in uranium waste waters to be $Ba(Ra)SO_4$.

Not all Ra-226 in phosphogypsum originates from precipitation of sulfate compounds during the wet phosphoric process. Some Ra-226 in phosphogypsum may also originate from phosphate rock particles which have survived the sulfuric acid attack.

Even though Ra is considered to be relatively immobile there are some instances where high levels have been found in groundwater systems (SENES, 1987). Radium may form a soluble sulfate species such as the neutral $RaSO_4^o$ ion pair

(Upchurch et al., 1991). However, of the alkaline earth metals Ra shows the least tendency to form complexes (Ames and Rai, 1978). Until water becomes saturated with $RaSO_4$ and precipitation occurs, $RaSO_4^o$ complexes may be a major means of transport in groundwater systems (Upchurch et al., 1991).

Radium exists only as a divalent cation and is not directly affected by redox reactions; however, bacterially mediated redox reactions can indirectly solubilize heavy metals and radionuclides such as Ra-226 from (Ba, Ra) sulfate sludges. Thus anaerobic conditions may greatly increase the mobility of Ra-226 in the environment. Fedorak et al. (1986) studied the effect of sulfate reducing bacteria on release of Ra-226 from (Ba, Ra) SO_4 uranium mine sludges. They found approximately 400 Bq l^{-1} of dissolved Ra-226 in anaerobic uranium mine waste during laboratory batch incubations when high levels of lactate were added to the samples. The fact that Ra-226 release was increased by three orders of magnitude after carbon supplementation was considered to be of great practical significance (Huck and John, 1989). The U.S. drinking water standard for Ra-226 plus Ra-228 is 0.19 Bq l^{-1}. The Canadian drinking water guideline for Ra-226 is 1 Bq l^{-1} (Table 6).

The geochemical nature of groundwater influences Ra-226 concentrations. The leachability and retention of Ra-226 in groundwater may be enhanced by a solution of high ionic strength, such as groundwater with high total dissolved solids (Kaufman and Bliss, 1977; Burnett et al., 1988). Under these conditions high concentrations of other ions may out-compete Ra-226 for adsorption sites, thereby allowing more Ra to remain in solution.

Radon. There are 27 known isotopes of Rn gas, but only Rn-222 is produced in significant amounts by phosphogypsum made from sedimentary phosphorites. Radon-222 forms from the alpha decay of Ra-226. The radioactive gas has a relatively short half-life, 3.82 days, and forms Po-218 by alpha decay. Radon-222 is an inert, noble gas which is an environmental concern because it can be highly mobile and eventually decays to form two relatively long-lived radioactive daughters, Pb-210 and Po-210. The gas is soluble in water (partition coefficient = 0.35; Conc. in water/conc. in air at 10°C), and solubility increases with decreases in temperature. Solubility in organic liquids may be several orders of magnitude greater than in water (Cothern, 1987).

Not all the Rn-222 atoms formed from Ra-226 decay are released from mineral structures. Emanation is the process whereby Rn is released from the crystal structure. The emanation coefficient is the number of Rn-222 atoms which escape from the solid phase divided by the total number of Rn-222 atoms which form from the decay of Ra-226. Emanation coefficients for Rn-222 in crystals of apatite, monazite and uraninite have been measured to range between 0.5% and 25% (Rama and Moore, 1984). Phosphogypsum typically has an emanation coefficient of approximately 15% (Roessler et al., 1979b; Pensko et al., 1980; Ackers et al., 1985). Once Rn-222 has been released from the crystal structure it is free to diffuse through the pore spaces of the Ra-226 bearing material and reach the atmosphere. The exhalation rate is the flux density of Rn-222 gas entering the atmosphere from the surface of a Ra-226 bearing material (Bq m^{-2} s^{-1}) (SENES, 1987). The factors which determine the exhalation rate of Rn-222 from a source such as phosphogypsum are the Ra-226 content and its distribution, the emanation coefficient, atmospheric pressure, and the diffusion coefficient for radon. The diffusion coefficient will vary greatly depending on temperature and moisture levels (Windham and Horton, 1980). Cracks and crusts on the surface of phosphogypsum will greatly influence exhalation rates.

As Ra-226 forms Rn-222 a high speed alpha particle is ejected from the nucleus, carrying most of the excess energy produced during the radioactive decay. The newly formed Rn-222 atom recoils in the opposite direction with a kinetic energy which is 104–105 times greater than typical bond energies (Michel, 1987). As a result, the recoiled Rn-222 atom can move within mineral structure up to a distance of 70 nm (Tanner, 1964, 1980). If the mineral surface is present within this distance the Rn-222 atom may escape the crystal and be free to enter pore air or pore water. Thus, the amount of Rn-222 which is potentially available for release from a mineral is in part related to the

surface area to mass ratio (Michel, 1987; Burnett et al., 1988). The energy of recoiling atoms is sufficiently high that some atoms cross intraparticle pore spaces and become embedded in adjacent crystal structures. Water in intraparticle pores reduces the energy of the ejected atoms, decreasing the proportion which are re-embedded in other mineral structures. Thus, water may increase the emanation coefficient. High moisture contents may decrease Rn-222 transport to the atmosphere because the gas has a relatively short half-life, and because diffusion of Rn-222 in water is several orders less than in air. Transport of Rn-222 in solution may be substantial if water is rapidly flowing through the mineral matrix in which Rn is emanating. Some Rn-222 progeny are relatively long-lived and may be transported long distances in water (Upchurch et al., 1991).

Thorium. Thorium radionuclides occur in the +4 oxidation state and form sparingly soluble compounds with hydroxides, fluoride and phosphate. Compounds of chloride, nitrate and sulfate are relatively soluble. Complexes with fluoride, chloride, nitrate, phosphate and sulfate dominate its solution chemistry. Total Th in solution decreases as pH is increased to 5. At >pH 5 further pH changes have little effect on Th concentration in solution due to the formation of $Th(OH)_4^0$. Thorium readily hydrolyzes in acidic environments. Adsorption of Th to surfaces increases with pH and decreases in soil particle size. The element has been reported to migrate mainly in polymeric colloidal form (Ames and Rai, 1978). Th-228 and Thorium-230 are more commonly found in groundwaters than is Th-232. Thorium isotopes from the U-235 decay series are not very prevalent due to the scarcity of the U-235 parent (Osmond et al., 1985).

Lead. Most Pb-210 will be partitioned into the phosphoric acid during the wet phosphoric acid process. The activity of Pb-210 in phosphogypsum will therefore be determined by the ingrowth of Rn-222 and its 3.82 day half-life. In the U-238 decay series Pb-210 is the first decay product after Rn-222 which has a half-life of any significant length (21 years). Lead-210 decays via beta-decay and is not as much of a health risk as the alpha producing radionuclides, but its long half-life assures that it will exist for long periods of time. Also significant is the fact that it decays to eventually form Po-210, which is a relatively long-lived alpha emitter (138 days). The rate of ingrowth of subsequent decay products is determined by the half-life of Pb-210. Lead speciation and solubility are controlled by Eh and pH. The element exists in the +2 and +4 oxidation states but the +2 state usually dominates. Solubility is low (2 mg l^{-1}) except in acidic environments (Upchurch et al., 1991). Lead carbonate and $PbSO_4$ are quite insoluble and often control the solubility of lead in oxidizing environments. Under reduced conditions Pb is likely to precipitate as PbS. Adsorption onto clays and organic materials may keep solution concentrations low.

Polonium. Most Po-210 is partitioned into the phosphogypsum during wet phosphoric acid production. Polonium-210 has been found to be abundant in groundwater aquifers below mined lands in Florida where it constitutes most of the gross alpha activity. This radionuclide exists in several valence states with the +4 being the most common. However, the chemistry of Po is not clearly understood (Upchurch et al., 1991). Polonium mobility is controlled by the solubility of the radiocolloids formed by complexing of the element with hydroxyl. Polonium is most mobile in acidic systems. Under alkaline systems it forms a polonium-hydroxyl radiocolloid, often co-precipitated with iron-hydroxyl colloids, which are not very mobile (Upchurch et al., 1991). Complexes between Po and organic compounds may also be important in Po mobilization (Oural et al., 1989). Upchurch et al. (1991) state that there is little direct evidence that ion exchange or redox reactions play a large role in Po mobilization. However, they do note that Po solubility may be influenced by redox reactions of S. Polonium solubility is high in reducing, sulfide rich waters. Particulate Po increases as sulfide is oxidized (Harada et al., 1989). If redox conditions and soluble organic matter levels are suitable for sulfate reduction it is likely that Po-210 will become mobile if pH is not too high.

3.4. Studies of solubility-controlling solids

There have not been very many studies which

have examined the factors which control the mobilization of trace elements and radionuclides in phosphogypsum. Most chemical studies have focused on the elemental composition of the material, or have been empirical leaching studies. Mattigod et al. (1990) and Eary et al. (1990) proposed that these types of studies should be complemented with studies which examine the thermodynamics of specific dissolution/precipitation, adsorption/desorption, and speciation reactions which occur during the weathering of industrial by-products. This latter approach permits predictions of leachate behavior under a wide range of conditions which are not possible with empirical leaching studies. If solubility-controlling solids of an element are present in a waste, or may precipitate from it, then the long-term aqueous concentrations can be predicted from thermodynamic data and adsorption/desorption reactions may be ignored (Eary et al., 1990). Even though thermodynamic data are available for pure-phase secondary solids containing trace elements, there is a lack of data for solid solutions, especially those for radionuclides. If conditions for solubility-controlling solids are not present, or if kinetics are too slow, then dissolution rates and/or adsorption reactions will dominate (Eary et al., 1990). In nature non-equilibria may occur as a result of slow kinetics or microbial catalysis. Changes in the oxidation state of some elements will also influence the above processes. Acidic, aerobic conditions would be expected to define the pore water chemistry of phosphogypsum, however reduced conditions may develop near the base of a stack. The pH of phosphogypsum may approach neutrality as the material ages.

The application of chemical speciation to predict the mobility of trace elements in phosphogypsum and phosphogypsum process water is lacking. Of the little speciation data which has been published, most has been for the major rather than for the minor elements. Murray and Lewis (1985) used GEOCHEM to predict the fate of fluoride, orthophosphate and sulfate from phosphogypsum leachate as it reacted with simulated soil systems. Their results will be elaborated in a later section. Lewis (1988) extended this work further by examining the fate of Ra-226 species originating from uranium mill waste solutions in simulated soil systems using GEOCHEM. The simulated and experimental results did not match very closely. The inconsistency was explained by Lewis (1988) as being the result of a poor data base for Ra-226 species, particularly for mixed-solid species. Radium is known to form solid solutions with some elements such as Ba and Sr (Langmuir and Melchoir, 1985); however, thermodynamic data for Ra solid solutions are not complete.

May and Sweeney (1984b) evaporated the leachate water from phosphogypsum but X-ray diffraction of the evaporite did not help to identify any trace element compounds. Literature studies of phase equilibria in saturated gypsum solutions were used to identify possible trace element compounds. The expected specific compounds of trace elements were sulfates, except for the Ca compounds of arsenate, chromate and selenate.

Luther and Dudas (1993) examined solution extracts from 80-day batch incubation studies of phosphogypsum, phosphogypsum-soil mixtures and soil alone. Speciation of major and trace elements was performed using GEOCHEM. As pH was raised due to soil addition most free cations decreased, OH^- interactions increased and PO_4^{3-} and SO_4^{2-} interactions decreased. Concentrations of Cd, Fe, Ni, P, Sr, V, and Zn in solution decreased by close to an order of magnitude. Soil addition increased Ca^{2+} and Cd^{2+} interactions with SO_4^{2-}. AsO_4^{3-}, CO_3^{2-}, PO_4^{3-} and SeO_3^{2-} were mainly combined with H^+ in phosphogypsum leachate and the proportion decreased with neutralization. Nitrate, SO_4^{2-} and SeO_4^{2-} existed mainly in the free state and this fraction increased with neutralization.

Luther and Dudas (1993) also compared ion activities predicted by GEOCHEM with theoretical levels using solubility constants for potential solubility-controlling solids of Al, As, Ca, Cd, Cu, Fe, P, S, Se, Si and Zn. Aluminum activities were consistent with the presence of the solubility-controlling solids of alunite, basaluminite, gibbsite and jurbanite. Under acidic conditions and high sulfate levels the aluminosulfate minerals alunite and basalunite were predicted to be the most stable (O'Brien and Sumner, 1988; Alva et al., 1991).

Solubility-controlling solids for the trace ele-

ments could not be identified by Luther and Dudas (1993) because solutions were undersaturated relative to the potential minerals for which thermodynamic data were available. Thus the effects of precipitation/dissolution and adsorption/desorption could not be resolved. Spiking the material with trace elements might allow for the prediction of solubility-controlling solids if they existed (Rai and Szelmeczka, 1990). The batch incubations showed that Cd concentrations were high in phosphogypsum pore water but concentrations of this element, along with Cu and Zn, decreased greatly with increases in pH. Arsenic and Se concentrations did not decrease greatly with pH increases and, along with SO_4^{2-} and F^-, were identified as potentially posing an environmental risk if leached downwards into groundwater systems.

4. Environmental concerns related to the storage of phosphogypsum

Most of the phosphogypsum produced is stored in stacks (Carmichael, 1988). A recent final ruling by the U.S. E.P.A. requires that all phosphogypsum be placed in stacks or mines (Federal Register, 1990). Environmental contamination resulting from phosphogypsum storage may occur from: (i) atmospheric contamination with fluoride or other toxic elements; (ii) groundwater pollution with mobile anions, acidity, trace elements or radionuclides; (iii) radon gas; (iv) inhalation of radioactive dust; and (v) direct exposure of gamma radiation. Other concerns with storage include surface runoff (Rydzynski, 1990), and erosion and stability of the stacks. Several authors have published methods of reducing fluoride, radionuclides and heavy metals in phosphogypsum by treatments before, during or after the wet phosphoric acid process (Becker, 1989; Jdid et al., 1986; Kazak et al., 1988; van der Sluis et al., 1988; Habashi, 1989; Moisset, 1990). Mitigation and closure of phosphogypsum storage sites are discussed by Berish (1990) and Norlander (1988).

4.1. Atmospheric fluoride

Fluoride gas emission is only a concern with operational stacks; however, transport of fine dust particles containing F^- is a potential problem for both operational and inactive stacks. Phosphate rock may contain 4% fluorine which forms HF during the acidulation process. Fluoride remains in the liquid phase but during processing gaseous SiF_4 and gaseous HF may be formed under high temperature conditions. When phosphogypsum is sluiced to the stack some gaseous F^- may be evolved; however, most plants use scrubbers to remove F^-.

Linero and Baker (1978) evaluated previous F^- emission rate studies to determine a F^- emission factor which could be used for predictive modelling. None of these studies were ideal, however it was concluded that the characteristic emission factor for cooling ponds fell in the range of 0.1–10 lb acre^{-1} day^{-1} (30–3400 μg cm^{-1} 30 days^{-1}). Modelling predicted that ambient F^- concentrations near a typical pond would be sufficiently high to require technologies to control F^- emission.

SENES (1987) discussed the F^- monitoring programs in place at two sites in Canada. The Ontario site was the focus of two phytoxicological surveys. The results of this monitoring showed that probably only operating facilities result in elevated ambient F^- levels. The Ontario Ministry of the Environment (OME) established 35 μg g^{-1} as the upper limit of normal background concentration of F^- in foliage. During plant operation foliage samples exceeded this level as far away as 6 km from the plant site (McLaughlin, 1986). Wild grape, a plant very sensitive to F^-, showed damage in the areas surrounding the plant site.

Fluoridation rates in the area surrounding the Ontario site were measured by the OME. Annual averages ranged from 18 μg F^- 100 cm^{-2} 30 days^{-1} at a station 5.4 km away to as high as 927 μg F^- 100 cm^{-2} 30 days^{-1} at a station close to the operating site. Seasonal variation of ambient fluoridation levels was observed to be greatest in the summer. Fluoridation rates declined greatly when operation of the phosphoric acid plant ceased (SENES, 1987).

Ambient fluoridation levels were also measured immediately adjacent to the ponds and plant at an operating site in Calgary, Alberta. Seasonal and spatial variation was observed with rates ranging

from a low of 6 μg F 100 cm^{-2} 30 $days^{-1}$ to a high of 5170 μg F 100 cm^{-2} 30 $days^{-1}$. Maximum air quality guidelines for fluoridation levels are 40 μg 100 cm^{-2} 30 $days^{-1}$ in Alberta, and 80 and 40 μg F 100 cm^{-2} 30 $days^{-1}$ in Ontario for growing and non-growing seasons, respectively.

4.2. Groundwater pollution

Groundwater contamination may occur from process water seepage during operation of a stack or through the long-term downward leaching which occurs when rainwater infiltrates through an inactive stack.

Several studies have investigated groundwater pollution or the potential leachability of phosphogypsum constituents. The results are not consistent although it is clear that the potential for groundwater pollution under a phosphogypsum stack is a concern in some situations.

Acidic seepage waters may be buffered by alkaline subsoils and groundwaters, thereby reducing the mobility of certain heavy metals (e.g. Ni, Co,

Cu) (SENES, 1987). However, other chemical species such as SO_4^{2-} and F^- are not affected as much by pH changes from the stack to the subsoil. Site specific conditions which may mitigate the impact of possible contaminants on groundwater are: (i) suitable subsurface geology which can neutralize acidic seepage; (ii) construction of the stack on an impervious layer; and (iii) construction of interceptor wells or ditches. Other sources have reported methods of reducing seepage of contaminants from active and inactive stacks (Gipson, 1985; Wissa, and Fuleihan, 1980; Wrench and Smith, 1986; Kleinschmidt, 1990; Rouis and Bensalah, 1990).

dic. Sulfuric, phosphoric and fluoridic acids reside in the phosphogypsum pores after acidulation and filtration. Consequently, elements solubilized from phosphate rock during the acidulation process may remain in solution. This process water is present in cooling ponds and also within the porosity of the phosphogypsum stack.

The species solubilized during acidulation include As, Cd, Cr, Pb, Na, F^-, Mn, Fe, SO_4^{2-}, U and Th (Roessler, 1979a; Berish, 1990). In addition to toxic elements, the process water contains high levels of total dissolved solids (Rea and Woods, 1985). Elemental composition of process waters is reported in Tables 7 and 8. The waters do not meet many of the limits set for drinking water regulations and guidelines (Table 6).

Laboratory studies. Murray and Lewis (1985) determined the extent to which natural geological materials could remove fluoride, sulfate and orthophosphate from phosphogypsum leachate under laboratory conditions using graded, serial batch leaching systems. The minerals investigated were sand, Ca-montmorillonite, kaolinite, calcium carbonate and iron (III) hydroxide. The chemical equilibrium model GEOCHEM was used to speciate the leachate solutions. Calcium carbonate removed large proportions of F^- and orthophosphate and smaller proportions of sulfate by precipitation as CaF_2, calcium phosphate and/or calcium fluorophosphate and $CaSO_4$. Sufficient calcium carbonate was needed to maintain a high solution pH, otherwise redissolution of F and orthophosphate occurred. Sand only removed small quantities of F^-, probably by anion adsorption. Both kaolinite and montmorillonite removed large quantities of soluble F and orthophosphate from solution. The removal increased with increasing pH, likely due to a combination of complex formation, the degree of phosphate ionization and changes in clay charge characteristics. The removal of F^- by kaolinite was probably due to positive charge development on the clay. At pH 4, 84% of F existed as free F^- and the AlF_4^- complex. Iron(III) hydroxide had little effect on F^- or orthophosphate removal when mixed with clays but markedly increased SO_4^{2-} removal when Ca was abundant, probably by the formation of Ca phosphate complexes which reduce competition with sulfate for adsorption on clays or Fe (III) hydroxide. According to Murray and Lewis (1985) calcareous strata below phosphogypsum may be very effective in precipitating F^- and orthophosphate.

May and Sweeney (1984b) evaluated the leachability of Ra and elements the E.P.A. has classified as toxic by using the standard E.P.A. 'EP' extraction procedure (Federal Register, 1980). Additional elements (Cu, Ni, K and Na) were included in the analysis. The concentrations of toxic elements in the extract were all below E.P.A. maximal concentrations, therefore the material was considered non-toxic by E.P.A. standards. The authors estimated that the inclusion of Ra into the phosphogypsum crystal structure would be 89% of the amount originally present, indicating that very little Ra would be leached. May and Sweeney (1984b) estimated the Ra to move at approximately 1/200 the seepage rate.

SENES (1987) conducted leachate studies on two composite phosphogypsum samples taken from sites located at Dunnville, Ontario and Calgary, Alberta. The Ontario material was from an inactive stack while the Alberta material was taken from an active stack. The leachate test involved agitating the solid in distilled water (1:10 ratio) for 24 h followed by filtering. All measured concentrations of toxic elements were below the E.P.A. criteria, although the Cd and Cr concentrations from the Alberta site were much greater than values found at the Ontario site or by May and Sweeney (1984a) in Florida phosphogypsum. The Alberta phosphogypsum was acidic due to the presence of residual process water. Relatively high concentrations of Al, Cd, Cr, Fe, Mg, Ni and V were attributed to the low pH and relatively high solubility of the metallic hydroxides (SENES, 1987). The leachate from the Ontario phosphogypsum had a pH of 6.02. Although it contained elevated levels of Ca, SO_4^{2-}, P, F^-, and Al, they were lower than those from the Alberta material. Heavy metal concentrations were much lower than in the Alberta phosphogypsum leachate. According to SENES (1987), the results showed that leachate from fresh phosphogypsum exceeded both mining discharge objectives and Canadian drinking water standards. Aged phosphogypsum

may meet mining discharge objectives except for P, Al and possibly Cd. Fluoride and SO_4^{2-} levels are likely to be exceeded even in aged phosphogypsum material (SENES, 1987). Lead-210, a relatively long-lived radioactive product from the U-238 decay chain, was 100-fold greater in the Alberta phosphogypsum leachate than in the Ontario phosphogypsum leachate and exceeded the World Health Organization Guideline for beta particle activity (1.0 Bq l^{-1}) by three times.

Naff (1984) conducted a leachate study to determine the potential environmental impact of phosphogypsum from Mobil Chemical Corporation. Fresh, aged and stabilized phosphogypsums were analyzed using the standard E.P.A. EP extraction procedure. The results were within the permissible E.P.A. limits for toxicity, however SO_4^{2-} and fluoride levels exceeded drinking water standards.

Luther et al. (1993) determined the equilibrium concentrations of major and trace elements in phosphogypsum pore water taken from an inactive phosphate plant in southern Alberta in order to evaluate the groundwater contamination potential of phosphogypsum. Some extracts had higher levels of As and Cr than those found by May and Sweeney (1984b), but all pore water samples were more concentrated in Cd and Se. Luther et al. (1993) determined that all extract samples exceeded Canadian drinking water guidelines (CDWG) for Cd, Se, SO_4^{2-} and total dissolved solids. Some samples exceeded CDWG for As, Cd, Cr, Cu, Fe, Mn, Na, NO_3-N and Zn (Table 6). The pH of the pore water extract was 3.4, which is below CDWG. Fluoride levels were not measured by Luther et al. (1993); however, Roberts-Thorne (1990) determined levels to be 26 $\mu g\ g^{-1}$ at the same site a few years earlier. Canadian DWG requires fluoride to be $<1.5\ \mu g\ g^{-1}$ (Health and Welfare Canada, 1993).

Field studies. SENES (1987) summarized work by Miller and Sutcliffe (1982) for two operational stacks in central Florida (AMAX Phosphate Inc. and USS Agric-Chemicals Ltd.) which are located on limestone bedrock that is overlain by phosphatic clay deposits and a surficial sand layer. Groundwater in the area is characterized by hard, calcium magnesium bicarbonate water with low SO_4^{2-} and Cl^- concentrations. Both stacks caused slight distortions in the groundwater level which reflected recharge of water from the stack and pond areas. Significant degradation in groundwater quality was detected at the two sites. Many chemical parameters showed levels up to several orders of magnitude greater than natural groundwater concentrations. Relative to background concentrations, the groundwater below the two sites showed elevated concentrations of Si, Na, SO_4^{2-}, F^-, hardness, P and N. Concentrations of Cu, Mo and Zn were also elevated. Low pH was also found near the gypsum stacks and cooling ponds at the USS site. Movement of contaminants in a plume was observed at both Florida sites. Groundwater 600 m from the USS stack showed sulfate concentrations which were 450 times greater than background levels. Groundwater 460 m from the AMAX stack had sulfate concentrations up to 1900 mg l^{-1} (SENES, 1987). Selected members from the U-238, U-235 and Th-232 decay chains were also measured in the groundwater below the AMAX site. Radium-226 was measured below the USS site. All radionuclides, except for Ra-226 at the USS site, were within drinking water standards, however U-238 was elevated over background in some samples. At both sites elevated levels of Ra-226 were observed hundreds of meters from the stacks, indicating Ra-226 migration through the groundwater systems (SENES, 1987).

SENES (1987) reviewed groundwater studies which have been conducted near phosphogypsum stacks in Alberta at sites operated by three fertilizer manufacturers. All sites are located on relatively flat terrain underlain by glacial till. Near surface groundwater quality is poor so drinking water and irrigation water is obtained from deep groundwater or surface water. It was not possible to compare groundwater quality between sites because different monitoring criteria were used at each site. The criteria set for background levels were conservative and were based on taking the lowest values observed in observation wells to represent background levels. Sulfate concentrations were found to be much greater than apparent background. Fluoride concentrations of up to 32 mg l^{-1} were detected, which are several orders of magnitude greater than background. SENES

(1987) did not think that heavy metals would be very mobile in these groundwater systems because pH values ranged between 6.5 and 8.7. Levels of Ca, P and N species were elevated above background in some wells.

May and Sweeney (1984b) supplemented their laboratory studies (see above) of the leaching characteristics of phosphogypsum stockpiles by detailed sampling through a short section both above and below the ground:phosphogypsum interface. Subsurface analysis was not available prior to phosphogypsum stacking and was estimated using averages from similar geological materials. It was concluded that Ra-226 and metallic elements were not leached from the phosphogypsum stockpiles.

Toxicity analysis of phosphogypsum was conducted by May and Sweeney (1982, 1984a, 1984b) on nine Florida stacks in order to assess the potential environmental impact of the material. Both active and inactive stacks were included in the study. Part of the study involved measuring the total elemental composition throughout the stack profile. The researchers hypothesized that if significant leaching of elements occurred, there would be a non-uniform distribution of elements down though the stack. They concluded that significant leaching had not occurred because a uniform distribution of elements was found.

Berish (1990) summarized a groundwater study conducted in Florida by Bromwell and Carrier (1987). Data from surficial groundwater at four phosphogypsum sites in Florida were used to calculate distances downstream from a theoretical phosphogypsum site at which contaminant concentrations would not exceed E.P.A. Drinking Water Standards. Concentrations of Se, Ag and F^- were attenuated quickly and were below the E.P.A. maximum contaminant levels for Primary Drinking Water Standards within 100 feet of the source. Lead and As concentrations met these standards within 300 feet and 800 feet, respectively. Cadmium and Cr were more mobile and were not attenuated until up to 1200 feet from the source. Iron, SO_4^{2-}, Mn and total dissolved solids were very mobile but limited data made it difficult to make an accurate estimation of the size of the impact zone. However, it was estimated that the non-exceedance zone would be greater than 610 m from the source and would be highly dependent on site specific geologic and hydrologic conditions. Shallow surficial aquifers were the main groundwater systems contaminated by phosphogypsum stacks.

Rouis and Bensalah (1990) investigated the groundwater contamination below a phosphogypsum stack in Tunisia. The pH of the groundwater near the stack was less than 2. It was neutral 200 meters downstream from the stack. Phosphate and F^- levels near the stack were as high as 16300 and 8800 mg l^{-1}, respectively. Mercury and Mo levels were as high as 0.60 and 0.19 mg l^{-1}, respectively. The region of high groundwater contamination extended 100 to 400 meters downstream from the phosphogypsum stack.

Other studies have investigated the groundwater pollution potential of phosphogypsum which has been used as a base for road construction (Chang et al., 1989; Bandyopadhyay et al., 1990; Nifong, 1990). These studies reported no adverse effects of phosphogypsum on groundwater quality.

4.3. Radon gas and other radioactive exposure

Roessler (1986) summarized the pathways of radioactive exposure originating from phosphogypsum to humans. Exposure to Rn-222 gas is one of the greatest health concerns. This section will review the studies which have investigated the magnitude of Rn-222 gas evolution and the significance of these rates. Other forms of aerial exposure, such as radioactive dust particles and direct gamma radiation from phosphogypsum stacks, will also be included in this section. Before discussing Rn-222 it is appropriate to summarize simple dosimetry, the means by which radioactive exposure is measured. A more comprehensive description of the subject is offered by references such as Cothern (1987) or Lao (1990).

Several terms are used to describe the health effects of radionuclides such as Rn-222 and its progeny. The working level (WL) has been in use since 1955 and describes the potential alpha energy concentration of radon progeny. A WL is defined as the exposure rate of 1.3×10^5 MeV (2.08×10^{-5} J) of potential alpha energy/liter of air. This is the energy released from the total decay of short-

lived Rn-222 progeny to Po-214 in radioactive equilibrium with 3700 Bq m^{-3} (100 pCi l^{-1}) of Rn-222. The working level month (WLM) corresponds to an exposure of 1 WL during 1 month (approx. 170 h). In terms of radon progeny concentration, a WL of 0.001 is representative of average outdoor concentrations. Average indoor levels are 0.004 WL. The level recommended for remedial action by the U.S. National Council on Radiation Protection and Measurements (NCRP, 1984) is 0.04 WL. Assuming 0.5% equilibrium between radon and its progeny, this is equivalent to a radon concentration of 300 Bq m^{-3} (8 pCi l^{-1}). This results in a continuous exposure rate of about 2 WLM/year (Mills and Egan Jr., 1987). In Canada, remedial measures are recommended when average indoor Rn-222 daughter concentrations exceed 0.02 WL (NCRP, 1984).

Walsh (1990) provided a theoretical argument that current mining risk coefficients, such as the WL, significantly overestimate environmental radon risk because miners are exposed to a complex atmosphere that contains many substances which may potentially cause cancer. Current lung cancer risk assessments assume that radon progeny alone are responsible for differences between miners and control populations.

The absorbed dose, D, refers to the average density of energy absorbed by a mass of cells. In the SI system the unit is the Gray (Gy), equivalent to J kg^{-1}. The conventional unit for absorbed dose is the radiation absorbed dose (rad), which is equivalent to one hundredth of a Gray.

The dose equivalent, H, is a measure of both the energy absorbed by a mass and the biological impact of the absorbed energy. Measured in Sieverts (Sv), it is the product of the absorbed dose, D, the quality factor, Q, and a factor, N (usually 1), which incorporates other modifying factors. The conventional unit for H is the radiation equivalent in man (rem), which is equivalent to one hundredth of a Sievert. The quality factor, Q, is small for gamma and X-rays (1), intermediate for neutrons (5), and high for alpha particles and other heavy nuclei (20). Thus for gamma radiation the radiation absorbed dose (rad) is usually the same as the radiation equivalent in man (rem). The dose equivalent of an organ is calculated by multiplying H by a weighting factor which takes the radiosensitivity of an organ into consideration. The NCRP (1984) recommendation for general public continuous exposure to gamma radiation above background is 1000 mrem (10 mSv) $year^{-1}$. Typical exposure to background gamma radiation in the U.S. is 0.28 mSv $year^{-1}$ (28 mrem $year^{-1}$). Canadian estimates are 20% lower (NCRP, 1987).

The effective dose equivalent, (H_E), is a measure of the total risk to the individual and is calculated by summing the dose equivalents of all the organs in the body. Both H and H_E are measured in Sv. The annual effective dose equivalent for all sources of natural background radiation is approximately 2 mSv $year^{-1}$, which is approximately equal to 200 mrem $year^{-1}$ (UNSCEAR, 1982; Cothern, 1987).

Field studies. A number of studies have investigated radon exhalation rates, ambient radon levels and other forms of radioactive exposure at phosphogypsum stacks. To put these values in perspective, typical exhalation rates from soil, the largest source of background radon in the environment is approximately 0.5 Bq m^{-2} s^{-1} per Bq Ra-226 g^{-1} soil (NCRP, 1987). The average concentration of Rn-222 in the global atmosphere is about 3.7 Bq m^{-3}, however concentrations may be 10-times higher over some land areas. Typical Rn-222 levels near open ground are about 5 Bq m^{-3} (Eichholz, 1987; Michel, 1987).

Windham and Horton (1980) reported the exhalation rates of Rn-222 from two active phosphogypsum stacks in Polk County, Florida over several weeks. The mean exhalation rate was 1 Bq m^{-2} s^{-1} although measured rates varied by almost two orders of magnitude. Guidry (1990) reported radon flux from a phosphogypsum stack in central Florida to range from <0.004 Bq m^{-2} s^{-1} over ditches and beaches on the stack to 3.6 Bq m^{-2} s^{-1} near a roadway on top of the stack. A wide range of variation was observed on the stack, likely due to differences in crusting.

NESHAPS (1989) summarized by Berish (1990) reported Rn-222 exhalation rates from active and inactive stacks in Florida. The greatest flux rates were from the top of dry non-crusted stacks which were active. This material averaged about 0.7 Bq m^{-2} s^{-1}. In contrast, exhalation rates were less

than 0.04 Bq m^{-2} s^{-1} from cooling ponds and ditches. Flux from the top of an inactive stack only averaged 0.15 Bq m^{-2} s^{-1} but flux from the sides of a different inactive stack was about four times greater. NESHAPS (1989) also estimated total Rn-222 fluxes from many stacks throughout Florida. Flux rates were estimated to range between 0.09 and 0.34 Bq m^{-2} s^{-1}. The computer codes AIRDOS-EPA and DARTAB were used to estimate the maximum exposed individual and also the collective risks of the regional population to Rn-222. Meteorological conditions and distance from the stacks were considered. The maximum exposed individuals were estimated to receive doses $<6 \times 10^{-5}$ WL above the natural background outdoor level. Collective risk assessment estimated that less than one fatal cancer in 20 years would occur due to the presence of phosphogypsum stacks. Based on this work, the U.S. E.P.A. recently adopted an average 0.74 Bq m^{-2} s^{-1} limit on Rn-222 emissions from phosphogypsum stacks (Federal Register, 1989).

Horton et al. (1988) reported Rn-222 concentrations around the perimeter of 5 phosphogypsum stacks 1 m above ground level. Natural background levels, determined at nine locations greater than 8 km from any phosphogypsum stack, averaged 0.0052 Bq l^{-1}. Average concentration at the base of the phosphogypsum stacks was 0.024 Bq l^{-1}. Roessler (1985) reported Rn-222 concentration to range between 0.011 and 0.015 Bq l^{-1} on or close to a phosphogypsum stack. Concentrations decreased to background within 1000 m.

SENES (1987) found Rn-222 exhalation rates from some stacks at Ontario (clay or topsoil covered stacks) and Alberta (active with bare phosphogypsum dikes with water-filled ponds) to range between 0.037 and 1.1 Bq m^{-2} s^{-1}. A typical value of 0.37 Bq m^{-2} s^{-1} was incorporated into the air dispersion model ISC-LT (Wackter, 1986) which estimated Rn-222 air concentrations under meteorological conditions representative of the two sites. At Ontario, it was predicted that maximum annual average Rn-222 concentrations 100 m from non-water covered, bare phosphogypsum stacks would be 1.1–1.9 Bq m^{-3} (0.0011–0.0019 Bq l^{-1}). Concentrations 100 m from water covered stacks would be approximately 0.19 Bq m^{-3} (0.00019 Bq l^{-1}). Some measured background levels in the vicinity were higher than this. The results for the Alberta site were similar in that predicted Rn-222 concentrations 100 m from the stacks were indistinguishable from normal background levels. SENES (1987) also measured ambient Rn-222 concentrations 1–1.5 m above stacks covered with clay in Ontario. The average concentration of 0.011 Bq l^{-1} was not statistically different than background levels (0.0074 Bq l^{-1}) for the area. Radon-222 concentration above water ponds at a phosphogypsum stack in southern Alberta averaged 0.024 Bq l^{-1}, which was not statistically different from the natural background level of 0.017 Bq l^{-1}.

Airborne particulate matter originating from phosphogypsum piles by wind erosion or operations on the stack is also a potential source of radioactivity. Wind erosion is usually not a serious problem on stacks because inactive stacks develop a crust while active stacks generally have a high moisture content which reduces blowing particles (Berish, 1990). NESHAPS (1989) found that annual radionuclide transport from a phosphogypsum stack was very low and the associated health risks were much less than those related to Rn-222 emissions. Similar findings were found by Western and SENES (1983). Air samples were taken 0.8 km south of one phosphogypsum pond in southern Alberta and analyzed for U, Th-230, Ra-226, Pb-210 and Po-210. All radionuclides except Ra-226 were within background levels. The annual Ra-226 intake was estimated to be equivalent to 2.5 μSv which is much less than 2 mSv, the typical annual exposure to natural background radioactivity.

Phosphogypsum stacks are a direct source of gamma radiation due Ra-226 and its daughter radionuclides. Horton et al. (1988) reported gamma radiation 1 m above the surface of 5 phosphogypsum stacks. Average gamma exposure was 33 μrads h^{-1} (33 μrem h^{-1}). Berish (1990) stated that only people spending long periods of time working on the stack, or living immediately adjacent to it, would be subjected to a health risk because irradiation decreases exponentially with distance. Roessler (1986) (see below) did not think this level of gamma exposure posed an environmental health risk.

Laiche and Scott (1991) conducted a study to determine the potential radiological exposure for people working at the Freeport phosphogypsum pile in Louisiana. Gross gamma exposure rates were measured 1 m above the stack surface. Air samples were also obtained from the same location. The measured gross gamma exposure rates averaged 0.368 μSv h^{-1}. The corresponding working year exposure would be 0.48–0.68 mSv above background. This level is low because it represents <10% of the annual dose limit for the general public in unrestricted areas (NCRP, 1984). Radon daughter concentrations measured on the stack ranged between 0.0006 and 0.001 WL, while airborne Ra-226 concentrations were indistinguishable from background.

Roessler (1986) conducted a detailed analysis of the radiological hazards associated with phosphogypsum produced from central Florida rock. He used radiological characteristics of phosphogypsum from a number of sources to determine the exposure hazard of the gamma radiation and air borne radioactivity in the immediate vicinity of the phosphogypsum piles. It was determined that individuals working on a phosphogypsum stack for a year (2000 h) would be subjected to a gamma radiation dose equivalent of 60 mrem. The occupational exposure limit is 5000 mrem $year^{-1}$. Measured radon concentrations were equal to or less than 0.015 Bq l^{-1} which corresponds to <0.004 WL. This level was equivalent to typical Florida indoor radon concentrations and 10-times less than the level set by the NCRP for remedial action.

Guidry (1990) conducted a detailed analysis of the radon emissions and gamma radiation irradiated from a phosphogypsum stack in central Florida. Radon emission data and measurements of airborne Ra-226 in particulate matter were utilized in the ISCLT atmospheric model to estimate the environmental impact of the stack. The receptor sites for the radiological assessment were located at the nearest point of general public access to the facility, approximately 2000 m from the stack, and also at the location of the maximum exposed individual (MEI). Estimated maximum radon daughter levels at the nearest public access point corresponded to 0.000065 WL while the maximum concentration at the location of the MEI was less than half of this amount. It was estimated that deposition of Ra-226 in particulate matter for 1000 years would increase soil Ra-226 <0.1%.

5. Utilization of phosphogypsum in agriculture

Many studies have reported the effects of applications of phosphogypsum on nutrient levels and the physical and chemical properties of agricultural soils. The benefits of phosphogypsum have been documented as amendments for: (i) highly weathered soils, with relatively low exchange capacities and/or low levels of extractable nutrients; (ii) soils with high sodicity resulting in dense subsoil horizons, and those with variable sodicity at the surface which are prone to dispersion and crusting; (iii) acid soils with high levels of Al; and (iv) calcareous soils. Crop yields and quality of a variety of fruit, vegetable, grain, forage, and oilseeds have generally been found to be higher on phosphogypsum amended soils. The wide scale use of phosphogypsum appears to be restricted until concerns regarding associated natural radionuclides, F^-, heavy metals, effect on nutrients, potential as a source of P in surface water pollution, and economic considerations are more fully addressed. Despite these environmental concerns regarding phosphogypsum, some countries have made wide-scale use of the by-product as a soil amendment (Beretka, 1990; Novikov et al., 1990). Phosphogypsum has also been used in agriculture as a feed additive for livestock (Golushko, 1984) and as a fertilizer amendment to reduce ammonia volatilization from urea fertilizer (Boyrakli, 1990), however, use as a soil amendment has been reported most extensively.

5.1. Source of plant nutrients

In plant nutrition studies, phosphogypsum has been used as a source of Ca, S, and P on a broad range of soils differing in pH and fertility. The effectiveness of phosphogypsum as a nutrient source has been attributed to its relatively rapid dissolution rate and its capacity to supply relatively large amounts of soluble nutrients during critical phases of crop growth (Malavolta et al., 1987; Bianco et

al., 1990; Gascho and Alva, 1990; Singh et al., 1990). While P_2O_5 comprises a rather small percentage of phosphogypsum material (<1%), high application rates may significantly increase available soil P (Broadbent et al., 1989; Khalil et al., 1990).

Some studies have described the influence of phosphogypsum on the availability and uptake of other nutrients. Phosphogypsum increased the availability of Fe and Mn through a localized acidifying action around roots, and increased the availability of N, P, K, and Mg in calcareous soils (Khalil et al., 1990; Singh et al., 1990). Magnesium and/or K displaced from the exchange complex by Ca derived from phosphogypsum may be subsequently leached from the zone of interest (Pavan et al., 1987; Sumner et al., 1988; Gasho and Alva, 1990). However, excess Mg and K have been linked to peanut pod rot and leaching of these cations from the pegging zone (0–8 cm) had a beneficial effect on production (Gasho and Alva, 1990).

The beneficial effect of phosphogypsum for controlling diseases is noted in some studies. Phosphogypsum either directly influenced the reduction of phytophthora infection of citrus roots or affected plant nutrition in a way which depressed fungus development on the roots (Smith et al., 1989; Nemec et al., 1990).

5.2. Reclamation of acid soils

The need to develop practical methods to ameliorate subsoil acidity is important because many acid soils in tropical and subtropical areas are used for food production. Phytotoxic Al levels, sometimes accompanied by deficient Ca levels and/or clay hardpans, may restrict root exploitation of subsoil horizons (Shainberg et al., 1989). Crops, grown on such soils, are unable to use moisture and nutrients below ameliorated surface horizons.

When phosphogypsum is applied to acid soils, field and lab studies have found: (i) decreased levels of exchangeable and solution Al; (ii) increased levels of exchangeable and solution Ca; (iii) small and/or somewhat variable effects on pH; and (iv) enhanced root growth (Pavan et al., 1987; O'Brien et al., 1988; Alva et al., 1988, 1990, 1991; Alva and Sumner, 1990; Mathews and Joost, 1990). The formation of less phytotoxic ion pairs and complex ions, mineral precipitation and, in some highly, weathered soils ionic strength induced adsorption were proposed as possible mechanisms for the reduction of exchangeable and solution Al (Pavan et al., 1987; Sumner et al., 1988).

Calcium exchange for H^+ and Al species, and SO_4^{2-} replacement of OH^- by ligand exchange, affect pH. In highly weathered soils, these opposing processes are often nearly balanced owing to relatively large quantities of hydroxylated surfaces on sesquioxides available for ligand exchange, as well as a low cation exchange capacity and therefore low exchangeable acidity (Shainberg et al., 1989).

Phytotoxic Al levels inhibit root growth by disrupting root cell division during mitosis. Root proliferation, as determined by root sampling and water extraction patterns, corresponded with soil zones where Al levels were reduced (Pavan et al., 1987; Sumner et al., 1988). Crop increases in phosphogypsum amended soils were apparently related to reduced phytotoxic Al levels and associated root proliferation rather than phosphogypsum induced changes in pH.

The dissolution rate of phosphogypsum partially controls its effectiveness as an amendment on acid soils and other problem soils. Factors which influence the dissolution rate include particle size, formation of a P and Al enriched skin on phosphogypsum granules, and the method of application. Coarse particles and skins can reduce the dissolution rate and the ameliorative effect of phosphogypsum (Frenkel et al., 1989b). Surface application of phosphogypsum was found to have a less beneficial effect on alfalfa yields and Al-Ca exchange reactions than deep incorporated lime (Sumner et al., 1986).

5.3. Reclamation of sodic soils

Sodic soils often exhibit poor soil structure due to the dispersion of clay particles that occur when high levels of sodium are present on the exchange complex of soils. The large, highly hydrated Na cation is less effective than smaller, divalent Ca ca-

tions at satisfying negative charges on clay surfaces; therefore, the replacement of Na with Ca reduces dispersion and promotes flocculation of soil particles. Phosphogypsum is an effective ameliorant for sodic soils because it supplies sufficient Ca to displace Na from the exchange complex of soils. Also, it has a relatively rapid dissolution rate and a relatively high solubility (Merrill et al., 1980; Okorkov, 1988; McKenzie and So, 1989a; Orlov et al., 1989).

Rates of phosphogypsum applied to sodic soils have been based on replacing a portion of the initial content of Na with an equivalent quantity of Ca. A coefficient of gypsum utilization for the displacement of Na has also been included in rate calculations (Okorkov, 1988). The gypsum utilization coefficient considers the factors which affect the efficiency and rate of Ca displacement of exchangeable Na. The percentage of Ca that exchanges for adsorbed Na will be much greater at high exchangeable Na levels (Shainberg et al., 1989).

Phosphogypsum applied at rates between 2.5 and 30 t ha^{-1} induced replacement of exchangeable Na with Ca (Merrill et al., 1980; Petrov and Savchenko, 1986; Okorkov, 1988; McKenzie and So, 1989a) and resulted in significant reductions in the pH of alkaline, saline, and saline-sodic soils (Mishra, 1980; Orlov et al., 1989). The flocculating effect of Ca on soil particles was found to decrease bulk density, increase porosity, and promote formation of soil structure and aggregate stability (Orlov et al., 1989). These changes in soil physical properties generally enhanced water infiltration and leaching of Na. The amount of infiltrating water, texture and initial hydraulic conductivity of soils were factors reported to affect the extent of leaching.

5.4. Erosion control

Erosion control studies have investigated the interrelated effects of phosphogypsum, precipitation and slope characteristics on soils which exhibit a tendency to disperse and form crusts. These soils are characterized by having high sodicity at the surface, or by containing highly weathered, non-sodic kaolinitic and illitic clays which disperse when water with a low electrolyte concentration is applied (Agassi et al., 1985, 1986, 1990; Miller, 1987; Stern et al., 1991). In general, crusting reduces infiltration and increases runoff and soil loss.

The dispersion process is due, in part, to a chemical mechanism which depends on the exchangeable sodium percentage and the electrolyte concentration of the applied water. The dispersed clay particles may be deposited in the upper few millimeters of the soil (Gal et al., 1984; Frenkel et al., 1989a) or are carried off as sediment in runoff. A second complementary mechanism involves the physical disintegration of surface aggregates under raindrop impact (Stern et al., 1991). When water of high electrolyte concentration is used, chemically induced dispersion is largely prevented and a thin seal with high permeability is formed, mainly by the physical mechanism (Agassi et al., 1985; Frenkel et al., 1989a).

Phosphogypsum application to soil mainly affects the dispersion process by rapidly introducing electrolytes including Ca, into the applied water at the soil surface. This promotes flocculation, enhances aggregate stability and deposition of entrained particles in runoff (Warrington et al., 1989; Agassi et al., 1985, 1990; Agassi and Ben-Hur, 1991). However, phosphogypsum may also inhibit physical disintegration by acting as a mulch to intercept and reduce the impact of raindrops. In general, application of phosphogypsum increases infiltration, decreases runoff, and decreases soil loss compared to control treatments.

The relative effectiveness of phosphogypsum for reducing erosion is partially dependent on the impact energy of rainfall at the soil surface (Smith et al., 1990). Other factors include slope gradient and length, application rate and method, and other agronomic practices. Agassi et al. (1990) found that the beneficial effect of phosphogypsum was less pronounced when the impact of raindrops decreased. The capability of phosphogypsum to supply sufficient electrolytes to inhibit dispersion during storms depends on the amount, intensity, and duration of rainfall of preceding storms (Stern et al., 1991). Agassi et al. (1985) reported that phosphogypsum reduced runoff by 76% compared

with control treatments, even after 528 mm of rainfall. In another study, beneficial effects lasted until the cumulative rain exceeded 700 mm (Stern et al., 1991). This long lasting effect is partially due to return of some of the gypsum to the soil surface through capillary rise during drying periods.

Soil loss increases with increased slope gradient. Runoff and soil loss has been reported to be less in phosphogypsum amended versus control treatments when the slope gradient increased (Agassi et al., 1985, 1989; Warrington et al., 1989). The difference in runoff between the phosphogypsum and the control treatments decreased as the slope increased. Apparently, the greater amount of erosion on control plots removed seal material which led to enhanced infiltration and decreased runoff as the slope increased (Agassi et al., 1985; Warrington et al., 1989).

A single, broadcast application of phosphogypsum at 5 t ha^{-1} was considered to be the most effective amendment in terms of water use efficiency; although a phosphogypsum broadcast at a rate of 10 t ha^{-1} resulted in the greatest cumulative infiltration and final infiltration rate. The effectiveness of phosphogypsum in preventing crust formation is reduced when it is incorporated; however, broadcasting phosphogypsum as a fine powder may expose it to wind erosion (Agassi et al., 1985).

Phosphogypsum has been compared to other amendments and agronomic practices designed to improve soil physical properties. Mulching with corn stover (3 t ha^{-1}) (Stern et al., 1991), straw (80% cover) (Frenkel et al., 1989a), and spray applications of polyacrylamide solution helped prevent physical disintegration of aggregates and were found to be more effective for controlling runoff than was phosphogypsum. The combined application of phosphogypsum and polyacrylamide had a synergistic effect on reducing runoff (Smith et al., 1990; Stern et al., 1991). Phosphogypsum was more effective in reducing runoff and erosion in potato fields than a diked furrow tillage treatment (Agassi et al., 1989). Fuel consumption, an indication of the ease of tillage, was reduced for disking and weeding operations following a 7.5 t ha^{-1} application of phosphogypsum (McKenzie and So, 1989b).

6. Environmental concerns related to the agricultural use of phosphogypsum

6.1. Radionuclide uptake by plants and radioactive buildup in soil

Radionuclides have been reported to be taken up by agricultural plants from soil contaminated by uranium processing wastes (Tracy et al., 1983) and mined phosphate lands (Guidry et al., 1986, 1990); hence, there is some concern that the application of phosphogypsum to agricultural lands may result in the uptake of radionuclides by food crops. Radionuclide uptake is influenced by soil factors and the type of plant species. Root crops, leafy vegetables and legumes tend to take up more radionuclides than fruit bearing plants (Tracy et al., 1983; Guidry, 1986).

Only a few studies have reported the radionuclide uptake by plants grown on phosphogypsum amended soils. May and Mordvedt (1986) applied up to 112 mg ha^{-1} of phosphogypsum containing 925 Bq kg^{-1} of Ra-226 to soil which was used to grow corn, wheat, and soybeans in rotation. No increases in grain Ra-226 were detected in any of the crops, although levels in the surface soil were increased from 35 Bq kg^{-1} to 73 Bq kg^{-1}. Arkhipov et al. (1984) found that rates up to 20 t ha^{-1} increased soil levels of radionuclides, but uptake and accumulation of radionuclides in wheat grain was only slightly higher than in control treatments. In another study, radioactivity determinations of sugarcane juice showed no significant difference in counts among background, control, and phosphogypsum treated areas (Golden, 1983). Relatively low application rates ($<$293 kg ha^{-1}) had little, if any, effect on Ra-226 and Po-210 levels in forage and soil samples (Mullins and Mitchell, 1990). Radium-226 and Pb-210 have been found to be significantly increased in plants grown on reclaimed phosphate mine lands (Guidry et al., 1990). However, the total radionuclide content in the root zone of these soils was at least an order of magnitude greater than what would be contained in a very heavy phosphogypsum application (i.e., 100 t ha^{-1}). It was estimated in the study by Guidry et al. (1990) that a person who obtained all of his or her leafy

vegetables, root vegetables, peas and beans from the phosphate mined lands would receive an effective dose equivalent of 19.1 mrem/year which is not considered to be a health hazard.

A few authors have conducted theoretical radiological assessments of radionuclide buildup in soil and uptake by plants from phosphogypsum applications. Lindeken (1980) described a scenario where phosphogypsum of 0.56 Bq g^{-1} Ra-226 content was applied to soil at an initial rate of 10 tons $acre^{-1}$ followed by alternate year applications of 5 tons $acre^{-1}$. If all the Ra-226 remained in the surface 6 inches, the proposed federal concentration limit of 0.19 Bq g^{-1} soil (federal concentration limit to lands contaminated by uranium tailings on which residences may be constructed) would not be reached for 100 years. Assuming a concentration ratio (radium in dry foodstuff to radium in soil) of 0.01 for crops growing on land containing 0.19 Bq Ra-226 g^{-1} soil, and assuming human consumption of 80 g day^{-1}, the integrated 50-year radiation dose to the bone would be 1.4 rem. The allowable annual dose for unrestricted persons is approximately 2 rem (Lindeken, 1980). It should be noted that the National Council of Radiation Protection (NCRP, 1984) guideline for restricting soil for the use of growing human food crops is a Ra-226 content of 1.5 Bq g^{-1} soil.

Roessler (1988) conducted a detailed radiological assessment to evaluate the extent to which the radioactivity originating from phosphogypsum applied to soil would appear in crops and contribute to human radiation exposure. In one scenario, phosphogypsum containing 1.1 Bq g^{-1} Ra-226 was applied at a rate of 1 ton $acre^{-1}$ once every 4 years and tilled to a depth of 15 cm. Assuming a 2% loss of Ra-226 from the root zone per year by erosion or leaching the equilibrium application concentration would be 0.014 Bq g^{-1}, which would be 90% of that attained after 100 years. Roessler (1988) assumed a very conservative concentration ratio of 1 but placed an upper concentration of 9 Bq Ra-226 kg^{-1} grain dry matter based on earlier observations with other Ra-226 bearing materials. Typical values for U.S. grain products are 0.081–0.093 Bq kg^{-1} (McDowell-Boyer et al., 1979). A person whose sole source of consumed grain products originating from food grown on phosphogypsum-treated land would consume approximately 1.9 Bq day^{-1} of Ra-226 and would receive a bone surface dose of 300 mrem $year^{-1}$ and a committed effective dose equivalent (CEDE) of 20 mrem $year^{-1}$. This intake level is about 50 times greater than the typical dietary uptake and 2.5 times greater than the Federal Radiation Council guidance. The 20 mrem $year^{-1}$ CEDE is 20% of the NCRP recommendation for continuous exposure to an individual of the general public. Roessler (1988) went on to say that these projected intakes and doses are significant but are probably overestimated because it is unlikely that total grain product intake would originate from phosphogypsum treated land. Also, high values were chosen with respect to Ra-226 concentration in plants, intake and dose. It was concluded that the proposed application of phosphogypsum to soil used for grain production would not pose a problem for tens of years although it would be difficult to extrapolate beyond 50 years because some factors were not well defined.

One important factor in the use of phosphogypsum on agricultural lands is the possibility of raising the overall radioactivity of the soil such that it becomes unsuitable for other uses. Thus, even though crops may be consumed from lands treated with phosphogypsum, the land may become unsuitable for residential use due to the potential radon risk in basements. Lindeken (1980) determined that a Ra-226 concentration of 0.19 Bq g^{-1} soil would generate radon daughter concentrations which exceed proposed guidelines for residential occupancy. May and Mordvedt (1986) raised soil Ra-226 from 0.035 to 0.073 Bq g^{-1} after one heavy application of phosphogypsum, thus a few more applications at these high rates would likely result in the guideline levels being exceeded. Recently the U.S. E.P.A. ruled that phosphogypsum would only be permitted for use in agriculture if the average concentration of Ra-226 in the phosphogypsum does not exceed 370 Bq kg^{-1} (Federal Register, 1992). This limit was set to assure that the risks due to indoor radon and direct gamma radiation in residences constructed on land previously treated with phosphogypsum do not exceed an acceptable level.

6.2. Non-radioactive element uptake by plants

The potential uptake of fluoride and trace elements derived from phosphogypsum are potential environmental concerns. Phosphogypsum applications of 10 or 20 t ha^{-1} did not result in accumulation of high fluoride concentrations in soil and plants (Petrov and Savchenko, 1986). Even if phosphogypsum application rates are large enough to cause high fluoride concentrations in the soil, some acid soil studies have shown or suggested that most of the fluoride would be adsorbed in the topsoil (Shainberg et al., 1989; Alva et al., 1990). Few studies have examined heavy metal uptake by plants from phosphogypsum treated soil. May and Mortvedt (1986) reported that very high rates of phosphogypsum application did not have any effect on Cd uptake in a corn-wheat-soybean cropping sequence, however, the Cd concentration of the phosphogypsum was only 0.23 $\mu g\ g^{-1}$. Typical soil levels are 0.35 $\mu g\ g^{-1}$ (Sposito, 1989).

6.3. Other concerns

Phosphorus contamination of surface waters as a result of land application of phosphogypsum is also a concern regarding the agricultural use of phosphogypsum. The results of a laboratory rainfall simulator study suggested that application of high phosphogypsum rates may result in P being exported into waterways adjacent to the sites of application and hence it may contribute to the enhanced eutrophication of the waterways (Korentajer et al., 1991).

7. Conclusions

Very large quantities of phosphogypsum have been produced world-wide since the 1950s because of the high demand for phosphate fertilizer, and because the wet phosphoric acid process produces about 5 tonnes of phosphogypsum for every tonne of phosphoric acid manufactured. Most of the phosphogypsum produced world-wide is stockpiled. Much interest has focused on finding uses for this by-product, such as a soil amendment for the remediation of problem soils. There are still unanswered questions about the environmental implications associated with the storage and agricultural use of phosphogypsum.

The main environmental concerns related to the storage and agricultural use of phosphogypsum are summarized in Fig. 3. Research has determined that acidity, F^-, SO_4^{2-}, certain trace elements and certain radionuclides may be elevated in the waste product and have the potential to be mobile in the environment. Both the acidic process water and the phosphogypsum itself are potential sources of contamination. Much concern is related to the possible contamination of groundwater under phosphogypsum stacks, and to radon exhalation which may pose a health risk to people working on or living close to a stack. Atmospheric F^- can be a significant contaminant from phosphate fertilizer manufacturing; however, most process plants use scrubbers to reduce gaseous F^- levels to within acceptable levels. Some authors predict that employees working on phosphogypsum stacks are at low risk from direct gamma radiation originating from the stacks, or from inhalation of phosphogypsum dust under normal weather conditions. The largest concern related to the use of phosphogypsum as an amendment to agricultural soils is not plant uptake of radionuclides but the risk of elevated indoor radon levels if the agricultural land is later converted to residential usage. For this reason the U.S. E.P.A. has ruled that no phosphogypsum may be used as a soil amendment if its Ra-226 content exceeds 370 Bq kg^{-1}.

The leachate chemistry of the radionuclides is of major importance in determining the environmental impact of phosphogypsum. It is generally believed that most Ra-226 in phosphogypsum exists as a sulfate compound in solid solution with Sr and Ba, however, the physical location of Ra-226 is not clearly resolved. Moisset (1988) found distinct crystals very rich in co-crystallized Ra-226, but some Ra-226 might also be present within the small quantities of hemihydrate that are contained in dihydrate phosphogypsum. Further clarification of the chemical form and physical location of Ra-226 in phosphogypsum may help explain its chemical behavior (Rutherford et al., 1994).

Although Ra-226 is considered to be the main source of radioactivity in phosphogypsum, other U-238 series radionuclides may be present in signi-

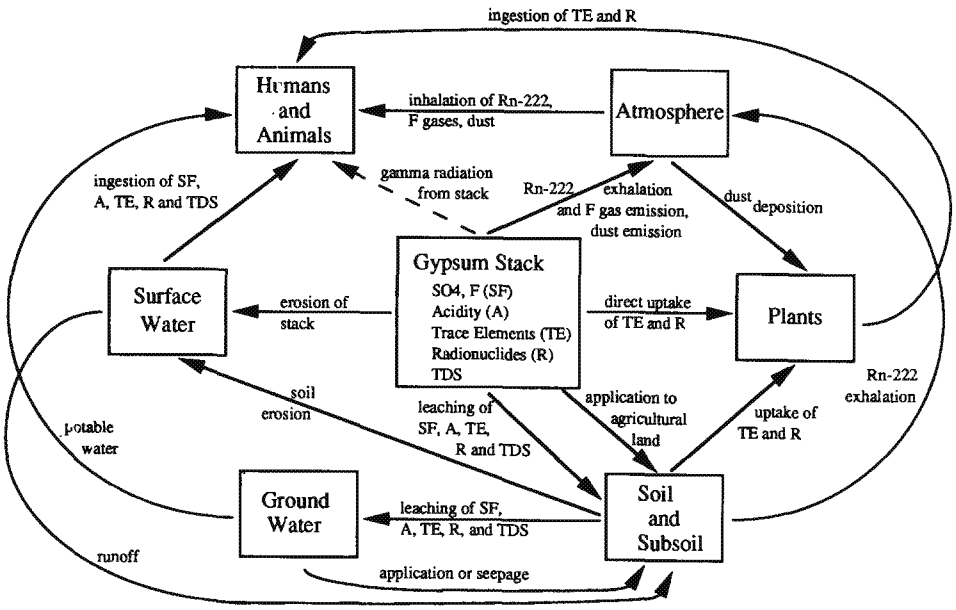

Fig. 3. Main environmental concerns due to the storage and agricultural use of phosphogypsum.

ficant quantities (Table 5). Alpha emitting radionuclides are more of a concern than beta emitters because they do more biological damage once they are inhaled or ingested. Uranium content in phosphogypsum can be quite variable, depending on phosphoric acid plant conditions. Some references have reported U-238 activities equal to that of Ra-226. This is a concern because U(VI) can be highly mobile in the environment. Polonium-210 is a relatively long-lived radionuclide (138 days) which is partitioned into phosphogypsum during the wet phosphoric acid process. Few studies have reported Po-210 chemistry in phosphogypsum, even though it has been found to be the major alpha emitting radionuclide in groundwater under phosphate mined lands. The chemistry of Po-210 is not clearly understood (Upchurch et al., 1991) and therefore requires further investigation. Practices which increase the carbon content and/or biological activity in phosphogypsum, such as the establishment of soil and vegetation caps on stacks, may increase radionuclide mobility due to the production of microbial chelating agents (Birch and Bachofen, 1990). Further research is required to elucidate radionuclide behavior in phosphogypsum and in phosphogypsum-treated soil.

The exhalation of Rn-222 from phosphogypsum stacks may vary by several orders of magnitude, ranging from <0.004 to >3 Bq m^{-2} s^{-1}. Because the U.S. E.P.A. recently adopted an average 0.74 Bq m^{-2} s^{-1} upper limit on Rn-222 emissions from phosphogypsum stacks it is important for companies to monitor their stacks and be aware of the variables which affect Rn-222 exhalation. Most studies have concluded that populations living close to phosphogypsum stacks are not subjected to a significant health risk because air movement readily dilutes Rn-222 concentrations. It is still not clear whether employees who spend numerous hours on active phosphogypsum stacks are subjected to a significant health risk. There is not much published literature on the effects of soil caps and vegetation cover on the release of Rn-222 from phosphogypsum surfaces.

There have been some inconsistent reports

regarding the mobility of phosphogypsum constituents. Some laboratory studies have concluded that significant levels of contaminants do not leach from phosphogypsum, however some field studies have found elevated levels of F^-, SO_4^{2-}, acidity, trace elements, radionuclides and total dissolved solids in groundwater near phosphogypsum stacks. Clearly, further research is required to improve our understanding of the geochemistry occurring within, and beneath, phosphogypsum stacks. To accomplish this it is necessary to identify the solubility-controlling solids of the elements contained within phosphogypsum, especially those for trace elements and radionuclides (Eary et al., 1990). It is also necessary to determine which conditions (e.g. redox, pH and ionic strength) exist within, and beneath, phosphogypsum stacks in order to predict the dominant chemical species present. It is also important to identify the reactions which occur when contaminants originating from phosphogypsum contact soil materials to determine if attenuation occurs before chemical species contact groundwater.

Hi Jon and Andrea,

We are nearing completion of the approval letter and the Federal Register package of materials for the TFI response. I am attaching review copies here for you. **Ex. 5 Deliberative Process (DP)**

Ex. 5 Deliberative Process (DP)

In this email, you have the following:
--Action memo, Edwards to Austin
--FR Notice
--Approval Letter to TFI from Austin
--2 one-page action information sheets necessary as part of a FR package
--FR Typesetting request (just to keep the package in one place, you don't need to do anything with those two PDFs)

Subject: RE: PLEASE READ: SMR Rulemaking and TFI Press Release Discussion with the Regions

Charlene,
Here are some questions regarding the TFI phosphogypsum Press Release/Communication Plan:

- Can you share a copy of the TFI Risk Analysis with the Regions?
    - Generally, how are radon and groundwater risk applied?
    - Is there any comparison in the TFI Risk Analysis for public risk from the material's current state in a stack versus that of a road base? [40CFR61.206(c)] I think the Communication Plan's "Messages" may be misapplying the use of the 3E-4 risk level from the 1992 FR notice in that this risk level was used to derive the radium-226 concentration for agriculture applications in 61.204, but not specifically for "other purposes", i.e. road base.
- The Communication Plan states, "The terms and conditions of the approval also require that EPA be notified in writing prior to the distribution and/or use of phosphogypsum for any government road project. Further, there are road design and construction limitations, site monitoring, record-keeping, public notification, and worker safety requirements included as part of the approval terms and conditions." Who is held as the responsible party if the terms and conditions are not properly followed?

- Assuming the Nuclear Regulatory Commission has determined that phosphogypsum does not meet their regulatory authority of "discreet radium"; wouldn't the phosphogypsum material still be subject to the approval and licensing (or registration) by the State Radiation Program?
- Was the Superfund program consulted? Does the misuse or abandonment of a road project subject the parties to Superfund liability?
- Are there any financial assurance requirements by any parties, if/when a road changes and the road base material is moved or exposed?

Subject: PLEASE READ: SMR Rulemaking and TFI Press Release Discussion with the Regions

Hello all,

We are scheduling a meeting on Monday, October 19, 2020 to discuss the following topics with the Regions:

- SMR Rulemaking – Lee Veal
- TFI Press Release – Jon Walsh/Tom Peake (**Link to Press Release**: https://www.epa.gov/newsreleases/epa-approves-use-phosphogypsum-road-construction)

On the RPP Call on Tuesday, October 20, 2020, we currently have a special guest, Kathy Held, from NCRP presenting on the call; therefore we have decided to have an off schedule meeting with the Regions on **Monday, October 19, 2020 from 2:15pm EST to 3:00pm EST** to allow time to discuss these topics without any time constraints.

Attached to this email you will find the TFI Communications Plan, which has an extensive Q&A, which will probably address some of your questions. If not, in preparation for the meeting on Monday, please send me in advance any questions you may have regarding these topics.

I hope all of you are available to attend the meeting on Monday and I look forward to receiving your questions in advance. Please look for an invite, which will contain the call-in information and the MS Teams link.

If I have mistakenly left someone off of this distribution, please feel free to forward as you find appropriate.

Thank you in advance,
Charlene

Cordially,
Charlene L. Diaz

All,
I think you did a good job with the technical review document. I have a few edits and comments to get at clarity. A couple of comments that may need discussion are below.

Subject: Let's finalize the TFI technical review document and road abandonment document today, no later than Monday

All,
I think the TFI technical review and road abandonment documents are looking really good.

It looks like there is only a little cleanup left so there is not much left to do to finalize them.
Please try to get the last comments in today and go final later today or Monday at the latest.

Thanks.

This is a National FOIA Office Intake Coordination for the above-mentioned FOIA request. A copy of the request is attached. Please review the attachment to determine if the request has enough information for your office to process under the FOIA. Please reply with one of the options below and by filling-in the requested information **no later than 5:00 pm your time on the next working day**.

NFO Preliminary Intake Review

[ ] The request is not reasonably described – clock not started – See Regulations at 40 C.F.R. 2.102(c)
[ ] The request is reasonably described – clock started – request may need additional clarification
NFO Notes: I wasn't sure if OAR or OCSPP would have responsive records for the attached request. Your guidance is appreciated.

FOIA Program Preliminary Intake Coordination (please complete)

1. [ ] **The request is not reasonably described.** My FOIA Program does not have enough information at this time to identify and locate the records. I understand the NFO will schedule a conference call with the FOIA requester. Our Program would like to be a part of the call: YES [ ] or NO [ ]
   - What additional information is necessary to process this request? (e.g. subject matter, date range, internal or external correspondence):
   - If YES, point of contact from your Program to attend the call:
   - If YES, what are the preferred dates and times to attend the call:

2. [ ] **The request is reasonably described**. My FOIA Program has enough information at this time to identify and locate the records.
   a) [ ] Please assign to my FOIA Program - additional clarification may be handled by my program.
   b) [ ] We would like the NFO's assistance in seeking additional clarification. Please stop the clock and schedule a conference call with the FOIA requester. Our Program would like to be a part of the call: YES [ ] or NO [ ]
      - What additional information is necessary to process this request? (e.g. subject matter, date range, internal or external correspondence):
      - If YES, point of contact from your Program to attend the call:
      - If YES, what are the preferred dates and times to attend the call:

3. [ ] **The request does not relate to work in my program.** Please assign to another FOIA Program or agency.
   - Suggested FOIA Program/agency if known:

4. [ ] OPTIONAL: The request can be responded to, **in part,** with **publicly available** or **previously released records**. The records are available at: *[INSERT LINK HERE].* ***If the publicly available or previously released records fully respond to the request, then the Program Office should prepare the close out letter with information to assist the requestor in retrieving the requested records.***
5.
   - [ ] The enclosed records fully respond to the request; *OR*
   - [ ] The enclosed records partially respond to the request.

If you have any questions about this NFO Intake Coordination, please contact me.

Hi Stef,

Ahh, my apologies for the miswording/confusion – I have 9 appendices, plus the Attachment A of Road Specs. Not sure why I lumped them all together.

Just for reference, that attachment is tagged onto this e-mail.

Thanks,

Ray

Hi Ray,

I compared the documents Ray listed as being added to the docket and the items Tony has posted to our supporting documents page. It looks like all documents listed on our web page have also been queued up to be on the docket. I only have one question:

Tony & Ray: Is there an additional TFI appendix? Ray mentioned 10 are in the docket. Our website has 9.

Hi all,

All supporting documentation I've received (a total of 15 documents – the PG Risk Assessment Review [plus 10 appendices], the April TFI petition, 1992 BID, memo for road abandonment, and signed letter from the Administrator) has been processed and uploaded into the docket. Again, the number in regulations.gov is:

EPA-HQ-OAR-2020-0442

As Jon sent out to us, the FR will be published on 10/20. That's plenty of time for the docket staff to do their final QA, so there should not be any issues.

Let me know if I've missed anything or if there are any additional docs we need to have in there in the meantime.

Thanks again all,

Ray

IAEA SAFETY STANDARDS AND RELATED PUBLICATIONS

IAEA SAFETY STANDARDS

Under the terms of Article III of its Statute, the IAEA is authorized to establish or adopt standards of safety for protection of health and minimization of danger to life and property, and to provide for the application of these standards.

The publications by means of which the IAEA establishes standards are issued in the **IAEA Safety Standards Series**. This series covers nuclear safety, radiation safety, transport safety and waste safety. The publication categories in the series are **Safety Fundamentals**, **Safety Requirements** and **Safety Guides**.

Information on the IAEA's safety standards programme is available at the IAEA Internet site

http://www-ns.iaea.org/standards/

The site provides the texts in English of published and draft safety standards. The texts of safety standards issued in Arabic, Chinese, French, Russian and Spanish, the IAEA Safety Glossary and a status report for safety standards under development are also available. For further information, please contact the IAEA at PO Box 100, 1400 Vienna, Austria.

All users of IAEA safety standards are invited to inform the IAEA of experience in their use (e.g. as a basis for national regulations, for safety reviews and for training courses) for the purpose of ensuring that they continue to meet users' needs. Information may be provided via the IAEA Internet site or by post, as above, or by email to Official.Mail@iaea.org.

RELATED PUBLICATIONS

The IAEA provides for the application of the standards and, under the terms of Articles III and VIII.C of its Statute, makes available and fosters the exchange of information relating to peaceful nuclear activities and serves as an intermediary among its Member States for this purpose.

Reports on safety and protection in nuclear activities are issued as **Safety Reports**, which provide practical examples and detailed methods that can be used in support of the safety standards.

Other safety related IAEA publications are issued as **Radiological Assessment Reports**, the International Nuclear Safety Group's **INSAG Reports**, **Technical Reports** and **TECDOCs**. The IAEA also issues reports on radiological accidents, training manuals and practical manuals, and other special safety related publications.

Security related publications are issued in the **IAEA Nuclear Security Series**.

The **IAEA Nuclear Energy Series** consists of reports designed to encourage and assist research on, and development and practical application of, nuclear energy for peaceful uses. The information is presented in guides, reports on the status of technology and advances, and best practices for peaceful uses of nuclear energy. The series complements the IAEA's safety standards, and provides detailed guidance, experience, good practices and examples in the areas of nuclear power, the nuclear fuel cycle, radioactive waste management and decommissioning.

FOREWORD

The Fundamental Safety Principles (IAEA Safety Standards Series No. SF-1), together with Radiation Protection and Safety of Radiation Sources: International Basic Safety Standards (IAEA Safety Standards Series No. GSR Part 3 (Interim)), set out the principles and basic requirements for radiation protection and safety applicable to all activities involving radiation exposure, including exposure to natural sources of radiation. The Safety Guides on Occupational Radiation Protection in the Mining and Processing of Raw Materials (IAEA Safety Standards Series No. RS-G-1.6) and Management of Radioactive Waste from the Mining and Milling of Ores (IAEA Safety Standards Series No. WS-G-1.2) provide guidance on the control of exposure of workers and members of the public to naturally occurring radioactive material (NORM) in industrial activities involving the exploitation of minerals. This guidance applies irrespective of whether the minerals are exploited for their radioactivity content. The phosphate industry constitutes one of several industry sectors for which the radioactivity content of the minerals and raw materials involved is large enough to warrant consideration by the regulatory body concerning the possible need to control exposures of workers and members of the public.

This Safety Report has been developed as part of the IAEA's programme to provide for the application of its safety standards in the field of radiation, transport and waste safety. It is a compilation of detailed information on the processes and materials involved in the phosphate industry and on the radiological considerations that need to be taken into account by the regulatory body when determining the nature and extent of radiation protection measures to be taken. This is consistent with the graded approach to regulation, in terms of which the application of the requirements of the safety standards is commensurate with the characteristics of the practice or source and with the magnitude and likelihood of the exposures.

This Safety Report was drafted in nine consultants' meetings held between 2002 and 2011. Particular acknowledgement is paid to the contributions made by B.K. Birky, J. Hilton and R. García-Tenorio. The IAEA officers responsible for the preparation of this report were D.G. Wymer and P.P. Haridasan of the Division of Radiation, Transport and Waste Safety.

EDITORIAL NOTE

Although great care has been taken to maintain the accuracy of information contained in this publication, neither the IAEA nor its Member States assume any responsibility for consequences which may arise from its use.

The use of particular designations of countries or territories does not imply any judgement by the publisher, the IAEA, as to the legal status of such countries or territories, of their authorities and institutions or of the delimitation of their boundaries.

The mention of names of specific companies or products (whether or not indicated as registered) does not imply any intention to infringe proprietary rights, nor should it be construed as an endorsement or recommendation on the part of the IAEA.

1. INTRODUCTION

1.1. BACKGROUND

Phosphorus is an essential component of all living systems, such as nervous tissue, bone and cell protoplasm. Phosphorus is highly reactive and, therefore, is not found as a free element in nature. It occurs principally in rock deposits containing various mineralized forms of calcium phosphate, $Ca_3(PO_4)_2$, from which commercial phosphate, a non-substitutable, non-renewable resource, is derived on a large scale. The production of phosphate fertilizers and animal feeds constitutes the major commercial activity in the phosphate industry. Phosphorus compounds are also used in a wide variety of food, pharmaceutical, industrial and domestic products.

Phosphate deposits contain the naturally occurring radionuclides ^{238}U and ^{232}Th together with their decay progeny, more details of which are given in Appendix I. From the 1950s to the late 1990s, uranium was recovered as a commercial product in some phosphate processing facilities. Regardless of whether or not the ore has potential for uranium recovery, the presence of these radionuclides of natural origin creates a potential need to control exposures of workers and members of the public in accordance with IAEA safety standards (the Standards), in particular the Fundamental Safety Principles [1], Radiation Protection and Safety of Radiation Sources: International Basic Safety Standards (the BSS) [2], the Regulations for the Safe Transport of Radioactive Material [3] and other relevant Safety Guides [4, 5]. In some process materials, the activity concentrations of radionuclides in the ^{238}U decay series are such that, in terms of the Safety Guide on Application of the Concepts of Exclusion, Exemption and Clearance [6], these materials would be considered for inclusion within the scope of regulation, as naturally occurring radioactive material (NORM).

The Safety Report on Assessing the Need for Radiation Protection Measures in Work Involving Minerals and Raw Materials [7] confirms that the phosphate industry constitutes one of several minerals related industry sectors for which some of the processes involved may warrant radiation protection measures through the system of regulatory control for practices. Reference [7] emphasizes the particular relevance of the graded approach to regulation to ensure that any radiation protection measures applied to the industrial processes involved and to the management of NORM residues arising from those processes are commensurate with the characteristics of the operation and with the magnitude and likelihood of the exposures. This implies the need for a thorough understanding of all the processes, the process materials, the associated

ED_005285_00000684-00015

radiological risks to workers and to members of the public, and the practicalities of any protective measures that need to be considered.

Radioactivity in phosphate deposits has been a subject of study since the early 1900s, at which time it was already known that phosphate deposits contain uranium in concentrations that can be sufficiently high to be of potential value [8, 9]. The mining of phosphate ore, the processing of it into intermediate and end products and the handling and use of those products can all give rise to exposures of workers and members of the public. Residues associated with phosphate processing may also give rise to exposures. When phosphate rock is digested with acid to produce phosphoric acid (the primary starting point for the manufacture of several major phosphate products), some of the radionuclides, particularly isotopes of radium, become concentrated in residues, such as the scale that tends to form inside pipes and vessels. In high temperature processes, radioactive isotopes of the more volatile elements polonium and, to a lesser extent, lead become concentrated in the fume.[1] Hence, from a radiation protection point of view, process residues are potentially of greater concern than the feedstocks and products.

The production of phosphoric acid, phosphate fertilizer and phosphate animal feed can give rise to risks to human health and to the environment from non-radioactive constituents, notably fluorides and heavy metals, such as arsenic, cadmium, lead and mercury. In sufficient concentrations, fluorides can be toxic and environmentally detrimental. They may have to be removed from phosphoric acid and recovered as fluosilicic acid, which has no significant radioactivity content and is used in such applications as water fluoridation. In some instances, phosphate products may require appropriate management to ensure that the public and the environment are adequately protected against exposure to these non-radiological constituents. Radiological considerations are usually of secondary importance but may also have to be taken into account. A particular example in this regard is phosphogypsum, a co-product of phosphoric acid production that, because of the very large amounts involved, is stored in above-ground engineered containments known as 'stacks', often for indefinite periods, or is sometimes disposed of in surface water bodies such as estuaries and the sea. Best practices established for the management of non-radiological risks to humans and to the environment have generally proven to be effective in minimizing any risks arising from the residual radioactivity content. Nevertheless, the radioactivity aspect continues to arouse public concern in some countries.

---

[1] The term 'fume' in this context denotes the vapour and/or suspended fine dust particles released from a high temperature industrial process.

ED_005285_00000684-00016

1.2. OBJECTIVE

The objective of this Safety Report is to provide detailed information that will assist regulatory bodies and industry operators in implementing a graded approach to the protection of workers and of members of the public against exposures arising from the processes and products associated with the phosphate industry. The information provided in this Safety Report will also serve as the basis for creating a common understanding, based on common knowledge, between the various stakeholders in the production of phosphate products, including the primary producers (the phosphate industry) and the regulatory bodies involved.

1.3. SCOPE

This Safety Report provides practical information on the radiological risks to workers and to members of the public in the production and use of phosphate based products, their assessment and their management based on the application of the appropriate Standards and good working practices. This information has been compiled from published literature, from unpublished data provided by contributors to this report and from numerous experts with extensive experience, notably in the various sectors of the phosphate industry. The report describes the basic industrial processes associated with the phosphate industry, from the mining of phosphate ore to the production and use of phosphate fertilizers, animal feeds, phosphogypsum and other products. For each process, the radiological parameters of the raw materials, products and residues are quantified, as well as the exposure levels for workers and for members of the public. The data are used as the basis for determining, in principle, the need for, and extent of, regulatory control to ensure that the requirements of the Standards for each aspect of the industrial processes involved are met. Information is provided on monitoring and dose assessment techniques, measures taken to reduce doses, the transport and storage of bulk raw materials and the management of the various waste streams. The report covers both routine operations and non-routine operations such as plant maintenance, decommissioning and decontamination.

1.4. STRUCTURE

Following this introduction, Section 2 provides an overview of the phosphate industry, covering the early history of phosphate fertilizer production, a description of phosphate resources, processes and products and a review of

ED_005285_00000684-00017

recent trends worldwide. Section 3 summarizes the radiation protection considerations that apply to NORM industries in general and the phosphate industry in particular, including the application of the Standards, the main exposure pathways involved, the monitoring of exposed workers and dose assessment, as well as providing an example of radionuclide migration during various stages of phosphate processing. Section 4 deals with the mining and beneficiation of phosphate ore, beginning with a description of the processes and process materials involved (including, in particular, the radionuclide concentrations), followed by data on the exposure of workers and members of the public and concluding with a discussion of the regulatory implications. This basic reporting structure — process description, radionuclide concentrations, occupational and public exposure, and regulatory considerations — provides a common framework for the sections that follow, starting with the production of phosphoric acid by acid digestion (Section 5) and then moving on to the manufacture and use of ammonium phosphate fertilizer (Section 6), superphosphate fertilizer (Section 7), nitrophosphate fertilizer (Section 8) and animal feed phosphates (Section 9). The storage, use and disposal of phosphogypsum, a co-product of phosphoric acid production, give rise to a variety of radiological (and non-radiological) considerations, and these are covered in Section 10. The decommissioning of plant and the recycling or disposal of contaminated scrap arising from maintenance or decommissioning are discussed generically in Section 11, the radiological considerations being, in principle, common to all the 'wet' chemical processes covered in the preceding sections. Recently, there has been a revival of interest in two additional processes in the phosphate industry that had fallen from favour over the years. These are the extraction of uranium from phosphoric acid, which is addressed in Section 12, and the production of elemental phosphorus by the thermal processing of phosphate rock, which is addressed in Section 13. Additional, more detailed, technical information is presented in six appendices covering the following topics: (i) radionuclides in the ^{238}U and ^{232}Th decay series, (ii) the composition of phosphate ores, (iii) phosphate products and their uses, (iv) the composition of (beneficiated) phosphate rock, (v) methods for converting phosphate rock into phosphoric acid using sulphuric acid attack and (vi) the composition of phosphogypsum. Finally, some additional information is provided in two annexes, one summarizing the particle size characterization of airborne dust in a phosphoric acid plant and related dissolution studies and the other describing the remediation of a coastal and marine phosphate residue deposit.

ED_005285_00000684-00018

2. OVERVIEW OF THE PHOSPHATE INDUSTRY

2.1. EARLY PHOSPHATE FERTILIZER PRODUCTION

The production of phosphate fertilizer has always been the primary activity of the phosphate industry and accounts for the vast majority of global phosphate production. Phosphate fertilizer technology was initially very simple. The use of dilute sulphuric acid was introduced to Bohemia in 1831 to convert biogenic phosphate in the form of bones and coprolites[2] to a largely water soluble form. The product was called superphosphate, a term already used by chemists and apparently first used as early as 1797 by the British physician George Pearson to describe the phosphate compound calcium dihydrogenphosphate ($Ca(H_2PO_4)_2$) found in bone. In 1840, Justus von Liebig made a historic address before the British Association of Science in which he gave a clear exposition of the role of minerals in plant growth and laid the groundwork for modern agricultural science. He was the first to demonstrate scientifically that insoluble phosphates such as bone could be made to release their phosphorus in a form more quickly available to growing plants if they were caused to react with sulphuric acid. That suggestion stimulated John Bennett Lawes to treat coprolites with sulphuric acid and to test the resultant phosphate as a plant nutrient. (Coprolites were a fairly abundant source of phosphorus in the United Kingdom at that time.) In 1842, Lawes was granted a patent on this idea, which permitted him to establish the first commercial superphosphate works. Within 20 years, the United Kingdom was producing 150 000 t of superphosphate per year [10].

In the early stages of the industry, bones from European battlefields, along with cattle bones from the Russian Federation and South America, were popular sources of biogenic phosphates. Surging demand for phosphate led to the extensive export from Peru of guano, a rich source of phosphate. The rapid growth of world demand for phosphate in the 1850s severely depleted these known resources of bones, coprolites and guano [11–13].[3] It was the exhaustion of these and other biogenic sources of supply that acted as a catalyst to the emergence of the modern phosphate industry. The supply of phosphate was eventually secured by the discovery of large sedimentary phosphate deposits, known as phosphorite, in South Carolina, United States of America. Mining began in 1867. By 1870, several deposits of phosphorite were being exploited to supply rock to the growing superphosphate industries of Europe and America and

[2] Coprolites are fossilized animal faeces.

[3] By 1851, the United Kingdom was the major importer of bones for bone meal.

ED_005285_00000684-00019

bones and coprolites were rapidly supplanted. The estimated market value had grown by that time to some £8 million (1870s values) [14]. By 1889, the South Carolina mine was supplying 90% of the worldwide phosphate industry. At about the same time, prospecting was active in Florida, United States of America, in the search for new sources of commercially exploitable rock [13].

2.2. PHOSPHATE RESOURCES

Phosphate deposits contain calcium and phosphorus, essentially as tricalcium phosphate, $Ca_3(PO_4)_2$, and fall into five major categories:

(i) Sedimentary marine deposits;
(ii) Igneous (magmatic) deposits;
(iii) Metamorphic deposits;
(iv) Biogenic deposits, mainly accumulations of bird and bat guano;
(v) Deposits caused by weathering.

Most phosphate deposits are of a single type, although a few, including some recent discoveries, are mixtures of sedimentary and igneous types. Sedimentary marine deposits account for the majority of worldwide phosphate production [15]. This market dominance is expected to continue in the future. Such deposits originate from the sedimentation of bones of fish and marine mammals and are normally found in layers. Being of animal origin, they commonly contain impurities because non-phosphate components of animal bodies are also deposited with the phosphate-containing portions. Some very old marine deposits are associated with fossils [12]. Igneous deposits, which account for most of the remaining worldwide phosphate production, are created by magmatic extrusion in the form of an alkaline chimney, usually with a roughly circular cross-section, and are relatively inhomogeneous. They tend to contain fewer impurities than sedimentary phosphates and are generally free of organic material.

Phosphate ores contain one or more phosphate minerals suitable for commercial use, such as calcium fluophosphate. The mineralogy of phosphorus rich rocks is complex and there are more than 200 known phosphate minerals. The main mineral group is the apatite group of calcium phosphates having the general chemical formula $Ca_{10}(PO_4,\pm CO_3,\pm OH)_6(OH,F,Cl)_2$. The exact chemical composition varies with origin. Apatites are found mainly in sedimentary, metamorphic and igneous rocks and include fluorapatite, hydroxyapatite, carbonate-hydroxyapatite and francolite.

ED_005285_00000684-00020

Fluorapatite is described by the chemical formula $Ca_{10}(PO_4)_6F_2$ (alternatively expressed as $3Ca_3(PO_4)_2 \cdot CaF_2$) or $Ca_{10}(PO_4)_6(F,OH)_2$. It is found mainly in igneous and metamorphic environments, such as in carbonatites and mica pyroxenites. Pure fluorapatite contains 42% P_2O_5.[4]

Hydroxyapatite is described by the chemical formula $Ca_{10}(PO_4)_6(OH)_2$. It is found mainly in igneous and metamorphic environments but also in biogenic deposits such as bone deposits.

Carbonate-hydroxyapatite is described by the chemical formula $Ca_{10}(PO_4,CO_3)_6(OH)_2$ or $Ca_{10}(PO_4)_{6-x}(CO_3)_x(OH)_{2+x}$. It is found mainly on islands and caves as part of bird and bat excrement (guano).

Francolite is a commonly occurring complex carbonate-fluorapatite that exhibits several kinds of ionic substitution, principally CO_3F^- for PO_4^{3-} (which therefore reduces the phosphate content), Na^+ and Mg^+ for Ca^{2+} and perhaps OH^- for F^- [16]. Francolite has been described as two similar but distinct compounds [17] that may be represented in a consolidated form by the chemical formula $Ca_{10-a-b}Na_aMg_b(PO_4)_{6-x}(CO_3)_xF_yF_2$ where a = x–y and x = 0–1.5. The formula $Ca_{10-x-y}Na_{2x}Mg_y(PO_4)_{6-z}(CO_3)_zF_2F_{0.5z}$ has also been suggested. Francolite is found mainly in marine sedimentary environments and, to a much lesser extent, in weathered environments such as those covering carbonatites.

2.3. PHOSPHATE PRODUCTION AND RESERVES

Total global phosphate deposits are estimated to be 163 billion t. Most of these deposits are of sedimentary origin, with as little as 4% being of igneous origin [12]. Phosphatic materials are usually characterized in terms of their P_2O_5 content. This is done as a convenience and not as a strict chemical description. Phosphate ores generally have P_2O_5 contents in the range 4–40%. The fluorine content, which is associated principally with fluorapatite and francolite, varies from less than 1% to more than 4% and can be of concern if allowed to find its way into phosphate animal feed products or into the environment. Small amounts of heavy metals, which are potentially harmful to human health, are also found in phosphate ores. More detailed data on the composition of phosphate ores are given in Appendix II.

The concept of exploitability of phosphate deposits is subject to constant redefinition as mining and beneficiation techniques and technologies evolve, partly in response to market forces. A number of economic and technical factors

[4] Throughout this report, the percentage values used for quantifying chemical composition refer to weight per cent.

ED_005285_00000684-00021

influence quite significantly the calculation of phosphate reserves, not least the cost of processing rock with a relatively low phosphate content. For a phosphate deposit to be considered viable, the phosphate mineral component of the ore (that is, the phosphate rock remaining after removal of the barren material) must have a P_2O_5 content above a certain minimum value. The determination of this minimum value tends to be based on the suitability of the phosphate rock for digestion with acid to produce marketable phosphoric acid (the strength of which needs to be at least 28% P_2O_5). Historically, phosphate rock needed to have a minimum P_2O_5 content of 27–30%, but changes in manufacturing practice are now enabling some phosphate deposits to be categorized as ore reserves if the phosphate rock component has a minimum P_2O_5 content of 23% and, in some cases, even less [18]. Owing to the fact that early scientific research into phosphate recovery was conducted on bones, it is still common for the phosphate content of phosphate rock to be expressed in terms of a 'bone phosphate of lime' (BPL) number, where a BPL of 1 represents a P_2O_5 concentration of 0.4576%. Thus, phosphate rock with a P_2O_5 content of 30% (a typical value for commercial production of phosphoric acid) has a BPL of 66.

A breakdown of worldwide phosphate production and reserves, as reported in Ref. [19], is given in Table 1. In 2010, China, Morocco and the USA together accounted for almost two thirds of worldwide mining production of phosphate rock. The USA was historically the world's largest producer but was overtaken by China in 2006–2007. This was symptomatic of a more general trend towards increased phosphate mining outside the USA. At the same time, mining within the USA has been decreasing as a result of the combined effects of pricing policies and local public opposition to mining, especially in Florida, where most of the mining takes place. In 2008, Morocco announced that, in response to surging demand, it was planning to double its mining production, putting it within reach of becoming the future global leader in phosphate mining production.

2.4. PROCESSES AND PRODUCTS

Phosphate ore is converted into commercial products using the following three main process steps:

(i) After being mined, phosphate ore is beneficiated to produce a concentrate known as phosphate rock (also known as beneficiated phosphate rock or phosphate rock concentrate).
(ii) According to Ref. [20], as much as 85% of the phosphate rock produced in step (i) is converted into intermediate or final products using a process of

ED_005285_00000684-00022

TABLE 1. PRODUCTION AND RESERVES OF PHOSPHATE ROCK (BY COUNTRY) [19]

Country	Estimated mine production in 2010 (million t)	Reserves (million t)
China	65	3700
USA	26.1	1400
Morocco and Western Sahara	26	50 000
Russian Federation	10	1300
Tunisia	7.6	100
Jordan	6	1500
Brazil	5.5	340
Egypt	5	100
Israel	3	180
Syrian Arab Republic	2.8	1800
Australia	2.8	82
South Africa	2.3	1500
Algeria	2	2200
Togo	0.8	60
Canada	0.7	5
Senegal	0.65	180
Other countries	9.5	620
Total (rounded)	176	65 000

acid digestion known as the 'wet process'.[5] A relatively small amount is converted directly into elemental phosphorus by reduction in an electric arc furnace in a process known as the 'thermal process'. It is estimated that 71% of all phosphate rock produced is processed into phosphoric acid

[5] In some instances, finely ground phosphate rock, sometimes known as 'reactive phosphate rock', is applied directly to soil as a fertilizer, while 'partially acidulated phosphate rock' has been used in Australia and New Zealand, as well as in some developing countries where plant nutrient resources may be both scarce and unaffordable. It is estimated that the phosphate rock used in this manner accounts for only 0.3% of total phosphate rock production [21–23].

ED_005285_00000684-00023

(involving, in most cases, the co-production of large amounts of phosphogypsum), 24% is processed directly into fertilizer (as opposed to indirect processing via phosphoric acid) and the remaining 5% is converted directly into various other products. The annual production of P_2O_5 in the form of phosphoric acid is more than 30 million t.

(iii) Most of the phosphoric acid produced in step (ii) (estimates vary from 75% to 90%) is subjected to further chemical processing to convert it into fertilizer. The fertilizer products so derived from phosphoric acid thus account for some 55–60% of total phosphate rock production. Of the remaining 10–25% of phosphoric acid produced in step (ii), about half is processed into animal feed supplements and half into a variety of other products. The recovery of uranium from phosphoric acid (to which most of the uranium in the ore migrates) was an important activity prior to the slump in world uranium prices in the 1980s and 1990s. With the revival of interest in nuclear power and the depletion of uranium stockpiles, the recovery of uranium from phosphoric acid is set to increase once more.

An aerial view of a complete phosphate fertilizer production facility is shown in Fig. 1. The site illustrates many of the important social and environmental issues associated with such facilities. It is an environmentally sensitive area, close to a growing urban settlement that is gradually encroaching on the site. The facility has been in operation for over 50 years and now includes land recovered from the stockpiling of phosphogypsum. As part of the long term decommissioning process, this land is planned for redesignation as an amenity for the local community. In preparation for release, it has already been successfully replanted with selected native trees and shrubs.

A schematic view of the processes and products involved in the phosphate industry is shown in Fig. 2. An estimate of how the phosphate in the ore (expressed as P_2O_5) is distributed among the various process materials and products is given in Table 2. The amounts have been calculated by piecing together information from various sources and assuming, as a starting point, an annual phosphate rock production of 160 million t with an average P_2O_5 content of about 30% (66 BPL). Owing to changing circumstances and incomplete commercial data, Table 2 conveys only a general impression and is not intended to be definitive. Nevertheless, it can be concluded that some 80% of all exploitable P_2O_5 currently being extracted from the earth by phosphate mining is destined for use in fertilizer, while about 7% ends up in animal feed supplements. The remainder finds its way into a wide variety of products used in the food and beverage industry, in pharmaceutical and household products and in a diversity of industrial applications including:

ED_005285_00000684-00025

TABLE 2. DISTRIBUTION OF THE PHOSPHATE CONTENT OF THE ORE AMONG THE VARIOUS PROCESS MATERIALS AND END PRODUCTS

Material	Estimated amount of material generated annually worldwide (million t)		Exploitable P_2O_5 content as a proportion of that contained in the ore (%)
	Material mass	Mass of exploitable P_2O_5 content	
Ore[a]	530	48	100
Phosphate rock[a]	160	48	100
Tailings	370	0	0
Phosphogypsum	170	1.8	4
DAP fertilizer	41	20	41
MAP fertilizer	8	4.3	9
SSP fertilizer	23	6	13
TSP fertilizer	6	3.4	7
Other fertilizer	—	4.5	9
MCP–DCP animal feed	6	2.7	6
TCP animal feed	1	0.3	1
Other phosphate products	—	5	10

[a] It is recognized that there are significant deficiencies in the extraction of the exploitable content of the rock, leading to estimated losses of up to 30% of the P_2O_5 in the ore prior to beneficiation [24]. For the purposes of this table, these losses are not taken into account.

(a) The manufacture of chemicals, textiles, leather, glass, cement, ceramics, paper, rubber, electronic components and fire retardants;
(b) The treatment and coating of metals;
(c) Foundries;
(d) Water treatment;
(e) Mining and oil well drilling.

Many products comprise phosphates of sodium, potassium, calcium, ammonium and magnesium. A more detailed list of the various products associated with the phosphate industry is given in Appendix II. Products destined for human consumption via food, beverages or pharmaceutical products are required to meet strict purity requirements that limit the concentrations of heavy metals and fluoride, thereby ensuring also that radioactivity levels are well below

ED_005285_00000684-00026

levels of concern. An analysis of a typical product for human consumption (tricalcium phosphate) showed that the radionuclide concentrations were less than 0.05 Bq/g [25]. Consequently, such products are not discussed further in this report.

2.5. RECENT DEVELOPMENTS AFFECTING THE INDUSTRY

Since 2000, a period of intense change has occurred in the phosphate industry. Traditional European centres of manufacture such as those in Greece, Italy and Spain are progressively closing their plants, with a consequential shift of emphasis in regulatory attention from production operations to the management of legacy issues [26–28]. Countries with emerging economies such as Brazil, China and India have markedly increased their demand for fertilizers in general, and phosphates in particular, for food production [29]. Brazil is importing increased amounts of phosphate fertilizer because its production capacity, although growing, is not keeping pace with domestic demand. China, by contrast, has changed from being a net importer to a net exporter as major new capacity has come on stream [20]. India is almost completely reliant on imported phosphates, but does have some low grade phosphate deposits that may be exploited in the future because of their uranium content [30]. New plants are being planned or built in various parts of the world:

(a) In Saudi Arabia, a major new facility at Ma'aden will, in future, become one of the world's single largest production sites.
(b) In Morocco, additional capacity and new joint ventures are being established at Jorf Lasfar, which is set to remain the world's single largest production site for phosphoric acid.
(c) New facilities and extensions to existing capacity are being constructed in many countries, including Algeria, Brazil, China, Egypt, Jordan, Lebanon and the Syrian Arab Republic.
(d) Malawi intends to establish its own phosphoric acid production capability and many other countries are considering entering the market [29].

Such changes have shifted the centre of gravity of the industry away from countries with developed economies, resulting in decreased production levels and fewer facilities in those countries. The shift is towards countries with emerging and developing economies, where expansion of production capacity is more than offsetting the decrease in production elsewhere. At the same time, some major phosphate rock producing countries such as Morocco are now committed to the introduction of 'value added' activities such as chemical processing and

ED_005285_00000684-00027

granulation, leading to a change in their trading patterns from the mining and shipping of phosphate rock to the production and sale of end products in the form of fertilizer and animal feed. The changes have also brought new challenges for those tasked with maintaining safety standards and best practices in the phosphate industry at both national and international levels [31, 32]. For instance:

(a) The transport and use of phosphate products across geographical and regulatory boundaries are increasing.
(b) Phosphoric acid plants that have ceased production have to be decommissioned.
(c) Neglected or abandoned phosphogypsum stacks have to be reincorporated into a formal management process, which may include finding suitable uses for the material to minimize the amount that has to remain in storage on-site.

Three major new factors in world fertilizer markets as a whole are the projected 70% increase in demand for food by 2050 to feed the growing population, the emergence of a demand for biofuels derived from corn and sugar cane and the surge in demand for animal protein. The demands are growing rapidly, with as yet unknown consequences for patterns of fertilizer consumption. In the USA, a political emphasis on renewable sources of energy, notably biofuels, is having a significant impact on the situation.

In addition, wider sustainability objectives such as those associated with greenhouse gas emissions and the conservation of scarce or non-renewable resources are creating a framework within which the historical role of phosphogypsum as a co-product of phosphoric acid production, rather than as a waste, is being reinvigorated. From the outset, phosphogypsum has been an item of commerce in many countries, with a well-established market value in a variety of applications, especially those in agriculture and construction that have the capacity to consume large volumes [33]. In some markets, however, the commercial use of phosphogypsum has been restricted because of concerns about its radioactivity content and, to a lesser extent, its heavy metals content, even though such concerns appear to be without scientific foundation. In the light of the recent global developments described here, the reasons for treating phosphogypsum as a co-product rather than as a waste become more compelling than ever.

ED_005285_00000684-00028

3. GENERAL RADIATION PROTECTION CONSIDERATIONS

3.1. APPLICATION OF THE STANDARDS TO INDUSTRIAL ACTIVITIES INVOLVING EXPOSURE TO NATURAL SOURCES

3.1.1. Scope of regulation

Paragraph 3.4 of the BSS [2] states that exposure to natural sources is generally considered as an existing exposure situation, meaning that the exposure does not fall within the scope of regulation in terms of the requirements for planned exposure situations. However, some industrial activities giving rise to exposure to natural sources have the characteristics of practices and para. 3.4 of the BSS makes provision for the requirements for planned exposure situations to apply in such cases, depending principally on the activity concentrations of radionuclides of natural origin in the material giving rise to the exposure (in this case, any of the process materials involved). The requirements for planned exposure situations apply if the activity concentration of any radionuclide in the uranium or thorium decay chains is greater than 1 Bq/g or the activity concentration of ^{40}K is greater than 10 Bq/g. As a result of this criterion, the phosphate industry is identified in Ref. [7] as being among those industrial activities that are likely to be subject to the requirements for planned exposure situations.[6]

It is important to note that the use of commodities containing radionuclides of natural origin, such as fertilizer, soil amendments and construction materials, is always subject to the requirements for existing exposure situations, regardless of the activity concentrations.

---

[6] These criteria do not apply to radon, existing residues in the environment and commodities such as foodstuffs, drinking water, agricultural fertilizer and soil amendments and construction materials, which are normally treated as existing exposure situations regardless of the activity concentrations of the radionuclides concerned, nor do they apply to material in transport, the criteria for which are specified separately in the Standards (see Section 3.1.3). Exposure of workers to radon is regulated according to the requirements for planned exposure situations if the radon concentration in the workplace remains above the applicable reference level after the implementation of remedial action.

ED_005285_00000684-00029

3.1.2. Graded approach to regulation

Where the activity concentration values specified in Section 3.1.1 are exceeded, a graded approach to regulation as a practice is adopted in accordance with the requirements of the BSS (para. 3.6). The application of the graded approach to the regulation of operations involving exposure to NORM is described in Refs [4, 7] and is summarized in Sections 3.1.2.1–3.1.2.3.

3.1.2.1. Initial assessment

An initial assessment is made of the process, the materials involved and the associated exposures. For industries engaged in the processing of NORM, the exposure pathways to workers and to members of the public that are most likely to require consideration are those involving external exposure to gamma radiation emitted from process material and internal exposure via the inhalation of radionuclides in dust[7]. Consideration of internal exposure via the inhalation of ^{222}Rn and/or ^{220}Rn emitted from process material (leading to exposure to the short lived progeny of these radionuclides) may also be necessary during the exploitation of certain minerals. Internal exposure via ingestion may need to be considered for members of the public (mainly as a result of water pathways) but is unlikely to be of concern for workers under normal operational circumstances.

The assessment of the effective dose received by an individual involves summing the personal dose equivalent from external exposure to gamma radiation over a specified period and the committed equivalent dose or committed effective dose, as appropriate, from intakes of radionuclides over the same period. The assessment method is described in more detail in Ref. [4].

3.1.2.2. Regulatory options

The four basic options open to the regulatory body, in ascending order of degree of control, are as follows:

The regulatory body may decide that the optimum regulatory option is not to apply regulatory requirements to the legal person responsible for the practice. The mechanism for giving effect to such a decision could take the form of an exemption. For exposure to NORM, the exemption criterion given in the BSS [2] is a dose of the order of 1 mSv per year. The background to this criterion is given in Ref. [34], which concludes that exemption is likely to be the optimum option if the material does not give rise to an annual effective dose received by a worker

[7] Dust includes aerosols containing solid and/or liquid particles suspended in air.

ED_005285_00000684-00030

exceeding about 1–2 mSv (this being a small fraction of the occupational dose limit), bearing in mind that the dose received by a member of the public in such circumstances is likely to be lower by at least an order of magnitude [7].

Where the regulatory body has determined that exemption is not the optimum option, the minimum requirement is for the legal person to submit a formal notification to the regulatory body of the intention to carry out the practice. As in the case of a decision to grant an exemption, this is an appropriate option when the maximum annual effective dose is a small fraction of the applicable dose limit, but it provides the added reassurance that the regulatory body remains informed of all such practices and of any changes to such practices that might have significant radiological implications.

Where the level of exposure to NORM is such that neither exemption nor the minimum regulatory requirement of notification is the optimum regulatory option, the regulatory body may decide that the legal person has to meet additional (but limited) obligations to ensure that exposed individuals are adequately protected. These obligations would typically involve measures to keep exposures under review and to ensure that the working conditions are such that exposures remain moderate, with little likelihood of doses approaching or exceeding the dose limit.[8] The mechanism for imposing such obligations on the legal person is the granting of an authorization in the form of a registration [4].

Where an acceptable level of protection can only be ensured through the enforcement of more stringent exposure control measures, an authorization in the form of a licence may be required [4]. This is the highest level of the graded approach to regulation and its use for practices involving exposure to NORM is likely to be limited to operations involving substantial quantities of material with very high radionuclide activity concentrations.

3.1.2.3. Control measures for authorized practices

A detailed account of the control measures that may be appropriate for authorized practices involving work with minerals and raw materials is given in Refs [4, 5]. In terms of the graded approach to regulation, the nature and extent of such measures will be commensurate with the type of practice and the levels of exposure, but will generally entail the establishment of some form of radiation protection programme with suitable provisions for monitoring and dose assessment at a more detailed level than in the initial assessment referred to in Section 3.1.2.1.

---

[8] For situations in which workers are exposed to gamma radiation and radionuclides in inhaled dust, Ref. [34] states that "Control, if considered necessary, would include the use of methods to suppress or contain any airborne dusts and general radiological supervision".

ED_005285_00000684-00031

Specific radiological measures in the workplace, such as control of the occupancy period or even shielding, may sometimes be appropriate to minimize external exposure to NORM. Materials with relatively low activity concentrations give rise to modest gamma dose rates (typically no more than a few microsieverts per hour), even on contact. In such cases, discouraging access, for example by storing materials in mostly unoccupied areas, may be sufficient. In areas containing materials with relatively high activity concentrations, physical barriers and warning signs may be necessary.

Exposure to airborne dust is likely to be controlled already in many workplaces through general occupational health and safety (OHS) regulations. Control of air quality for the purpose of minimizing dust levels may also help to reduce radon and thoron concentrations. Therefore, the extent to which existing OHS control measures are effective in minimizing workers' radiation exposure is something that the regulatory body would first need to establish before deciding to impose additional control measures for purely radiological reasons. In some workplaces, existing OHS control measures alone may provide sufficient protection against internal exposure. In other workplaces, additional control measures specifically for radiation protection purposes may become necessary for achieving compliance with the Standards. Engineered controls are the favoured option, with working procedures and, finally, protective respiratory equipment being considered only where further engineering controls are not effective or practicable.

Complete containment of material is often impractical, especially where large quantities of low activity concentration materials are involved and spills and the spread of materials outside the area are often of no radiological significance unless substantial and persistent airborne dust levels result. Prevention of resuspension of dust is, therefore, likely to be the most effective approach. Specific measures to control surface contamination only become meaningful where materials with higher activity concentrations are present.

Worker awareness and training are particularly important for supporting the introduction of local rules and for creating an understanding of the precautions embodied in such rules. The work practices of individual employees may exacerbate dust generation and, in some cases, may completely negate the effect of any engineering controls installed. There may be deficiencies in the way in which equipment maintenance tasks are undertaken, implying the need for periodic review to determine if improvements are possible. The general standard of 'housekeeping' and spillage control also needs to be kept under regular review. Even where the materials being handled have a low activity concentration, a reasonable standard of housekeeping may be necessary to ensure that dust resuspension is adequately controlled.

ED_005285_00000684-00032

3.1.3. Material in transport

3.1.3.1. Basic criteria

The safety requirements for material in transport are set out in the Regulations for the Safe Transport of Radioactive Material (the Transport Regulations) [3]. The transport of material in its natural or processed state, associated with the phosphate industry, may or may not fall within the scope of the Transport Regulations, depending on the activity concentration of the material.

The Transport Regulations only apply if the activity concentration of the material exceeds 10 times the activity concentration for exempt material.[9] For individual radionuclides of natural origin, the activity concentrations for exempt material are shown in Table 3.

3.1.3.2. Mixtures of radionuclides

For mixtures of radionuclides, the activity concentration for exempt material is:

$$X_{\mathrm{m}} = \frac{1}{\sum_i \frac{f(i)}{X(i)}} \qquad (1)$$

where

X_{m} is the activity concentration for exempt material (in Bq/g);
$f(i)$ is the fraction of activity concentration of radionuclide i in the mixture;
$X(i)$ is the activity concentration for exempt material for radionuclide i (in Bq/g);

and the condition for application of the Transport Regulations (see Section 3.1.3.1) is:

[9] This activity concentration criterion applies only to material containing radionuclides of natural origin that is either in its natural state or has been processed only for purposes other than for the extraction of the radionuclides, and that is not intended to be processed for the use of these radionuclides.

ED_005285_00000684-00033

TABLE 3. ACTIVITY CONCENTRATIONS FOR EXEMPT MATERIAL IN TRANSPORT

Nuclide	Activity concentration (Bq/g)	Progeny included in secular equilibrium
U-238 decay series		
U_{nat} (U-238)	1	Th-234, Pa-234m, U-234, Th-230, Ra-226, Rn-222, Po-218, Pb-214, Bi-214, Po-214, Pb-210, Bi-210, Po-210
U-238	10	Th-234, Pa-234m
Th-234	1000	Pa-234m
U-234	10, 100[a]	None
Th-230	1	None
Ra-226	10	Rn-222, Po-218, Pb-214, Bi-214, Po-214, Pb-210, Bi-210, Po-210
Pb-210	10	Bi-210, Po-210
Po-210	10	None
Th-232 decay series		
Th_{nat} (Th-232)	1	Ra-228, Ac-228, Th-228, Ra-224, Rn-220, Po-216, Pb-212, Bi-212, Tl-208 (0.36), Po-212 (0.64)
Th-232	10	None
Ra-228	10	Ac-228
Th-228	1	Ra-224, Rn-220, Po-216, Pb-212, Bi-212, Tl-208 (0.36), Po-212 (0.64)
Ra-224	10	Rn-220, Po-216, Pb-212, Bi-212, Tl-208 (0.36), Po-212 (0.64)
K-40	100	None

[a] The applicable value depends on the chemical form of the material.

$$\sum_i x(i) > 10X_m \tag{2}$$

where $x(i)$ is the activity concentration of radionuclide i in the mixture.

ED_005285_00000684-00034

Combining Eqs (1) and (2) and making the substitution:

$$f(i) = \frac{x(i)}{\sum_i x(i)} \tag{3}$$

gives the condition for application of the Transport Regulations as:

$$\sum_i \frac{x(i)}{X(i)} > 10 \tag{4}$$

3.1.3.3. Material with decay chains in equilibrium

For material in which the radionuclides in each decay series are (or are deemed to be) in equilibrium, the values of activity concentration for exempt material for U_{nat}, Th_{nat} and ^{40}K (see Table 3) can be used to derive the condition for application of the Transport Regulations, with the progeny of ^{238}U and ^{232}Th automatically being taken into account. Equation (4) then becomes:

$$\frac{x(U_{nat})}{1} + \frac{x(Th_{nat})}{1} + \frac{x(^{40}K)}{100} > 10 \tag{5}$$

For materials that are not particularly rich in potassium, Eq. (5) can be approximated to:

$$x(U_{nat}) + x(Th_{nat}) > 10 \tag{6}$$

3.1.3.4. Material with decay chain segments in equilibrium

The available data on the radionuclide composition of the material may indicate that equilibrium conditions do not prevail throughout the decay chains but that it may be possible to treat the material as a mixture of decay chain segments, each of which can be assumed to be in equilibrium. In such cases, however, the available data and/or the information in Table 3 may not always be sufficiently detailed to determine unequivocally whether the Transport Regulations apply, in which case a conservative estimate may have to be made by assigning the highest individual radionuclide activity concentration in each decay chain or chain segment to all radionuclides in that decay chain or chain segment. Further information on how to proceed when insufficient data are available on

ED_005285_00000684-00035

individual radionuclide activity concentrations is given in the Transport Regulations.

3.2. EXPOSURE TO GAMMA RADIATION

The main radionuclides contributing to gamma exposure are ^{214}Pb and ^{214}Bi from the ^{238}U decay series and ^{228}Ac, ^{212}Pb and ^{208}Tl from the ^{232}Th decay series. The highest gamma energy (2614 keV) is associated with ^{208}Tl. In the phosphate industry, exposure to gamma radiation from radionuclides in the ^{238}U decay series is the main concern for radiation protection and, as in many other NORM industries, arises mainly from accumulations of mineral concentrates or residues. Dose rates are generally highest near process tanks, piping, filters and large material stockpiles. For workers, workplace monitoring or individual monitoring techniques, or a combination of both, are used.

3.3. EXPOSURE TO RADIONUCLIDES IN INHALED DUST PARTICLES

Airborne dust particles arise from the resuspension of dust that has settled on floors and other surfaces, releases from processing operations and the conveying of minerals. For inhalation of such particles by workers in the phosphate industry, exposure to various radionuclides in the ^{238}U decay series (see Appendix I) and to ^{227}Ac in the ^{235}U decay series is the main concern for radiation protection. In situations where the radionuclide activity concentrations in the materials being handled are moderate, it is important to recognize that the silica content of the airborne dust is likely to be of greater concern for occupational health than the radionuclide content.

3.3.1. Particle size

In the absence of particle size information specific to the workplace concerned, an activity median aerodynamic diameter (AMAD) of 5 μm is normally recommended for airborne dust in the workplace [35] and this could be an appropriate value to use in any initial assessment (see Section 3.1.2.1). However, when subsequently performing a more detailed assessment (see Section 3.1.2.3), measurements may indicate that in some workplaces a higher AMAD (e.g. 10 μm) may be more appropriate.

Where high temperature processes are involved, some radionuclides, notably ^{210}Pb and ^{210}Po, can become volatilized in the furnace fume. In the absence of particle size information, an AMAD of 1 μm is normally

ED_005285_00000684-00036

recommended in situations where this fume contaminates the air in the workplace (in the area around the furnace, for instance). In high temperature processes in the phosphate industry, however, a higher AMAD may be appropriate and the best approach is to determine the particle size distribution for the particular workplace concerned.

3.3.2. Monitoring techniques for workers

In the phosphate industry, as with other NORM industries, routine determination of intakes of radionuclides by workers is, in most cases, achieved using techniques based on air sampling. This approach is consistent with the findings of an investigation into monitoring strategies and methods for optimization of internal exposures of workers exposed to NORM carried out for the European Commission [36]. One of the conclusions of that investigation was that "Air sampling, rather than biological sampling (or whole body counting) is the best way of assessing doses and providing ALARA information".

Guidance on the use of techniques based on air sampling for the monitoring of workers is given in Ref. [4]. Such techniques involve the drawing of air through a filter to capture the dust particles, which are then analysed by measuring the activities of alpha emitting radionuclides in the uranium and thorium decay series. The use of these gross alpha activity measurements to determine the intake is subject to the following considerations:

(a) In materials that have not been chemically processed, the equilibrium of the uranium and thorium decay chains is unlikely to be significantly disturbed, allowing equilibrium to be generally assumed for freshly generated airborne dust particles. However, as discussed in the Annex to Ref. [4], some radon and thoron may have escaped from the dust particles when they are analysed in the laboratory after a delay of some days. The resulting depletion in radon and thoron leads to a corresponding depletion in short lived radon or thoron progeny. For minerals likely to be encountered in the phosphate industry, the retention of radon and thoron can be expected to be in the range 50–100% and it would seem reasonable to assume 75% retention as being typical. On this basis, 1 Bq of ^{238}U captured on the filter corresponds to 7.54 Bq of measured gross alpha activity, while 1 Bq of ^{232}Th corresponds to 5.25 Bq of measured gross alpha activity.

(b) In materials that have been subject to chemical processing, equilibrium conditions in the airborne dust particles can no longer be assumed and the analysis may have to include the measurement of certain individual decay progeny.

ED_005285_00000684-00037

Two basic types of air sampling technique are in use: stationary air sampling (also known as workplace or static air sampling), in which the sampling device remains at a fixed location in the workplace, and personal air sampling, in which the sampling device is attached to the worker in a position such that the air sample is reasonably representative of the air breathed by the worker. The use of stationary air sampling is generally less preferred for dose assessment purposes because the air that is sampled may not be representative of the air breathed by the worker. It is noted in Ref. [36] that the use of stationary air sampling can result in dust inhalation doses being significantly underestimated, sometimes by several orders of magnitude, particularly in workplaces where the resuspension of dust by worker activities is a significant factor. On the other hand, stationary air sampling may result in a significant overestimation of the dose if the worker is not continuously stationed in a dusty area. Three different airborne dust sampling conventions have been established, reflecting different size fractions of the airborne dust particles:

(i) The inhalable fraction (involving AMADs of up to about 100 μm) includes all airborne particles entering the body through the nose and/or mouth during breathing;
(ii) The thoracic fraction (involving AMADs of up to about 30 μm) is the sub-fraction of the inhalable fraction that can penetrate into the tracheo-alveolar region of the lung;
(iii) The respirable fraction (involving AMADs of up to about 10 μm) is the sub-fraction of the inhalable fraction that penetrates into the alveolar region of the lung, including the respiratory bronchioles, the alveolar ducts and sacs.

The selection of the most suitable air sampling device should be based on which dust fraction is to be sampled. A device incorporating an IOM[10] cassette for sampling the inhalable fraction is shown in Fig. 3. The cassette has a 50% sampling efficiency at an AMAD of 40 μm. A sampling device for the thoracic fraction is shown in Fig. 4.

Owing to difficulties in applying personal air sampling to every exposed worker all of the time, monitoring strategies usually involve the assignment of workers to work categories that reflect the general nature and scope of the work activities. In many workplace situations involving exposure to dust containing radionuclides of natural origin, such exposure is not uniform within a work category since a worker may spend time in different exposure environments during the course of the work shift. A further complication arises in accounting for the wearing of respiratory protective equipment.

ED_005285_00000684-00039

Air sampling equipment and techniques have been reviewed in terms of their applicability to radiation protection in workplaces involving exposure to radionuclides in airborne dust [36]. Some of the findings of that review are summarized in the following:

(a) Since air samplers are designed to follow a specific particle size sampling convention based on industrial hygiene sampling criteria, they typically underestimate the true ambient aerosol and thus the activity inhaled. The degree of underestimation depends on the AMAD and geometric standard deviation (GSD) of the particle size distribution of the ambient aerosol and on the type of sampler used. A correction factor can be applied to minimize the degree of underestimation of the airborne activity concentration but this does not remove all of the uncertainty because the AMAD and GSD vary with location, time and circumstances of dust production and can, therefore, never be known precisely.

(b) The aerosol particle size distribution also has a significant effect on the dose coefficient (the committed effective dose per unit intake of activity), leading to an additional source of uncertainty when assessing the effective dose due to the inhalation of particles. The dependence of the dose coefficient on AMAD is particularly strong for particles of lung absorption class S. When assessing the effective dose, it is important to select a sampler with an efficiency that follows as closely as possible the AMAD dependency of the relevant dose coefficients.

(c) Knowledge of the lung absorption class is important because it is needed for determining not only the most appropriate dose coefficient but also the type of sampler that best minimizes the errors arising from an incomplete knowledge of the particle size distribution.

(d) The preferred type of sampling for minimizing dose assessment errors is inhalable sampling for particles in lung absorption class F and thoracic sampling for particles in lung absorption classes M and S. While particles of class M or S are likely to be encountered in many NORM industries, it is pointed out that thoracic samplers are presently not as widely available as inhalable samplers and often are not suitable for alpha counting owing to the dust particles being collected on foam rather than flat filters.

(e) Where the particle size distribution is not known, the assignment of an AMAD of 5 μm has been found reasonable in minimizing errors in assessing the effective dose, whatever the true value of AMAD, sampling

ED_005285_00000684-00040

type, radionuclide and lung absorption class.[11] The assignment of a GSD of 2.5 is recommended by the International Commission on Radiological Protection (ICRP) for aerosols with an AMAD greater than 1 μm when the actual value is unknown [37]. For a GSD of 2.5, sampling efficiency correction factors, as referred to in (a), are given in Table 4.

The activity inhaled by workers, as determined from the alpha counting of dust samples collected on filters, may be underestimated if there is significant alpha particle self-absorption in large particles or in multilayers or agglomerates of smaller particles deposited on the filter. In such cases, dust loadings on filters may need to be restricted accordingly [38]. Various types of filter medium and sampling cassette are available. Where the dust concentration is relatively low (say, about 1–2 mg/m^3) and sampling is undertaken over a 4–6 h period, the choice of filter medium and cassette is not likely to be critical. However, when the dust concentration is relatively high (more than about 3 mg/m^3) and the sampling is undertaken over a period of 8 h or more, the selection of equipment requires more careful consideration. For some types of filter medium, such as PVC, part of the sample may be lost as a result of dust not fully adhering to the surface of the filter. For some types of monitoring cassette, the dust may adhere to the inside wall, requiring it to be removed by washing and added to the material collected on the filter prior to radiometric analysis.

3.3.3. Calculation of effective dose

Dose coefficients (values of committed effective dose per unit intake of activity) for inhalation of radionuclides by workers and members of the public are

TABLE 4. SAMPLING EFFICIENCY CORRECTION FACTORS FOR ESTIMATING THE AIRBORNE ACTIVITY CONCENTRATION OF PARTICLES WITH A GSD OF 2.5 [36]

AMAD (μm)	Correction factor		
	Inhalable sampler	Thoracic sampler	Respirable sampler
1	1.04	1.05	1.11
5	1.18	1.41	2.5
10	1.31	2.1	5.6

[11] The measurement of the AMAD requires specialized equipment such as a cascade impactor.

ED_005285_00000684-00041

specified in a database compiled by the ICRP [39]. The values are based on the model for the respiratory tract described in Ref. [37]. The dose coefficients for workers quoted in Ref. [39] cover a wide range of AMADs. Most of the values for AMADs of 1 and 5 μm appear also in Table III-2A in Schedule III of the BSS [2]. The dose coefficients for members of the public are specified in Ref. [39] for a default AMAD of 1 μm and also in Table III-2E in Schedule III of the BSS [2].

It is pointed out in Ref. [36] that in most NORM industries, the radioactive components of the material involved, and thus of its aerosol particles, are contained within a matrix of non-radioactive elements and their compounds. These matrices often determine the solubility of the particles and it is, therefore, appropriate in such cases to choose the same lung absorption class for all the radionuclides contained within them. It is further pointed out that many of these materials are resistant to all but the most vigorous forms of chemical attack and that their dust particles are obviously lung absorption class S. This reportedly applies to radium rich process scales of the type likely to be encountered in the phosphate industry. However, lung absorption class S may not be appropriate for materials that have been subjected to vigorous chemical treatment. In such cases, it may be more appropriate to determine the lung absorption class experimentally for the particular material involved.

In high temperature processes, the volatile radionuclides ^{210}Pb and ^{210}Po are likely to be removed from the original mineral matrix. When assessing doses arising from the inhalation of furnace fume and precipitator dust, therefore, the most appropriate lung absorption class needs to be determined experimentally.

Inhalation dose coefficients applicable to workers in industrial operations involving low solubility airborne dust particles are given in Table 5. The coefficients relate to lung absorption class S to the extent possible and cover all radionuclides with significant dose contributions. In the few instances where a value for class S is not available, the value given is that corresponding to the next fastest lung absorption class for which information is available.[12] Most of the values in Table 5 are taken from Ref. [39]. In some cases (denoted by bold figures), values for lung absorption class S are not available from this source and data are quoted instead from the results of other calculations [36, 40] based similarly on the ICRP respiratory tract model described in Ref. [37]. Table 6 sets out the inhalation dose coefficients applicable to workers in industrial operations involving medium solubility airborne dust particles such as those that might occur in chemical processing facilities. The coefficients relate to lung absorption class M and are taken from Ref. [39] or, for those figures in bold, from Ref. [36].

[12] The use of dose coefficients for lung absorption classes other than class S in these few instances may lead to some underestimation of the dose.

[a] The dose coefficients quoted are those corresponding to lung absorption class S, except where specified in parentheses as M or F. Values shown in bold are taken from Ref. [36] (rounded to two significant figures) or, in the case of ^{224}Ra, from Ref. [40]. All other values are taken from Ref. [39].

[b] The natural abundance of U-235 is 0.711%, resulting in an activity concentration in natural uranium of 0.046 relative to that of U-238. Consequently, the relative contributions to the inhalation dose from the U-235 decay series radionuclides are insignificant except for that from Ac-227. The dose coefficient for Ac-227 is multiplied by 0.046 in calculating the dose coefficient for the full series.

[c] The values refer to the dose per unit activity of the parent radionuclide.

Many assessments of worker doses reported for NORM industries are based on the inhalation dose coefficients given in Table III-2A in Schedule III of the BSS [2] for AMADs of 1 or 5 μm, since these coefficients, by international consensus, provide the basis for regulation in accordance with the Standards. However, the BSS do not provide coefficients for ^{228}Ra, ^{224}Ra, ^{226}Ra, ^{210}Pb and ^{210}Po in lung absorption class S, with the result that, for low solubility particles, the coefficients for class M (or F in the case of ^{210}Pb) have to be used instead. For medium solubility particles, the coefficients for lung absorption class F have to be

[b] The natural abundance of U-235 is 0.711%, resulting in an activity concentration in natural uranium of 0.046 relative to that of U-238. Consequently, the relative contributions to the inhalation dose from the U-235 decay series radionuclides are insignificant except for that from Ac-227. The dose coefficient for Ac-227 is multiplied by 0.046 in calculating the dose coefficient for the full series.

[c] The values refer to the dose per unit activity of the parent radionuclide.

used for ^{210}Pb. In addition, the dose coefficients for ^{228}Th given in the BSS are different from those incorporated into the ICRP database [39] and given in Tables 5 and 6. For airborne dust particles likely to be encountered in the phosphate industry, the implications of using the BSS coefficients instead of those in Tables 5 and 6 can be estimated from the expected radionuclide solubilities and concentrations in the various process materials. It is found that the implications are significant only for radionuclides of low solubility and depend mainly on the relative concentrations of ^{226}Ra and its progeny. In summary:

ED_005285_00000684-00044

(a) For particles of phosphate ore, phosphate rock or phosphogypsum, all radionuclides can be assumed to be of low solubility. For phosphate ore and phosphate rock, in which near equilibrium conditions prevail, the use of BSS dose coefficients could lead to an underestimation of the inhalation dose by up to 20%. For phosphogypsum, in which there is a high degree of disequilibrium with a characteristically high ^{226}Ra content, the use of BSS coefficients could lead to a more serious underestimation of up to 40%.

(b) For particles of fertilizer product, the decay chains are not in equilibrium and the radionuclide solubility could be regarded as either low or medium, depending on the radionuclide (see Section 6.3.2). Since the concentrations of ^{226}Ra and its progeny are characteristically low, the use of BSS dose coefficients will give doses very similar to those calculated using the coefficients in Tables 5 and 6.

The derivation of the dose coefficients for ^{226}Ra specified in the ICRP database [39], the BSS [2] and Tables 5 and 6 is based on the assumption that ^{222}Rn produced in the respiratory tract does not have the same biokinetic behaviour as its parent ^{226}Ra, but rather is removed to the environment at a rate of 100 d^{-1} (see Annex B of Ref. [41]). Should the removal rate be lower than 100 d^{-1}, the use of these dose coefficients would, by implication, result in the dose being underestimated. In an extreme (and highly unlikely) situation of zero radon removal from the respiratory tract, calculations based on data reported in Ref. [36] suggest that the degree of underestimation could be about 50% for particles of phosphate ore, phosphate rock and phosphogypsum and about 10% for particles of fertilizer.

3.4. SELECTIVE MIGRATION OF RADIONUCLIDES

The mining and beneficiation of phosphate ore involves only physical processes and is, therefore, unlikely to affect the equilibrium that generally exists in the ore. However, chemical or thermal processing of phosphate rock will mobilize the ^{238}U and ^{232}Th decay series radionuclides contained in the ore. This causes different radionuclides to migrate in different ways, thus destroying the equilibrium condition. A knowledge of the resulting radionuclide compositions of the various process materials and products is essential for determining the nature of any control measures that might be needed to ensure that the workers and members of the public are adequately protected.

As an illustration of radionuclide migration during the processing of phosphate ore into fertilizer, a mass balance and a radionuclide balance for a wet process facility processing sedimentary rock are shown in Fig. 5. The activity

ED_005285_00000684-00045

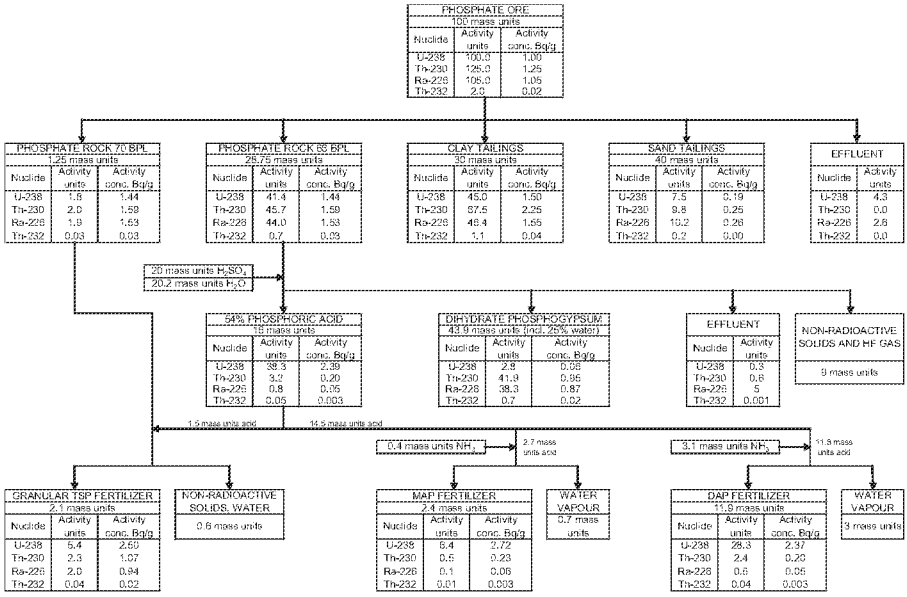

FIG. 5. Typical mass balance and radioactivity balance in the production of phosphate fertilizers in central Florida, USA.

concentrations used in this example are typical of those measured in fertilizer production facilities in central Florida, USA, using local phosphate ore as a feedstock. The relative amounts of the three types of fertilizer shown in Fig. 5 reflect current production patterns. For the production of MAP and DAP fertilizers, phosphate rock with a P_2O_5 content of 30% (66 BPL) is assumed in Fig. 5. This reflects typical historical production values. The exhaustion of high grade rock together with improvements in beneficiation and chemical processing technology has enabled the exploitation of ores with values as low as 24% (52 BPL). During the digestion of the rock with sulphuric acid, the uranium contained within it migrates primarily to the phosphoric acid, whereas most of the radium ends up in the phosphogypsum. The radionuclide composition of the phosphoric acid is, in turn, carried through to the various fertilizer products that are derived directly from it.

ED_005285_00000684-00046

4. MINING AND BENEFICIATION OF PHOSPHATE ORE

4.1. PROCESS DESCRIPTION

4.1.1. Mining

Most commercially exploited sedimentary phosphate deposits are located within a few tens of metres of the earth's surface. These deposits are usually mined by opencast techniques, although some underground mining has been carried out in Egypt, Morocco and the Russian Federation. The overburden and phosphate ore are usually removed by large excavating machines such as electrically operated draglines (see Fig. 6), bucket wheel excavators or electric shovels. In smaller operations, wheeled loaders or hydraulic excavators may be used. Sedimentary phosphate ore currently mined in the USA contains sand, clay, fine particles of phosphate and, in the Florida operations, larger phosphate 'pebbles'. A sample of sedimentary ore from central Florida is shown in Fig. 7. In the mining of igneous deposits and some sedimentary deposits, the overburden and/or phosphate ore has to be broken up by drilling and blasting before it can be removed. The overburden may be set aside for future use in the mine remediation

FIG. 6. Dragline (courtesy: Florida Industrial and Phosphate Research Institute).

ED_005285_00000684-00047

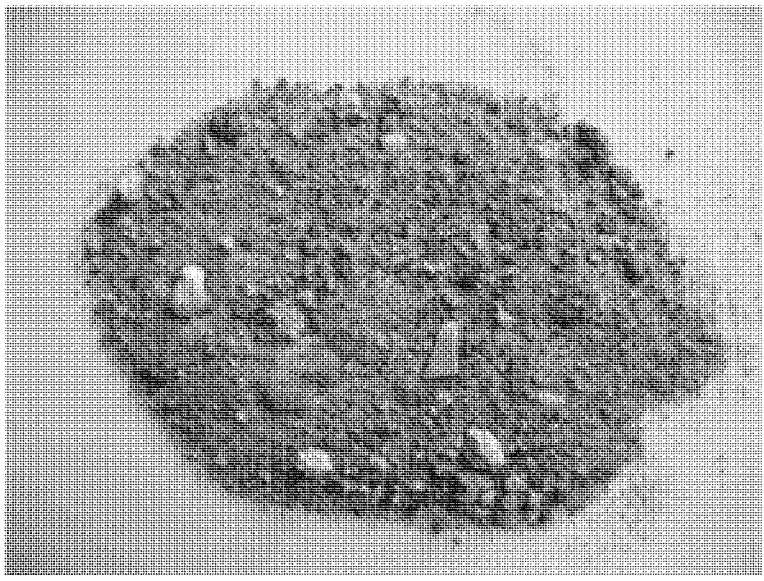

FIG. 7. Phosphate ore of sedimentary origin.

process or returned directly to the mined-out pit area. In some operations the mined ore is exposed to high pressure water jets, as shown in Fig. 8. This generates a slurry, which is pumped directly to the beneficiation plant through a pipeline, as shown in Fig. 9. In other mining operations, the ore may first have to be loaded into trucks for haulage to a nearby crushing facility, after which the crushed ore is transported to the beneficiation plant by a slurry pipeline, train or conveyor. In some hard rock operations, such as those handling ore of igneous origin, the rock is first crushed and then transported by a conveyor to a wet or dry milling facility, after which the milled ore is transported to the beneficiation plant by a slurry pipeline.

4.1.2. Beneficiation

A typical beneficiation process for sedimentary rock is shown schematically in Fig. 10. The first step is usually a wet screening operation ('washing') designed to clean and separate the larger phosphate particles from the slurry and to disintegrate mechanically the large balls of clay. The equipment used may include vibrating and stationary screens as well as log washers, hydrocyclones and clay disintegrators. In operations in Florida, USA, phosphate pebbles (see Fig. 11) are screened out from the clay, sand and sand sized phosphate rock, moved to dewatering tanks and stockpiled by conveyors for

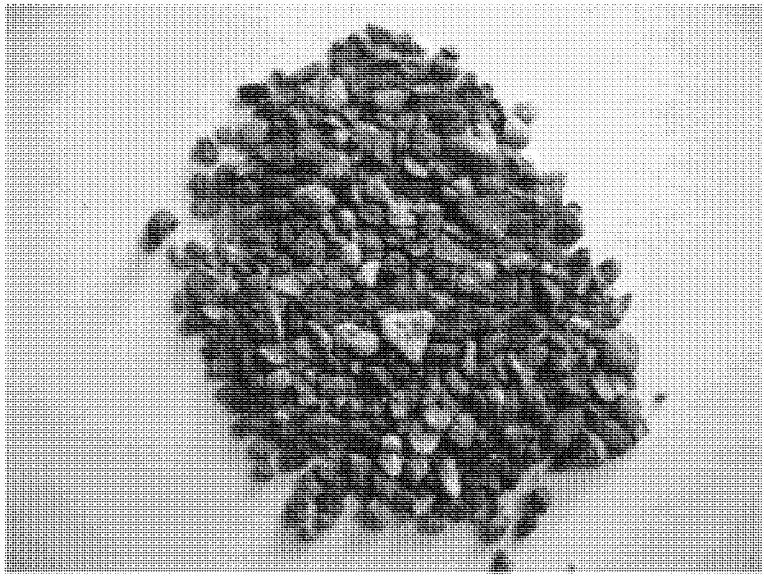

FIG. 11. Phosphate rock (pebble).

ED_005285_00000684-00050

further processing. The clay particles removed from the slurry during the washing process are usually pumped through pipelines to clay storage ponds where the clay slowly settles to the bottom. Clear water is drawn from the top of the pond and pumped back to the beneficiation plant for reuse.

Depending on the characteristics of the ore and the desired quality of the phosphate rock product, ore that has been wet screened may occasionally require no further processing other than dewatering (either naturally or using a centrifuge) and kiln drying. Usually, however, the ore needs to be further upgraded. It is sent to a flotation plant (see Fig. 12) in which various reagents such as fuel oil, soap and fatty acids are used to separate the phosphate particles from residual sand particles. These reagents coat the phosphate particles, allowing increased bonding with the air bubbles released from the bottom of the flotation chamber. The phosphate particles attached to the bubbles are transported to the top of the chamber where they are skimmed off mechanically, as shown in Fig. 13, and scrubbed with dilute sulphuric acid to remove the organic reagents. The material is then frothed with amines to float the remaining quartz. The phosphate rich fraction is pumped to large dewatering vessels, dried and stored in preparation for despatch as 'phosphate rock', the final product of the beneficiation process (see Fig. 14). The sand is pumped back into the mining void

(see Fig. 15) or stockpiled for future use, for example in land remediation. An aerial view of a typical beneficiation plant, illustrating the general plant layout, is shown in Fig. 16 and a closer view of the layout of the beneficiation process is shown in Fig. 17.

Depending on the mineralogy of the ore body, additional process steps may be included in the beneficiation process to remove specific impurities. For instance:

(a) Some phosphate ores contain significant amounts of calcium carbonate (in the form of dolomite or calcite) and/or carbonaceous gangue and organic material. For such ores, a calcining step may be included in the beneficiation process.[13] This involves heating the material to 800–950°C to decompose the impurities and facilitate their removal. The calcining process also improves the reactivity of the rock. Calcining is known to be used in India and Morocco and has been proposed for use in future operations in Saudi Arabia.

FIG. 15. Sand tailings pumped back to the mine cut (courtesy: Florida Industrial and Phosphate Research Institute).

[13] Calcining is a process in which a material is heated to a high temperature without fusing, so that hydrates, carbonates or other compounds are decomposed and the volatile material expelled.

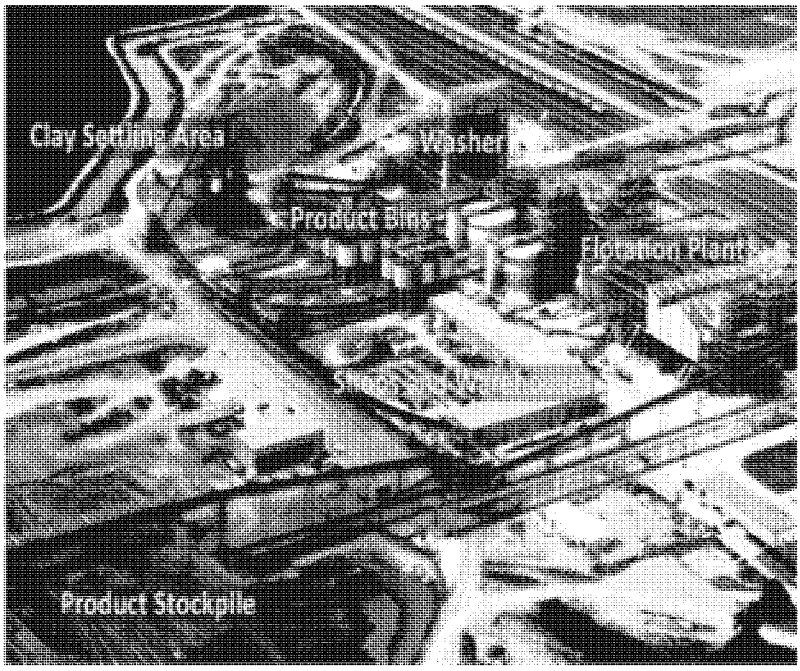

FIG. 16. Overall beneficiation plant layout.

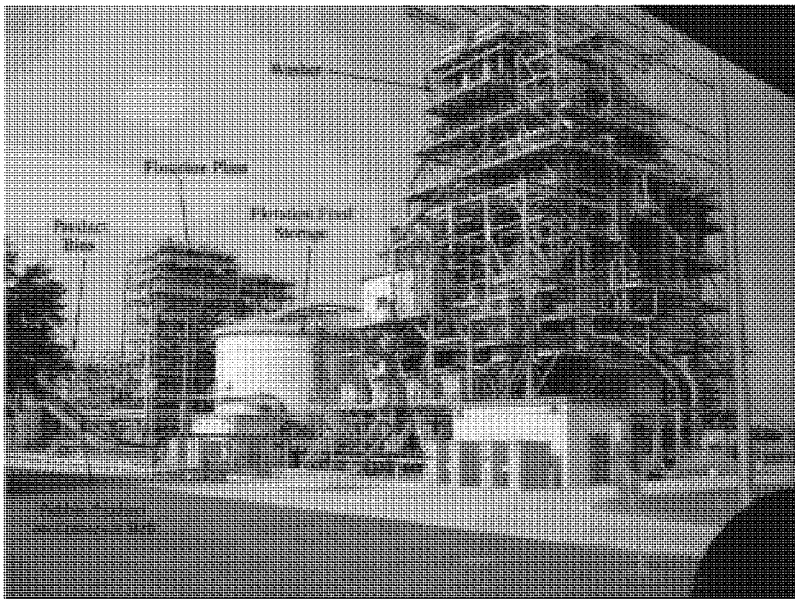

FIG. 17. Layout of the beneficiation process.

ED_005285_00000684-00054

(b) Some igneous ores contain significant amounts of iron, much of which may be removed by magnetic separation techniques. Such techniques are known to be used in Brazil, Canada, Egypt and South Africa.

Specific impurities removed from the ore are sometimes recovered as by-products. In South African igneous phosphate operations, for instance, copper sulphide concentrate and magnetite are recovered for smelting and for use in coal washing, respectively. In some Brazilian operations, baryte and/or magnetite are recovered as by-products.

Data on the chemical composition of phosphate rock are given in Appendix IV. The beneficiation process, by its very nature, gives the phosphate rock a more consistent composition than that of the original ore and, of course, a higher P_2O_5 content. The composition can be summarized as follows:

For phosphate rock of sedimentary origin, the P_2O_5 content is 23–37%. The other major component is CaO, with a concentration of 44–52%. The content of P_2O_5 and CaO combined (tricalcium phosphate) is 80–85%.

Phosphate rock of igneous origin contains higher concentrations of both P_2O_5 (35–42%) and CaO (51–54%). The content of P_2O_5 and CaO combined (tricalcium phosphate) is about 90%.

The fluorine content of phosphate rock (2–4%) is not appreciably different from that found in the ore.

The cadmium content of phosphate rock of sedimentary origin is highly variable within the range 0–100 ppm, whereas the cadmium content of phosphate rock of igneous origin is consistently low (0.25–2 ppm).

Maintenance of the beneficiation plant typically involves the removal of scale and the generation of surface contaminated scrap metal. As there are no chemical changes to the material during the beneficiation process, the selective precipitation of specific elements, including radioactive species, has not been found. Any scales observed consist of hardened phosphate rock or tailings material.

4.1.3. Bulk transport of phosphate rock

In highly industrialized phosphate producing countries such as the USA, it is common for the phosphate rock produced by the beneficiation process to be fed to a chemical processing plant located nearby, often on the same site. The transfer of the phosphate rock to the chemical process plant (or, in some cases, first to a milling facility) is accomplished either in dry form using rail cars, trucks or covered conveyors or as a slurry in a pipeline. When covered conveyors are used, workers using earth moving equipment push the rock from stockpiles into open chutes where the rock falls onto the conveyor.

ED_005285_00000684-00055

In the less industrialized phosphate producing countries, it has been common practice for the phosphate rock to be exported without any further processing. This has necessitated the bulk transport of phosphate rock, often over very large distances, by sea, inland waterway, rail and/or road. However, this situation is changing as a result of increasing transport costs and the tendency for some major rock producing countries to focus more on 'value added' activities such as chemical processing and subsequent conversion into granulated fertilizer (see Section 2.5). As a result, the bulk shipment of rock is beginning to decline in favour of the shipment of fertilizer products.

4.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

4.2.1. Phosphate ore

Cationic radionuclide substitutions in the apatite structure of phosphate ore may include U^{4+}, U^{6+}, Th^{4+}, Ra^{2+}, Pb^{4+}, Pb^{2+}, Po^{4+} and Bi^{3+}. Substitutions may also occur in other minerals incorporated in phosphate ore or may be adsorbed on the surfaces of such minerals. The proportion of uranium substitutions involving the U^{4+} ion is reported to be 40–91% (mean 65%), with the balance involving the U^{6+} ion [42]. It is assumed that U^{4+} substitutes for Ca^{2+} in the apatite structure because these two ions have almost identical ionic radii. However, this type of substitution is limited because the number of Ca^{2+} ions is more than 25 000 times higher than the number of U^{4+} ions available for substitution and there are other, more plentiful, substitute ions available such as sodium and magnesium. Calcium ions may also be substituted with radium, lead, thorium and polonium ions. Uranium concentrations in phosphate ore are given in Table 7.

Data on radionuclide activity concentrations in phosphate ores are given in Appendix II. The following general conclusions can be drawn from these data:

(a) In currently exploited sedimentary phosphate ores, the concentrations of individual ^{238}U series radionuclides generally range from about 0.5 to 3 Bq/g whereas the concentrations of ^{232}Th series radionuclides are generally not significantly elevated above values found in normal rocks and soils.

(b) In currently exploited igneous phosphate ores, the concentrations of both the ^{238}U and the ^{232}Th series radionuclides are elevated (to about 0.1–0.2 Bq/g and 0.1–0.4 Bq/g, respectively). When compared with sedimentary phosphate deposits, the ^{238}U series radionuclide concentrations are lower but the ^{232}Th series radionuclide concentrations are higher.

(c) In ores of both sedimentary and igneous origin, the ^{238}U and ^{232}Th decay chains are generally in radioactive equilibrium.

ED_005285_00000684-00056

TABLE 7. URANIUM IN PHOSPHATE ORE (BY COUNTRY)

Country	Concentration of uranium as U_3O_8 (%)	Reference
Algeria	0.011–0.014	[12]
Brazil	0.008	[12]
India:		[30]
Mussorie	0.04	
Karnataka	0.03–0.08	
Israel	0.005–0.015	[12]
Jordan	0.012–0.015	[12]
	0.024	[43]
Morocco	0.009–0.014	[12]
	0.023	[44]
Tunisia	0.005–0.01	[12]
USA:		
Florida	0.015–0.018	[45]
North Carolina	0.008	[12]

Overall, the activity concentrations in currently exploited phosphate ores are about 0.1–3 Bq/g for radionuclides in the ^{238}U decay series and 0.1–0.4 Bq/g for radionuclides in the ^{232}Th decay series.

4.2.2. Phosphate rock

Data on the radionuclide activity concentrations in phosphate rock product are given in Appendix IV. In summary:

(a) The ^{238}U concentrations in phosphate rock originating from sedimentary deposits generally fall within the range 0.2–2.5 Bq/g.

ED_005285_00000684-00057

(b) The ^{238}U concentrations are significantly lower in phosphate rock originating from igneous deposits (0.03–0.18 Bq/g).
(c) The ^{232}Th concentrations in products of sedimentary origin, as well as in igneous product from Kola, Russian Federation, generally fall within the range 0.01–0.1 Bq/g.
(d) The ^{232}Th concentrations in the igneous product from South Africa (0.3–0.4 Bq/g) are significantly higher than the levels found in most sedimentary products.
(e) The situation regarding other radionuclides in the ^{238}U and ^{232}Th decay series is similar to that for the original phosphate ore. In most cases, the ^{238}U and ^{232}Th decay chains appear to be in approximate radioactive equilibrium [46, 47].

4.2.3. Tailings

A summary of available information on radionuclide activity concentrations in tailings is given in Table 8. The concentrations are generally similar to those in the ore from which they are derived, although for central Florida operations, this is true only for clay tailings — the radionuclide concentrations in sand tailings are typically an order of magnitude lower.

4.3. OCCUPATIONAL EXPOSURE

4.3.1. Exposure pathways

External exposure to gamma radiation occurs through proximity to bulk quantities of process materials, but the degree of such exposure is limited by several factors. Workers in the mining areas operate heavy equipment such as draglines and pit cars and this equipment provides a significant amount of shielding of the operators from gamma radiation. Workers in beneficiation plants spend only limited periods close to bulk material and are shielded by containers and liquids.

Internal exposure occurs through the inhalation of radionuclides in airborne dust while working in the operational areas of the mine and beneficiation plant. The excavation, conveying, crushing, grinding and other handling of dry phosphate rock can generate significant amounts of airborne dust. In the case of wet mining and beneficiation processes, however, dust inhalation is not a significant exposure pathway, even with the highest activity concentrations in known ore bodies, because dust is suppressed by the water used to break up and transport the ore. Exposure to airborne dust may also occur while handling waste

ED_005285_00000684-00058

TABLE 8. RADIOACTIVITY IN TAILINGS FROM THE BENEFICIATION OF PHOSPHATE ROCK

Source	Activity concentration (Bq/g)[a]				
	U-238	Th-230	Ra-226	Th-232	Th-228
Tailings from sedimentary ore[b]

USA, central Florida (sand) [16, 47]	0.055–0.4	0.25	0.06–0.45	0.004	—
USA, northern Florida [47]	0.01–0.03	—	0.07–0.1	—	—
Tailings from igneous ore					
South Africa [48]	0.26 (0.22–0.30)	—	0.25 (0.19–0.28)	0.33 (0.26–0.44)	0.34 (0.22–0.46)

[a] Some values have been rounded.

[b] Higher values than those listed in the table have been encountered, but these are not representative of current commercial operations. In tailings from former sedimentary phosphate mining in the United Republic of Tanzania, the activity concentrations were 4.3 Bq/g for ^{226}Ra and 0.6 Bq/g for ^{228}Ra and ^{228}Th [49].

materials and surface contaminated objects and while cleaning or refurbishing contaminated equipment.

In opencast mining operations, no significant buildup of radon daughters occurs. Similarly, beneficiation plants are open to outside air exchange and there is again little opportunity for the buildup of radon progeny above ambient levels. If mining is conducted underground, opportunities exist for the significant buildup of radon progeny in the workplace atmosphere, with the extent of any such buildup depending strongly on the ventilation conditions.

4.3.2. Exposure levels

4.3.2.1. Gamma dose rates

For the relatively low concentrations of ^{238}U and ^{232}Th decay series radionuclides in phosphate ore and phosphate rock, the dose rate depends primarily on the activity concentration of the material rather than its total quantity and geometry. Using a theoretical modelling technique described in Ref. [50], gamma dose rates per unit activity concentration have been calculated at a

ED_005285_00000684-00059

distance of 1 m from a 1000 m^3 volume of material in which radionuclides in each of the ^{238}U and ^{232}Th decay series were assumed to be in equilibrium. The predicted dose rate associated with uranium series radionuclides is 0.39 μSv/h per unit activity concentration of ^{238}U (in becquerels per gram). For thorium series radionuclides, the corresponding figure is 0.58 μSv/h per unit activity concentration of ^{232}Th. The predicted dose rate from ^{40}K is 0.04 μSv/h per Bq/g. These dose factors have been applied to phosphate ore and phosphate rock using radionuclide activity concentrations selected from Appendix II and Appendix IV, respectively.[14] The results are given in Table 9. In Ref. [51] a mean dose rate of 0.54 μSv/h was calculated for 14 worldwide rock sources. Excluding an unrepresentative value for Tanzanian rock, the mean dose rate was 0.39 μSv/h. These values are consistent with those given in Table 9.

Gamma dose rates measured at two mines and beneficiation plants in the Syrian Arab Republic [52] are shown in Table 10. These results are very similar to the theoretical values reported in Table 9.

Extensive area monitoring using thermoluminescent dosimeters (TLDs) in rock tunnels used for transporting rock to a phosphoric acid plant in central Florida, USA, was carried out over a period of four years. The absorbed dose rates were in the range 0.08–3.4 μGy/h and rarely exceeded 1 μGy/h. The average absorbed dose rate was 0.18 μGy/h [53].

Gamma dose rates from phosphate ore can be summarized as follows:

(a) Dose rates associated with sedimentary material are generally a few tenths of a microsievert per hour, rarely exceeding 1 μSv/h, with the ^{238}U series radionuclides contributing almost the entire dose.
(b) Dose rates associated with igneous material are 0.1–0.3 μSv/h, significantly lower than those associated with sedimentary material. Material from Kola, Russian Federation, gives significantly lower dose rates than material from South Africa. About 60–80% of the dose is attributable to the ^{232}Th series radionuclides, with the ^{238}U series radionuclides contributing most of the balance.

[14] In order to demonstrate the relative contribution of all radionuclides, only data sets that included activity concentrations of ^{238}U and ^{232}Th series radionuclides as well as ^{40}K were selected from Appendices II and IV. Some ^{40}K concentrations were determined from the K_2O content given in Appendix IV.

4.3.2.2. Inhalation of airborne dust

Measurements of airborne dust activity concentrations in sedimentary phosphate mining and beneficiation facilities in Florida, USA, are reported in Ref. [53]. Dust samples were collected on filters using either a high volume stationary air sampler or low volume personal air samplers. Alpha counting of the dust samples suggested an airborne ^{238}U activity concentration of 5–10 mBq/m^3 in the mining area. Higher dust levels, up to 100 mBq/m^3, were measured in the crushing, grinding and screening areas of the beneficiation plant. Although some of the dust levels were high, the occupancy periods of workers were reported to be only a small fraction of the total working period. In addition, workers were often required to use respiratory protective equipment as part of normal OHS procedures.

4.3.2.3. Inhalation of radon

Radon exposures were measured at two mining and beneficiation facilities in the Syrian Arab Republic [52], at mining and beneficiation plants in central Florida, USA [53], and in underground mines in Egypt [54, 55]. The results are summarized in Table 11. Assuming an equilibrium factor of 0.4 and an annual working period of 2000 h, the potential alpha energy exposures at Syrian facilities (0.3–1.1 mJ·h·m^{-3}) imply an annual average radon concentration of about 65–245 Bq/m^3. Elevated exposures of administrative workers at the Al-Sharkeia mine were reportedly caused by the offices being built on phosphate sands and being poorly ventilated, especially in winter. Remedial action in these particular workplaces was proposed. At benefication plants in Florida, USA, the radon concentrations in the flotation plant, pit cars and railcar loading area were consistent with indoor radon concentrations. Measurements were also made in mining and rock handling areas. With the exception of rock tunnels, background levels were not exceeded. The high radon and radon progeny concentrations measured in Egyptian underground mines were the result of poor ventilation.

4.3.3. Effective dose

4.3.3.1. Gamma radiation

Annual effective doses received by workers from external gamma radiation have been assessed using data from three countries and are summarized in Table 12. In the Syrian Arab Republic, doses received by workers in two sedimentary phosphate mining and beneficiation facilities have been determined from the dose rate

measurements reported in Table 10 [52]. In South Africa, doses received by workers in an igneous phosphate mining and beneficiation facility have been determined from measurements made with a portable gamma dose rate meter [56, 57]. In central Florida, USA, doses received by workers in sedimentary phosphate facilities have been determined from external exposure measurements using both lithium fluoride thermoluminescence dosimeters (LiF TLDs) and the more sensitive aluminium oxide carbon-doped luminescence dosimeters (Al_2O_3:C OSLDs) [53].

4.3.3.2. Inhalation of airborne dust

Annual effective doses received by workers from the inhalation of airborne dust are reported from facilities in South Africa and the USA and are summarized in Table 12. The doses were assessed from measurements conducted with personal air samplers (South Africa) or high volume stationary air samplers (USA).

ED_005285_00000684-00065

4.3.3.3. Total effective dose

For an igneous phosphate mining and beneficiation facility in South Africa, summing of the doses from external gamma exposure and inhalation of airborne dust gives total annual effective doses in the range 0.1–1 mSv (Table 12). The mean total annual effective dose received by workers in sedimentary phosphate mining and beneficiation facilities in Florida, USA, was calculated from measured exposure levels and found to be in the range 0.12–0.30 mSv [53]. In the mining area at this plant, 75% of the total dose arises from external exposure whereas in ore crushing, grinding and screening locations the reverse is the case, with the majority of the dose arising from internal exposure.

4.3.4. Transport of material

External gamma dose rates and annual doses received by workers involved in the transport of phosphate rock are reported in Refs [58, 59]. Doses received from external exposure to gamma radiation were calculated from exposure measurements and estimated maximum exposure periods. The results are shown in Table 13. With respect to sea transport, gamma dose rates arising from the loading of sedimentary phosphate rock originating from Morocco and Florida, USA, were found to be elevated above background levels, whereas the corresponding dose rates for igneous rock from Kola, Russian Federation (not shown), were not elevated. Dose rates for inland transport by ship were measured on a barge loaded with phosphate rock originating from Morocco and having activity concentrations at the upper end of the normal range. As expected, the highest doses were those arising from loading operations, owing to the closer proximity of the workers involved. Exposures during rail transport occur only while loading and unloading. Exposures for truck transport occur during loading and unloading and during transport as measured in the truck cab. The annual doses received by workers were all significantly less than 1 mSv.

4.4. PUBLIC EXPOSURE

Members of the public in the vicinity of phosphate rock mining and beneficiation operations may be exposed through the following pathways:

(a) Inhalation of dust and radon dispersed from the operations;
(b) Ingestion of groundwater contaminated with radionuclides migrating from the mining and tailings management facilities;

ED_005285_00000684-00066

TABLE 13. EXPOSURE OF WORKERS INVOLVED IN THE TRANSPORT OF PHOSPHATE ROCK [58]

Exposure situation	Dose rate (μSv/h)	Annual dose (mSv)
Sea transport, loading	0.10	0.09
Inland ship:		
Loading	0.26	
Transport	0.10	
Overall		0.18
Railway, loading and unloading	0.26	0.29
Truck:		
Loading and unloading	0.26	
Transport	0.16	
Overall		0.33

(c) Ingestion of foodstuffs affected by water and soil contamination through leaching and dust fallout;
(d) External gamma radiation from contaminated soil and bulk residues.

Exposure of members of the public, irrespective of the pathway involved, is likely to be very low because mining and beneficiation operations tend to be conducted at considerable distances from residential areas and involve materials with low activity concentrations. Most rock handling and processing operations are conducted under wet conditions. Under unfavourable wind conditions, it is possible for members of the public to be exposed to radionuclides in airborne dust generated by the crushing, milling and drying of rock. The migration of radionuclides from mining and residue management facilities into water bodies could result in the contamination of drinking water and food but, again, this exposure pathway is not expected to be significant, particularly because process water is usually recycled within the facility.

A study was conducted to determine if there was an elevated health risk due to ingestion of radionuclides (^{226}Ra and ^{210}Pb) or toxic metals (cadmium, lead and mercury) in fish harvested from lakes on previously mined lands in the central Florida phosphate region [60]. The study examined ten lakes in total:

(a) Four unreclaimed lakes (pit lakes that are formed when strip mining cuts fill with water and the site is abandoned for nature to recover with no attempt to reclaim the land);

ED_005285_00000684-00067

TABLE 14. ESTIMATED INCREMENTAL DOSE RECEIVED BY A MEMBER OF THE PUBLIC LIVING NEXT TO AN IGNEOUS PHOSPHATE MINING AND BENEFICIATION FACILITY [61]

Source of dose	Annual committed effective dose (rounded) (μSv)
Gamma radiation from soil	0.004
Inhalation:	
Airborne dust	16
Radon	1
Ingestion:	
Leafy vegetables	0.1
Root vegetables	0.3
Fruit	0.1
Meat	3
Milk	0.6
Cereals	0.1
Poultry	0.2
Eggs	0.07
Total	21

(b) Two reclaimed lakes (lakes created as part of the mining process that are contoured, vegetated and stocked with fish to resemble and function like natural lakes);
(c) Three natural lakes (lakes in the study area that were formed by natural means and regarded as 'control' lakes unaffected by mining);
(d) One reservoir (an artificially constructed lake that was unrelated to phosphate mining).

Six species of fish were sampled, representing those most commonly consumed by humans. The radionuclide data indicated no significant health risk attributable to the former mining activities. Radium is known to concentrate in bones, but the bones of fish are not normally consumed in the study region and so the risk from bones was largely discounted. There was no difference in lead or cadmium levels among the different types of lake. However, it was noted that mercury levels in fish from natural lakes were higher than in those from the mining-impacted lakes and may be due to the fact that natural lakes tend to be

ED_005285_00000684-00068

much older and have greater surface to volume ratios (more shallow areas), which provide more time and surface area to capture global fallout of mercury.

Another study in Florida, USA, surveyed radioactivity in food produced from a variety of land types, including mined lands (concentrating on lands which were reclaimed after phosphate mining) and unmined lands underlain with phosphate deposits [62]. More than 100 food samples were collected from 62 land parcels and analysed. This was followed by a study that investigated, more broadly, the presence of radioactivity in locally grown or caught foods, concentrating mainly on foods grown on reclaimed clay lands [63]. In extensive studies of foods grown on mined lands [62, 63], the doses were found to be trivial (less than 10 μSv/a).

Approximately 70 individual food samples were collected from five land parcels in the central Florida phosphate district and analysed for ^{226}Ra, ^{210}Pb and ^{210}Po. Corresponding soil samples were collected and analysed both for these radionuclides and for a variety of soil chemistry parameters. The results of the radioactivity and soil chemistry analyses of these samples were integrated into the database, which had been created from the initial study, and a variety of statistical analyses were conducted on this integrated data set [63]. The results of these analyses indicated that the concentrations of ^{226}Ra and ^{210}Pb in edible crops grown on mined phosphate lands were statistically higher than those in crops grown on unmined phosphate lands. However, the ^{210}Po concentrations were extremely low, with many being below the lower limit of detection, and the dose from food consumption was only a small fraction of that received by an average individual from other environmental sources of radioactivity. An individual who sourced all the sampled food types from the reclaimed clay land areas and all remaining food types from the general food pool was estimated to receive a committed effective dose of 191 μSv in a year from food consumption. By comparison, the corresponding ingestion dose received by an individual obtaining all food from the general food pool was estimated to be 164 μSv. Thus, the incremental ingestion dose attributable to the former mining operation was only 27 μSv per year. Two beef samples were analysed, one from mined land and one from unmined land. Each sample was replicated three times, yielding a total of six beef observations. The geometric mean values of ^{226}Ra activity concentration were 0.000147 and 0.000126 Bq/g for mined and unmined land, respectively. The difference between these results is statistically insignificant.

A dose assessment was conducted at an igneous phosphate mining and beneficiation facility in South Africa [61]. The assessment considered a member of the public residing on the perimeter of the facility, with all drinking water being obtained from an external source that was not influenced by the operation of the facility. The doses attributable to the operation of the facility were estimated from measurements of the concentrations of radionuclides in various

ED_005285_00000684-00069

environmental media, including surface water, groundwater and food, using conservative assumptions. The results are given in Table 14.

4.5. REGULATORY CONSIDERATIONS

In terms of the Standards, it is unnecessary to regulate (as a practice) material in which the activity concentrations of radionuclides in the uranium and thorium decay chains do not exceed 1 Bq/g. This criterion is of particular relevance to the mining and beneficiation of phosphate ore because the radionuclide activity concentrations in the materials involved are all rather moderate and may well be less than 1 Bq/g. Moreover, the nature of the processes involved is such that radionuclides do not become concentrated in scale and other deposits inside pipes and vessels, so the application of the 1 Bq/g criterion would generally require only a knowledge of the activity concentrations in the ore, phosphate rock and tailings.

4.5.1. Mining and beneficiation of phosphate ore of igneous origin

All radionuclide activity concentrations in the phosphate ore, phosphate rock and tailings are less than 1 Bq/g, implying that it is not necessary to regulate the mining and beneficiation of ore of igneous origin. This conclusion is supported by dose assessments which show that the annual effective doses received by workers and by members of the public do not exceed 1 mSv by any significant amount. The adoption of good OHS and environmental protection practices (not specifically aimed at radiological concerns) are likely to bring about further reductions in the already low levels of radiation exposure.

4.5.2. Mining and beneficiation of phosphate ore of sedimentary origin

While the activity concentrations of radionuclides in the ^{232}Th decay series in the phosphate ore, phosphate rock and tailings are all less than 1 Bq/g, the same is not always true of the radionuclides in the ^{238}U decay series. For those operations in which the activity concentrations of radionuclides in the ^{238}U decay series exceed 1 Bq/g, the doses received by workers and by members of the public need to be taken into account when considering the possible need for regulation as a practice. All indications are that in such situations, the doses arising from external gamma exposure and inhalation of airborne dust are unlikely to exceed 1 mSv. In those few instances where the ore is mined by underground methods, the radon concentrations to which the underground workers are exposed would have to be considered.

ED_005285_00000684-00070

It can be concluded that most mining and beneficiation operations involving material of sedimentary origin are candidates for exemption by the regulatory body, particularly if the operation is known to be conducted in accordance with good OHS and environmental protection practices. For some operations, a requirement for notification and even authorization in the form of a registration might be appropriate if there are concerns about airborne dust and contamination of water bodies. It may be necessary for the regulatory body to ensure that measures are in place to:

(a) Minimize airborne dust both inside and outside the plant;
(b) Control the way in which process water is managed; and/or
(c) Monitor the quality of nearby groundwater and surface water bodies.

In the case of underground mining, remedial action to reduce radon concentrations through improved ventilation might also be needed.

4.5.3. Transport of bulk material

The radionuclide activity concentrations of phosphate ore, phosphate rock and tailings are well below the levels at which the Transport Regulations would become applicable (see Section 3.1.3). Consequently, such material can be transported without any restrictions or controls of a radiological nature. This conclusion is supported by the results of dose assessments carried out for various transport scenarios.

5. PRODUCTION OF PHOSPHORIC ACID BY THE WET PROCESS

5.1. PROCESS DESCRIPTION

Digestion of phosphate rock with sulphuric acid is by far the most common type of wet process used for phosphoric acid production. Digestion with hydrochloric acid is used to a lesser extent for producing high purity phosphoric acid for use in foodstuff applications.

ED_005285_00000684-00071

5.1.1. Sulphuric acid digestion

5.1.1.1. Main process

A mixture of sulphuric acid and recycled phosphoric acid is added continuously to phosphate rock in a reactor vessel or 'attack tank'. The rock is digested by the sulphuric acid to produce phosphoric acid and calcium sulphate, known as phosphogypsum. Each tonne of P_2O_5 produced in the form of phosphoric acid is matched by 4–6 t of phosphogypsum (dry weight). The basic chemical reaction can be represented by:

$$Ca_3(PO_4)_2 + 3H_2SO_4 \rightarrow 3CaSO_4 + 2H_3PO_4$$

As the rock particles react, they tend to become coated with an insoluble layer of calcium sulphate, hindering further reaction. The presence of the recirculated phosphoric acid, as well as control over the rock particle size, minimizes this problem. The sequential chemical reactions are as follows:

$$Ca_3(PO_4)_2 + 4H_3PO_4 \leftrightarrows 3Ca(H_2PO_4)_2$$

and

$$3Ca(H_2PO_4)_2 + 3H_2SO_4 \leftrightarrows 3CaSO_4 + 6H_3PO_4$$

The chemical reaction for the digestion of fluorapatite may be expressed as follows:

$$Ca_{10}(PO_4)_6\,F_2 + 10H_2SO_4 + 20H_2O \leftrightarrows 10CaSO_4{\cdot}2H_2O + 6H_3PO_4 + 2HF$$

Following acid attack, the resulting phosphoric acid is transferred to one or more filtration assemblies, commonly of the tilting pan type (see Fig. 18), in order to separate the acid from the phosphogypsum.[15] The phosphogypsum is in a hydrated form, the degree of hydration depending on the process conditions, in particular the temperature, the P_2O_5 concentration and the free sulphate content. The main forms of phosphogypsum produced are the dihydrate form ($CaSO_4{\cdot}2H_2O$) and the hemihydrate form ($CaSO_4{\cdot}\frac{1}{2}H_2O$). After separation from

[15] Less commonly, either rotary table or travelling belt filtration is used.

ED_005285_00000684-00072

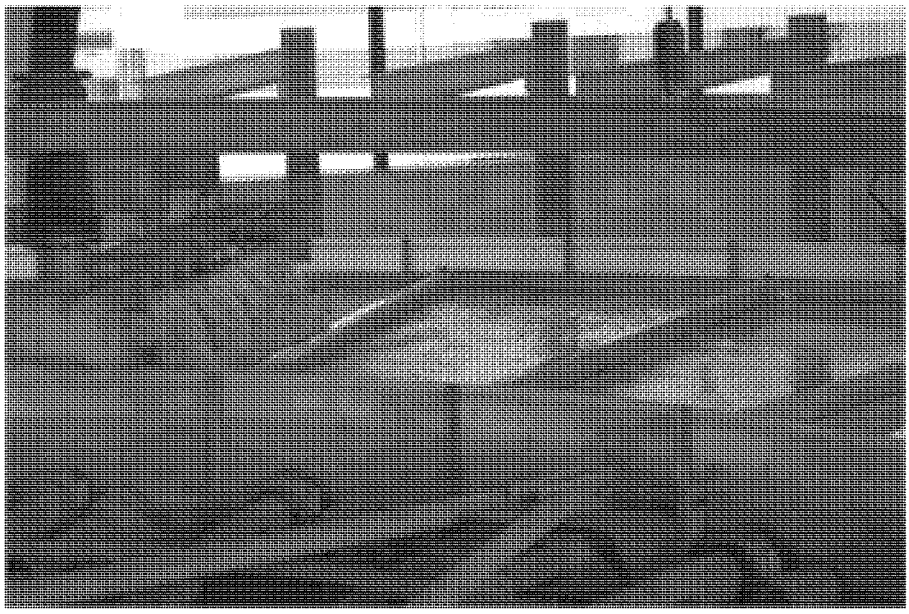

FIG. 18. Tilting pan filtration equipment.

the phosphoric acid, the wet phosphogypsum is sent to a residue pile (stack) for storage, usually after washing to remove traces of phosphoric acid and fluoride. The default condition for the subsequent use of phosphogypsum is the dihydrate form, since the hemihydrate and other hydrate forms convert rapidly to the dihydrate form. The rehydration process may begin even before separation from the phosphoric acid and the conditions for rehydration become more favourable still during washing and upon exposure to environmental moisture during transport and storage.

Several variants of the sulphuric acid digestion process are in commercial use [64] and are summarized in Appendix V. Each method has its advantages and disadvantages, with the choice of method in a particular situation depending on a variety of considerations, such as the complexity and cost of the processes and process equipment involved, the nature and level of experience of plant personnel, limitations on the quality and particle size of the feedstock material, the efficiency of P_2O_5 recovery and the quality of the phosphoric acid and phosphogypsum produced [65]. Most of the early phosphoric acid plants used one of the simpler methods based on dihydrate phosphogypsum production. The desire for improvements in energy efficiency, P_2O_5 recovery and phosphoric acid purity has led to a growth in popularity of methods based on hemihydrate

ED_005285_00000684-00073

phosphogypsum production, although these improvements have come at the cost of greater challenges for plant operators.

The compositions of the process materials are not easy to characterize in terms of origin or country since each manufacturing facility has its own strategy for obtaining phosphate rock feedstock, often depending on availability and economic factors. Heavy metals (such as arsenic, cadmium, chromium, lead and mercury) and fluoride originating from the ore become distributed between the phosphoric acid and phosphogypsum products, the exact distribution being very much dependent on the type of phosphate ore, the process and the type of impurity.

The phosphoric acid reactor is drained and cleaned periodically, typically annually. The thickness of the scale that accumulates on the walls of the reactor ranges from several centimetres to a metre or more. Scale may also accumulate on the roof of the tank, particularly near the point where the sulphuric acid is added. The scale consists predominantly of phosphogypsum and non-radioactive compounds such as sodium fluosilicate (Na_2SiF_6) and sodium potassium fluosilicate ($NaKSiF_6$). Removal of the scale is accomplished by high pressure water jetting and mechanical equipment.

The acid leaving the reactor contains residual minerals that are dissolved at saturation or supersaturation levels. These minerals are subsequently precipitated, leading to the accumulation of sediment and the deposition of radium rich scale on the relatively cool internal surfaces of pipes, vessels and filtration equipment. If allowed to build up, this sediment and scale can seriously reduce the flow capacity of pipes and interfere with the functioning of the filtration equipment. To help prevent this, the lines in a phosphoric acid plant are flushed every 1–2 weeks to purge the solids that have settled out and remove some of the scale adhering to the pipe walls. In addition, the filtration pans are periodically cleaned by dry chipping and abrasion and the filtration cloths that cover the tilting pans are replaced (see Fig. 19). Since flushing does not remove all the scale, some pipes affected by scaling are eventually replaced.

The buildup of residues such as scale in pipes and filtration equipment can be minimized by refinements to the production process [66]. As an example, in plants using the hemihydrate method (see Appendix V), scale formation can be eliminated by the incorporation of a simple hemihydrate rehydration step or by the addition of a small quantity of anti-scaling agent to the single stage filtration system.

ED_005285_00000684-00074

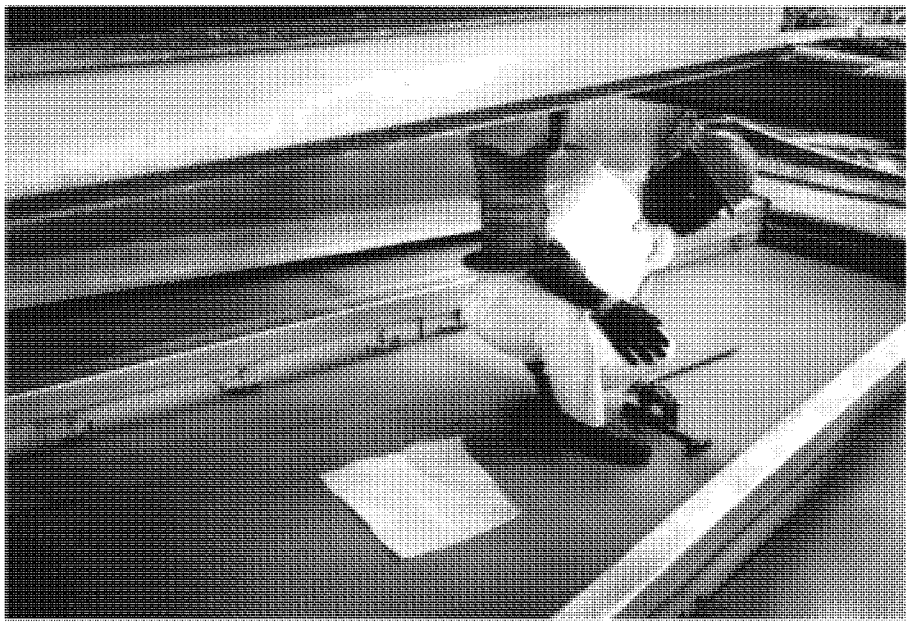

FIG. 19. Maintenance worker replacing the filter cloth on a tilting pan filtration assembly (courtesy: Florida Industrial and Phosphate Research Institute).

5.1.1.2. Further processing of phosphoric acid

Phosphoric acid emerging from the filtration step in any of the 'weak acid' methods (see Appendix V) has a P_2O_5 content in the range 24–36% and a typical residual solids content of some 2%. For most industrial applications, additional concentration and/or purification steps are required. First, the strength of the phosphoric acid is increased by evaporation to 40–55% P_2O_5. The design of the evaporation equipment takes account of the corrosive nature of the phosphoric acid and the very high scaling characteristics of the vapour released during the concentration process. The heat exchangers are fabricated from graphite or stainless steel, while the remaining equipment is made from rubber lined steel. An example of the acid composition at this stage, prior to further purification, is given in Table 15.

In many plants, a flocculant is then added to the acid and the solids are settled in a clarifier. At about 40% P_2O_5, the solubilities of residual fluosilicates and phosphogypsum are both at a minimum. As a result, many plants use this property to clarify the acid at the 40% level. The clarifier underflow contains, in

ED_005285_00000684-00075

TABLE 15. EXAMPLE OF PHOSPHORIC ACID COMPOSITION PRIOR TO PURIFICATION [48]

Main chemical constituents (%)		Trace elements (ppm)	
P_2O_5	55	Cl	175
MgO	2	As	14
Al_2O_3	0.05	Cd	2
Fe_2O_3	0.45	Cu	200
K_2O	0.04	Pb	1
Na_2O	0.05	V	20
SO_4^{2-}	3.18	Mn	250
F^-	0.28	Sr	2
		Cr	30

addition to fluosilicates and phosphogypsum, minor amounts of magnesium, aluminium and fluorine compounds and is sent back to the attack tank or to a separate filter for recovery of the remaining phosphate. Scale builds up on the walls of the 40% clarifiers and surge tanks. Since the buildup is slow, it does not require periodic removal. When the tanks eventually need to be relined, the scale is fully removed using a combination of high pressure water jetting and mechanical equipment.

Other purification methods such as solvent extraction, crystallization and ion exchange may also be used to remove impurities from the phosphoric acid. In the solvent extraction purification process, the H_3PO_4 is extracted by passing the crude acid through one or more organic phase extraction columns using a solvent such as a short chain (4–8 carbon atoms) alcohol, ketone, ether or amine. This technique removes 60–75% of the P_2O_5 contained as an impurity in the crude acid and converts it to H_3PO_4. The purified acid is then recovered in the backwash step using countercurrent extraction and concentrated to achieve the required P_2O_5 content.

Further concentration of phosphoric acid beyond 40–55% P_2O_5 causes various phosphates to precipitate. A typical formulation is $(Fe)_3NaH_{14}(PO_4)_8$, where aluminium can substitute for iron and ammonia and potassium can substitute for sodium, depending on availability [67]. These solids, which contain more than 50% P_2O_5, may be left suspended in the acid or may be removed by settling in a clarifier or by centrifuging, the choice being dictated by the final product specifications.

ED_005285_00000684-00076

The P_2O_5 content of phosphoric acid may be further increased by partially converting it from the orthophosphoric form (H_3PO_4) to polyphosphate forms, resulting in a product known as superphosphoric acid. The process involves a condensation reaction in which two or three orthophosphoric acid molecules are converted into higher polymeric forms. The basic chemical reactions are:

$$2H_3PO_4 \rightarrow H_4P_2O_7 + H_2O$$

and

$$3H_3PO_4 \rightarrow H_6P_3O_{10} + 2H_2O$$

The P_2O_5 content of superphosphoric acid is very high, exceeding even that of 100% orthophosphoric acid. Such high P_2O_5 concentrations are achieved by evaporating essentially all of the free moisture, including that generated in the condensation of the orthosphosphate, using high pressure evaporation units. The colour of superphosphoric acid is either light green ('green superphosphoric acid') or black ('black superphosphoric acid'), depending on whether the orthophosphoric acid from which it is derived has been manufactured from calcined rock or uncalcined rock, respectively. Most green superphosphoric acid is used for the manufacture of 10-34-0 liquid ammonium polyphosphate fertilizer, a product containing 60% $(NH_4)_3PO_4$ and 40% H_2O. The high polymeric content allows the sequestration of other cationic metals, such as iron, aluminium, magnesium and zinc. The product is often used to carry these micronutrients to the recipient crops. Black superphosphoric acid may either be sold as such for industrial uses or further processed by oxidation to produce green superphosphoric acid.

The production of superphosphoric acid typically begins with acid having a strength of 40–47% P_2O_5 that has been clarified to remove some of the magnesium, aluminium and fluorine compounds that precipitate out at that strength. After concentrating to a strength of 54% P_2O_5, the acid is fed into an alloy evaporator. Further concentration leads to the conversion of about 25–30% of the P_2O_5 content from the orthophosphate form to polyphosphate forms, giving a final product strength of at least 70% P_2O_5. In a variation of this process, several manufacturers in the USA use feed acid that has been subjected to minimal clarification and remove the impurities later in the process by subjecting the superphosphoric acid to pressure filtration. Scale formation occurs during the production of superphosphoric acid [68].

Figure 20 shows the scale inside a pipe in a green superphosphoric acid plant that was found to contain fluorine rich compounds, while Fig. 21 shows the

ED_005285_00000684-00077

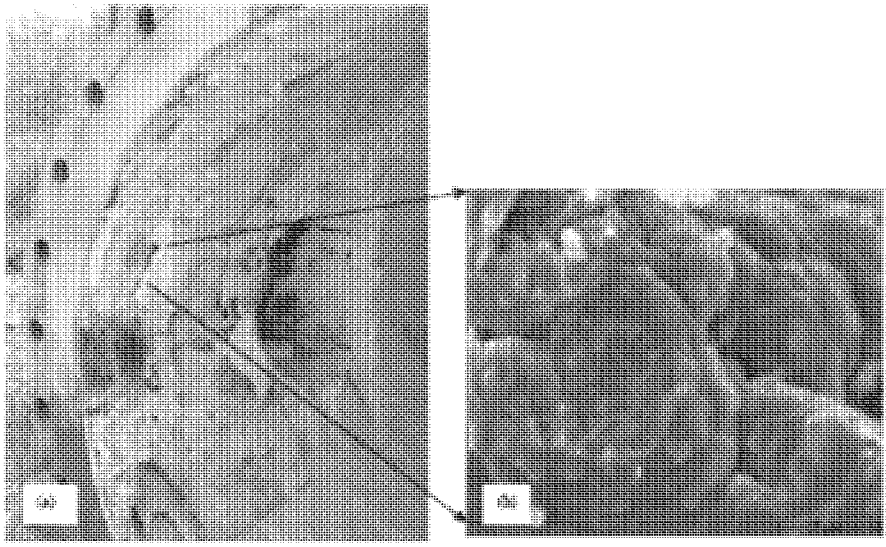

FIG. 20. Pipe scale observed in a green superphosphoric acid plant [68].

scale inside a green superphosphoric acid storage tank consisting primarily of calcium sulphate enriched in radium.

Phosphoric acid produced by the reaction of phosphate rock with sulphuric acid contains fluorine as hydrogen fluoride (HF), fluosilicic acid (H_2SiF_6), fluorosilicate salts (especially salts of Na and K) and metal fluoride complexes involving Al and Fe, making it unsuitable for use in certain applications, such as the production of animal feed supplements. There are several methods for reducing the fluorine content, of which the easiest and cheapest is generally to add reactive silica (diatomaceous earth) to convert the fluorine compounds into SiF_4 while concentrating the acid in a forced circulation evaporator to expel HF and SiF_4. Other methods of reducing the fluorine content include air stripping, steam stripping and concentration to superphosphoric acid followed by dilution back to orthophosphoric acid.

5.1.1.3. Management of residues

The scale removed periodically from the attack tank, which is predominantly non-radioactive, is transported by truck to the phosphogypsum stack.

Radium-bearing scale is removed from pipes, vessels and filtration equipment by abrasion or chipping and is usually sent to the phosphogypsum

ED_005285_00000684-00078

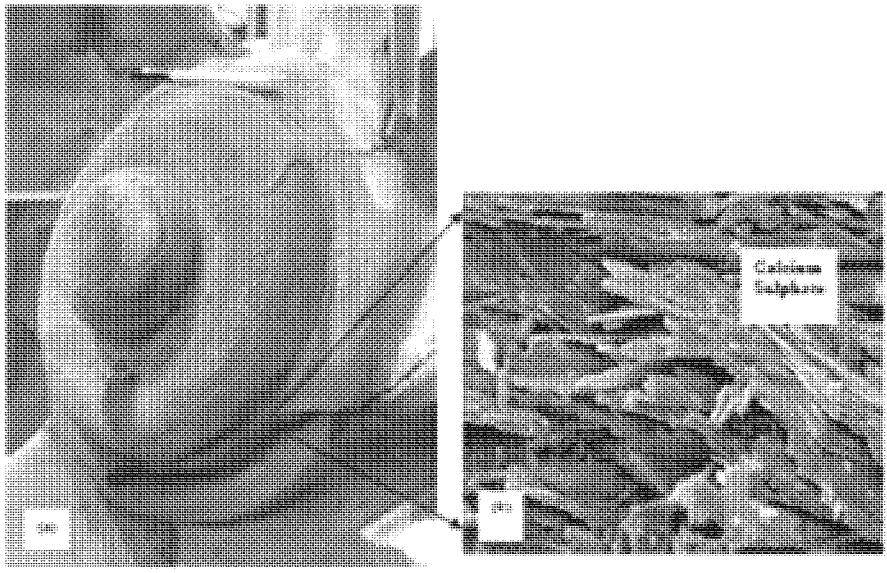

FIG. 21. Scale observed inside a green superphosphoric acid storage tank [68].

stack. The removal of scale in this way can cause localized site contamination that may subsequently need to be remediated. Alternatively, contaminated objects, particularly the filter pans and equipment, may be sent to off-site facilities for cleaning and refurbishing. This may result in the accumulation of radium-bearing scale at off-site premises.

The solid residues that settle out in the phosphoric acid clarification tanks are mixtures of very fine material comprising non-processed phosphate rock and non-filtered phosphogypsum [69]. They also contain fluosilicates and compounds of magnesium, aluminium and fluorine. This finding is supported by the following analytical results [70]:

(a) The concentrations of trace elements and Fe in the residues are similar to those found in the phosphate rock.
(b) The concentrations of Zn, Sr and Y are higher than the average values in normal sediments and soils.
(c) Elevated concentrations of Ca (14.2%, 19.3%), S (8.2%, 10.7%) and P (6.6%, 13.5%) are found in residues from plants in Senegal and Morocco, respectively.

ED_005285_00000684-00079

The residues are mostly recycled back to the attack tank or, in some cases, sent to the phosphogypsum stack.

When 40–55% phosphoric acid is purified using solvent extraction, the raffinate from the extraction process takes the form of a low grade acid containing the remaining P_2O_5. It may be used as a fertilizer provided that its cadmium content, which can be as high as 60–100 ppm, does not exceed local legal limits. Solvents can be recovered from the raffinate and the purified acid and recycled back to the process.

The concentration of acid beyond 55% generates suspended solids containing more than 50% P_2O_5. If these are removed, they are usually recycled back to the attack tank or used to make a low phosphate content fertilizer product such as MAP (see Section 6). Where a clarifier is used, the underflow may be sent to a filter and the phosphate-containing solids from this filter sent to the phosphogypsum stack. The solids that are separated out during the production of green superphosphoric acid also contain high concentrations of P_2O_5. They are used in the manufacture of other end products such as MAP fertilizer.

Rubber linings, where used, tend to become impregnated with radioactive material and are replaced periodically. The contaminated linings are sent to controlled disposal facilities specifically designed and authorized for the disposal of radioactive waste.

Process water used in various stages of the production process, including wastewater generated by the flushing of pipes, vessels and filtration equipment, is recycled by sending it to a large pond on the phosphogypsum stack for cooling and for settling or redissolution of solids before being returned to the process. Accordingly, process water is sometimes referred to as 'pond water'.

5.1.2. Hydrochloric acid digestion

Processes have been developed in Israel and the USA for the production of high purity phosphoric acid by the acidulation of phosphate rock with hydrochloric acid, although only the Israeli process has been practised commercially [71]. These processes have limited application and their environmental impact is reported to be in need of consideration [72].

A detailed description of the Israeli process, shown schematically in Fig. 22, is given in Refs [45, 73]. The dissolution of phosphate rock by hydrochloric acid results in an aqueous solution of primarily calcium chloride and phosphoric acid and the emission of hydrogen fluoride, according to the reaction:

$$[Ca_3(PO_4)_2]_3 \cdot CaF_2 + 20HCl \rightarrow 6H_3PO_4 + 10CaCl_2 + 2HF$$

ED_005285_00000684-00080

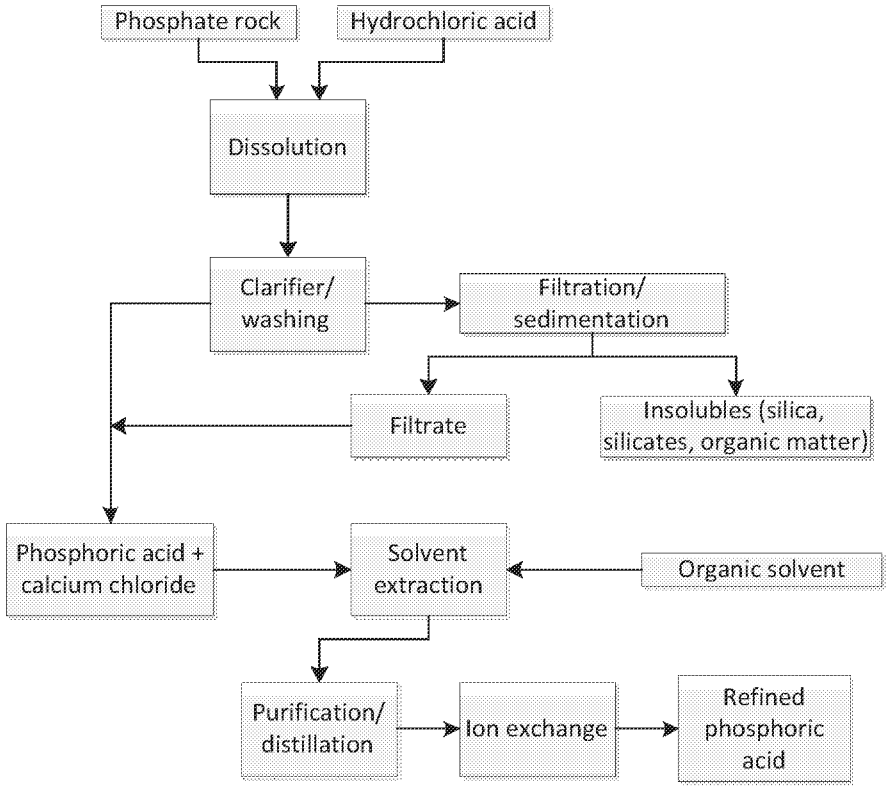

FIG. 22. Hydrochloric acid digestion process for the production of high purity phosphoric acid.

Other acid soluble components of the rock, such as $CaCO_3$, decompose simultaneously. The small amount of insoluble residue remaining comprises primarily silica, silicates and insoluble organic matter. This residue can be separated by filtration or by sedimentation in a thickener, followed by washing. The choice of method depends on economic considerations and on the precise nature of the residue.

Phosphoric acid is then selectively extracted from the dissolution liquor using a countercurrent organic solvent extraction process, leaving a calcium chloride brine containing most of the impurities, such as iron and fluorine. The brine is stripped with steam to recover any dissolved solvent. The brine is either disposed of in the sea or on land, depending upon site specific economic and environmental considerations. The solvent, now loaded with phosphoric acid, also contains trace amounts of Ca^{2+} ions and other impurities and is further purified by multistage countercurrent contact with isoamyl alcohol, normal

ED_005285_00000684-00081

butanol or a mixture of the two. The loaded solvent is then washed with a mixture of hydrochloric and phosphoric acids at controlled concentrations and stripped with water to recover the phosphoric acid. The stripped solvent, which is now almost completely acid free, extracts the remaining acids present in the raffinate and is recycled back to the extraction step. The phosphoric acid product contains some residual hydrochloric acid and dissolved solvent. The solution is concentrated to a P_2O_5 content of 69% in what is essentially a distillation process, during the course of which the residual hydrochloric acid and solvent are separated and recovered. The purity of the phosphoric acid so produced is much higher than that achievable from sulphuric acid digestion (see Section 5.1.1), although still not as high as that achievable from elemental (thermally produced) phosphorus (see Section 13).

5.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

5.2.1. Sulphuric acid digestion

Uranium is present in the phosphate rock primarily as the tetravalent ion U^{4+} and to a lesser extent the hexavalent ion U^{6+}. During the acid digestion process, ferrous iron readily reduces the U^{6+} present in the rock to U^{4+}. The reduction is also catalysed by fluoride ions originating from the rock. During acid filtration, contact with air results in oxidation to the hexavalent form and the uranyl ions complex mainly with phosphates. During the digestion process, 90–95% of the uranium in the phosphate rock migrates to the phosphoric acid [47], where it exists in the form of a uranyl phosphate complex and, to a lesser extent, uranyl sulphate and fluoride complexes. Uranium concentrations in phosphoric acid with a P_2O_5 content of 30% are given in Table 16 [45]. The remaining uranium in the phosphate rock migrates to the phosphogypsum, principally as a constituent of unreacted rock. Since ^{238}U and ^{234}U exist in the same chemical form, they remain in equilibrium during the digestion process.

Most of the radium in the phosphate rock migrates to the phosphogypsum. The exact amount depends on factors such as the process conditions and the characteristics of the phosphate rock. Percentages reported in the literature include 70–85% [47], 83.5% [74], 90% [75] and 92–93% [69]. Data on radioactivity levels in phosphogypsum are given in Section 10.3.

There are conflicting findings on the migration of lead during the digestion process. Some reports indicate that most or all of the lead in the phosphate rock migrates to the phosphogypsum, probably as poorly soluble lead sulphate [46, 76]. Other reports indicate that most or all of the lead migrates to the phosphoric acid [47, 75, 77].

ED_005285_00000684-00082

TABLE 16. URANIUM CONCENTRATIONS IN 30% PHOSPHORIC ACID [45]

Country	Concentration of uranium as U_3O_8 (%)
Algeria	0.013
Brazil	0.008
Israel	0.0165
Jordan	0.0165
Morocco	0.014
Tunisia	0.008
USA:	
Florida	0.019
North Carolina	0.008

Most of the polonium in the phosphate rock migrates to the phosphogypsum. Percentages reported in the literature include 78% [75], 99% [47], 87–94% [69] and more than 99% [78].

As with lead, there are conflicting findings on the migration of thorium during the digestion process. The behaviour of thorium seems to depend strongly on the process conditions and the characteristics of the phosphate rock. Thorium forms sparingly soluble salts with hydroxides, fluoride and phosphate, while sulphate compounds are relatively soluble.[16] Some studies have found that up to 75% of the thorium migrates to the phosphoric acid [79–81]. However, another study indicated that 80% of the thorium migrated to the phosphogypsum [75].

Radionuclide activity concentrations in phosphoric acid are given in Table 17. The ^{238}U activity concentrations vary over a wide range (0.14–2.6 Bq/g). The activity concentrations of ^{238}U can also be determined from the uranium concentrations in Table 16 by assuming that 1 g of U_3O_8 contains 12 347 Bq of ^{238}U. The activity concentrations determined in this way (in this case for 30% phosphoric acid) are similar to those reported in Table 17 but confined to a narrower range (1.0–2.3 Bq/g). The activity concentrations of radionuclides other than ^{238}U are, as expected, generally much lower.

Radionuclide activity concentrations in residues from phosphoric acid production are given in Table 18. In most cases, the activity concentrations are moderate (up to a few becquerels per gram). In some scales, however,

[16] The predominant complexes are expected to be fluoride, phosphate and sulphate.

^{226}Ra activity concentrations as high as 4000 Bq/g have been found. The activity concentration of ^{226}Ra in scale deposited on the internal surfaces of pipes, vessels and filtration equipment can reach as high as 3700 Bq/g [82–84].

5.2.2. Hydrochloric acid digestion

While this process has been well studied, little is known about the fate of the radionuclides introduced via the phosphate rock feedstock. The chemical conditions suggest that all the radionuclides, including uranium and radium, dissolve in the hydrochloric acid with only trace quantities remaining in the residue consisting of small amounts of silica, silicates and insoluble organic matter. The subsequent solvent extraction step is not likely to extract any of the radionuclides, leaving them in the calcium chloride raffinate. Radium, in particular, is chemically similar to calcium. However, even if the raffinate is evaporated to dryness, the radionuclide activity concentrations will be less than those in the phosphate rock feedstock because of the increase in mass. The phosphoric acid product is expected to contain negligible amounts of uranium and other radionuclides after the extraction and purification steps, but may contain some residual thorium.

In this process, hydrochloric acid is recovered from the phosphoric acid in the evaporators. Since radionuclides are dissolved in the hydrochloric acid, evaporators could be possible points of contamination, activity buildup and exposure. The mixing tanks used for recycling of hydrochloric acid could also be subject to contamination and activity buildup over time.

5.3. OCCUPATIONAL EXPOSURE

Most phosphoric acid production plants use the sulphuric acid digestion method and the information on occupational exposure given in this section is mostly related to this method.

5.3.1. Exposure pathways

The potential for significant occupational exposure occurs mainly in work activities associated with the handling of phosphate rock feedstock and the operation and maintenance of filtration equipment used for acid–phosphogypsum separation [89]. External exposure to gamma radiation is one of the main exposure pathways and is likely to be of concern in the following areas and activities:

ED_005285_00000684-00086

(a) Feedstock rock handling;
(b) Attack tank mixing compartments and agitators;
(c) Filtration equipment, in particular, scale laden pipes, distributors for rotating tilting pan filters and operating filter pans;
(d) Acid clarification and storage, in particular, clarification and storage tanks containing settled sludge;
(e) Equipment maintenance, in particular, exposure to radium rich scale during activities such as the replacement of pipes, the cleaning of evaporator heat exchangers, the repair of filter cloths and the mechanical removal of filter pan scale by chipping and abrasion.

The other main exposure pathway is via inhalation of radionuclides in airborne dust. This is likely to be of concern in the following areas and activities:

(a) Feedstock rock handling;
(b) Attack tank maintenance;
(c) Filtration equipment during repeated filtration and washing;
(d) Equipment maintenance, in particular, activities involving dry material such as filter pan scale chipping.

Exposure via the inhalation of radon is only likely to be of concern in highly enclosed and poorly ventilated areas in which process material is stored or handled. The tunnels within which phosphate rock is conveyed from storage areas to the processing plant ('rock tunnels') could represent such a situation if not adequately ventilated (see Table 11). In all other working areas, there is little potential for significant accumulations of radon to occur.

In the case of plants using the hydrochloric acid digestion method, exposures of workers are expected to occur mainly in the solid residue and scale handling areas.

5.3.2. Exposure levels

5.3.2.1. Gamma dose rates

Gamma dose rates during routine plant operation have been measured in workplaces at several phosphoric acid production plants and the reported values are summarized in Table 19. In most cases, the incremental gamma dose rates in phosphoric production plants in normally occupied areas are less than 0.2 μSv/h but may attain 2 μSv/h close to concentrated acid tanks or filtration systems.

Gamma dose rates can be higher during maintenance operations. The highest dose rates are likely to be those associated with the buildup of radium rich scale

ED_005285_00000684-00087

TABLE 19. GAMMA DOSE RATES IN PHOSPHORIC ACID PRODUCTION PLANTS

Location	Average incremental dose rate (μSv/h)
Spain (during processing of rock from Morocco and Kola) [46]:

Germany [87]:	
Several phosphoric acid plants	0.1–1.9
Production halls, acid collection tanks (worker occupied areas)	0.2

within equipment [92]. This occurs primarily in the phosphogypsum filtration system. In tilting pan filtration equipment, scale builds up in the pans, filter cloths, central filtrate distribution system and piping and can give rise to absorbed dose rates of up to 75 μGy/h on contact during normal operation [89]. Piping between the attack tank and the phosphogypsum filtration area can also accumulate radium rich scale [53]. Some of this piping can give rise to dose rates of 100 μSv/h, as measured on contact with the pipes in the maintenance workshops. Similarly, the filtration assembly, especially underneath the filters near the distribution hub, can produce dose rates on contact in the range 100–120 μSv/h during maintenance [92].

Gamma exposure data have been reported for maintenance activities in South African phosphoric acid plants processing phosphate rock of either igneous origin or 75% igneous and 25% sedimentary origin [48]. The results are summarized in Table 20. It is evident that the highest dose rates are those associated with maintenance work inside the flash coolers.

5.3.2.2. Airborne dust

Airborne dust measurements were carried out in a phosphoric acid plant in Huelva, Spain [93]. The ^{238}U, ^{230}Th and ^{232}Th airborne activity concentrations

ED_005285_00000684-00088

TABLE 20. EXPOSURE TO GAMMA RADIATION DURING PLANT MAINTENANCE ACTIVITIES [48]

Plant	Annual exposure period (h)	Average dose rate (μSv/h)
Attack tanks:

Circulating vessels:		
Manual scale removal	16	0.5

were 0.3, 0.2 and 0.1 mBq/m^3, respectively, for an average mass concentration of 0.37 mg/m^3. Gross alpha and beta activity concentrations determined in airborne dust in phosphoric acid production plants in Florida, USA, are reported in Ref. [53]. The alpha activity concentrations were 40–70 mBq/m^3. Airborne dust inhalation does not appear to be a significant exposure pathway in wet process phosphoric acid production facilities.

5.3.2.3. Inhalation of radon

Radon and radon progeny concentrations were measured in plants in Huelva, Spain [94] and in central Florida, USA [53]. Under normal operating conditions, concentrations were found to be similar to background levels. This included the rock tunnels at the plants in Florida, where the potential alpha energy concentration of radon progeny was found to be consistently less than 0.02 μJ/m^3. The radon progeny concentration was also measured in rock tunnels under abnormal conditions, that is, after a long period with the ventilation fans not in operation. Although the potential alpha energy concentration was found to have increased, it still did not exceed 0.2 μJ/m^3. Assuming an equilibrium factor of 0.4, this potential alpha energy concentration is equivalent to a radon gas

ED_005285_00000684-00089

concentration of the order of 100 Bq/m^3. Although this is higher than the worldwide average indoor radon concentration, it is not uncommon for such a level to be found in many homes and the occupancy period of the worker is, in any case, very short in comparison. Consequently, it can be concluded that the inhalation of radon is not a significant exposure pathway.

5.3.3. Effective dose

5.3.3.1. Gamma radiation

Most modern phosphoric acid plants incorporate a high degree of automation, which minimizes exposure periods in areas of high dose rates during normal operation. During maintenance operations inside process vessels, dose rates may be higher but, again, the annual exposure periods are short. Assessments of the annual effective doses from gamma radiation received by workers at various phosphoric acid plants around the world can be summarized as follows:

(a) In central Florida, USA, doses were assessed using individual monitoring of workers by means of LiF TLDs and the more sensitive Al_2O_3:C OSLDs [53]. The radionuclide activity concentrations in the phosphate rock feedstock (of sedimentary origin) were about 1.4 Bq/g for the ^{238}U decay series and less than 0.03 Bq/g for the ^{232}Th decay series.

(b) Doses received by workers at four phosphoric acid plants in Poland were assessed using a pressurized ion chamber and LiF TLDs deployed at fixed locations [91]. The phosphate rock feedstock was of sedimentary origin, imported from northern Africa (Morocco, Tunisia and Algeria), the USA and the Middle East. The activity concentrations of the radionuclides in the ^{238}U decay series were typically about 1.5 Bq/g.

(c) Doses were assessed using a gamma dose rate meter and measured occupancy periods at a plant in Spain. The plant was processing rock of sedimentary origin imported from Morocco and igneous rock imported from Kola, Russian Federation [46].

(d) Doses received during maintenance work inside process vessels were assessed at plants in South Africa, using the average dose rates and annual exposure periods given in Table 20. The origin of the phosphate rock feedstock was either igneous or a mixture of 75% igneous and 25% sedimentary [48].

The results of these assessments, which are summarized in Table 21, suggest that the workers receiving the highest annual doses (up to 0.35 mSv)

ED_005285_00000684-00090

TABLE 21. DOSES RECEIVED BY WORKERS FROM EXPOSURE TO GAMMA RADIATION IN PHOSPHORIC ACID PLANTS

Worker category	Mean annual effective dose (mSv)
Workers handling phosphate rock feedstock:	
Central Florida, USA [53]	0.194–0.300
Four plants in Poland [91]	0.05
Phosphoric acid production workers:	
Central Florida, USA [53]	0.264–0.348
Huelva, Spain [46]	0.135–0.212
Maintenance workers, South Africa [48]:	
General maintenance inside attack tanks	0.035
Manual scale removal inside attack tanks	0.045
General maintenance inside flash coolers	0.024
Manual scale removal inside flash coolers	0.072
General maintenance inside concentrators	0.041
Erection of scaffolding inside concentrators	0.004
Manual scale removal inside circulating vessels	0.008
Service workers working mainly off-site on the repair of pumps, filter pans and other equipment, central Florida, USA [53]	0.066–0.175

work in the attack tank and filtration areas. The doses received by workers engaged in the handling of phosphate rock feedstock are lower, while maintenance workers and service personnel receive the lowest doses.

5.3.3.2. Airborne dust

The dose from inhaled airborne dust was assessed during routine operation in a phosphoric acid production plant in the Islamic Republic of Iran [90] by air sampling and alpha activity measurements. The average internal dose for the plant was 0.14 mSv/a, with a range of 0.04–0.33 mSv/a across different workplaces. The maximum inhalation dose was found in phosphate rock bulk storage areas.

ED_005285_00000684-00091

Results for phosphoric acid plants in Florida, USA, were published as dose distributions [53]. The most probable doses were <0.05 mSv/a for workers handling phosphate rock feedstock and <0.02 mSv/a for workers engaged in the actual phosphoric acid production process.

5.3.3.3. Total effective dose

Summing the dose values given in Sections 5.3.3.1 and 5.3.3.2 gives total annual effective doses of about 0.1–0.3 mSv for workers handling phosphate rock feedstock and 0.3–0.4 mSv for workers involved in the main phosphoric acid production process. For a plant in the Islamic Republic of Iran, the annual effective dose to workers, averaged over all workplaces, was 0.78 mSv.

Little information is available on doses received by workers in plants using hydrochloric acid digestion. The indications are that the doses from gamma exposures and radon inhalation are well below 1 mSv/a [95].

5.3.4. Measures to reduce doses

The undertaking of regular gamma surveys and the education of workers are examples of measures that, at a relatively low cost, have proven to be effective in ensuring that workers do not spend unnecessary time in areas of high gamma dose rates. Where the nature of the work requires workers to spend time close to high activity material such as radium rich scale in filtration equipment, the use of shielding has enabled doses to be reduced. Measures taken to minimize the formation of scale for purposes of maintaining plant performance (see Section 5.1.1.1) have the added advantage of minimizing workers' exposure to gamma radiation.

Various approaches have been used to minimize the doses received by workers via the inhalation of airborne dust. These include improvements in the design of process equipment, the adoption of measures to reduce the spillage of material and the installation of equipment to control airborne dust levels. The growing use of wet grinding of the phosphate rock feedstock instead of the more traditional dry grinding methods is particularly effective in reducing doses arising from dust inhalation, since wet grinding techniques do not generate any airborne dust. There is also no misting from wet grinding as it takes place inside the mill.

5.4. PUBLIC EXPOSURE

There is little potential for members of the public to receive significant exposures from phosphoric acid production facilities. The activity concentrations

ED_005285_00000684-00092

in bulk materials are moderate and exposure to gamma radiation outside the site boundary can be expected to be negligible. Phosphoric acid plants are potential sources of airborne dust containing radionuclides. However, this dust tends to become rapidly deposited in the vicinity of the source and is unlikely to be transported to nearby residential areas. This has been confirmed by airborne dust monitoring around plants in central Florida, USA [96]. There is also little potential for public exposure via contamination of surface water bodies. Process water is generally recycled from the phosphogypsum stacking system back to the acidulation process. Normal environmental protection requirements will generally ensure that any water that is discharged from the facility is treated to reduce contaminant concentrations (including radionuclide concentrations) to acceptable levels.

The phosphogypsum stacks themselves are potential sources of public exposure. More details are provided in Section 10.4.

5.5. REGULATORY CONSIDERATIONS

Radionuclide activity concentrations in many of the process materials may exceed 1 Bq/g, with values sometimes reaching a few becquerels per gram in bulk materials (phosphate rock feedstock, phosphoric acid and phosphogypsum) and, occasionally, a few thousand becquerels per gram in the scale that accumulates inside pipes, vessels and filtration equipment. In terms of the Standards, therefore, wet process phosphoric acid production needs to be considered for regulation as a practice.

Evidence suggests, nevertheless, that doses arising from exposure to these materials are not high enough to be of serious concern. Annual doses received by workers are less than 1 mSv, while members of the public are unlikely to receive any significant dose. Consequently, it is expected that regulatory control would be limited to just a few basic requirements, with authorization in the form of a registration probably being the most appropriate regulatory option. During routine plant operation, the regulatory body would need to be satisfied that good OHS and environmental protection practices (including control of discharges) are being followed, that reasonable efforts are being made to ensure that doses remain below levels of concern and that exposure conditions in the workplace are reviewed as appropriate, for instance, if circumstances change. During non-routine operations, procedures would need to be in place to ensure that the doses received by maintenance workers, especially those engaged in the removal and handling of scale, remain below levels of concern. The scale itself would need to be disposed of at an approved hazardous waste facility.

ED_005285_00000684-00093

With the exception of some of the scales removed from pipes and vessels during maintenance operations, the radionuclide activity concentrations in all the process materials are such that the Transport Regulations would not apply to these materials during transport.

6. MANUFACTURE AND USE OF AMMONIUM PHOSPHATE FERTILIZERS

Ammonium phosphates are a class of predominantly granular fertilizers produced by reacting phosphoric acid with ammonia. These fertilizers have a high nutrient content and convenient handling characteristics. They combine, in a single application, the two essential fertilizer ingredients, nitrogen and phosphate, in proportions favoured by the agricultural market and are referred to generically as NP fertilizers. The addition of potassium during the manufacturing process results in the production of NPK fertilizers. The favourable characteristics of ammonium phosphate fertilizers result in them being by far the most widely traded phosphate fertilizers worldwide [45]. There are two basic types of ammonium phosphate fertilizer:

(i) MAP, typically containing 10–11% N and 50–52% P_2O_5;
(ii) DAP, typically containing 18% N and 46% P_2O_5.

The primary emphasis of commercial production is increasingly on DAP.

6.1. PROCESS DESCRIPTION

6.1.1. Main process

MAP and DAP are produced by the reaction of phosphoric acid with ammonia. As phosphoric acid is tribasic (that is, having three replaceable hydrogen ions), it can form monoammonium, diammonium or triammonium phosphate salts, depending on the number of hydrogen ions replaced by ammonium ions (NH_4^+). Thus, the replacement of only one hydrogen ion produces MAP ($NH_4H_2PO_4$), while the replacement of two hydrogen ions produces DAP ($(NH_4)_2HPO_4$).

ED_005285_00000684-00094

The primary reactions are:

$$H_3PO_4 + NH_3 \rightarrow NH_4H_2PO_4$$

and

$$NH_4H_2PO_4 + NH_3 \rightarrow (NH_4)_2HPO_4$$

Triammonium phosphate is unstable in ambient conditions, rapidly losing ammonia and reverting to the stable diammonium phosphate form. The production process for MAP and DAP fertilizer products consists of a 'pre-neutralization' step, using either a conventional reactor or a 'pipe cross reactor', followed by a granulation step. The ammoniation reaction is exothermic, with the reaction temperature reaching 115–120°C. During the granulation process, a potassium salt may be added, resulting in the production of NPK fertilizer.

In the conventional pre-neutralizer reactor method, ammonia (anhydrous liquid ammonia or, in some cases, ammonia gas or a gas–liquid mixture) is added to phosphoric acid, increasing the ammonia:acid mole ratio and causing the acid to become partially neutralized. Usually, 65–70% of the total phosphoric acid requirement is fed to the pre-neutralizer in the form of clarified acid (52–54% P_2O_5). The use of clarified acid ensures that it is free of any iron or aluminium phosphate impurities, these being undesirable because they cannot be ammoniated. The balance of the acid requirement may be provided in the form of relatively unclarified 28% P_2O_5 acid although, with a decline in quality of some phosphate rock feedstocks, clarified acid may be preferred in some situations. The balance of the acid requirement may also be provided in the form of scrubber liquor extracted from the scrubber system, containing 20–30% P_2O_5. The degree of ammoniation is carefully controlled to produce a slurry with an ammonia:acid mole ratio of 0.5–0.7 for MAP production and 1.3–1.4 for DAP production.[17] The slurry is then introduced to a granulator for further ammoniation and production of granular product (see Fig. 23). The slurry is distributed on a bed of recycled undersized ammonium phosphate product while the remaining ammonia required for completion of the reaction is introduced from below the bed. Granulation occurs by agglomeration and coating of the recycled MAP or DAP particles with the appropriate slurry. This final stage of the ammoniation reaction is controlled to a mole ratio of 1.0 for MAP production and 1.90–1.95 for DAP production.

[17] In some facilities, MAP is produced by a 'back titration' method, in which a 1.3–1.4 mole ratio (DAP) slurry is first generated and then more acid is added to lower the ratio to the required 0.5–0.7 range.

ED_005285_00000684-00095

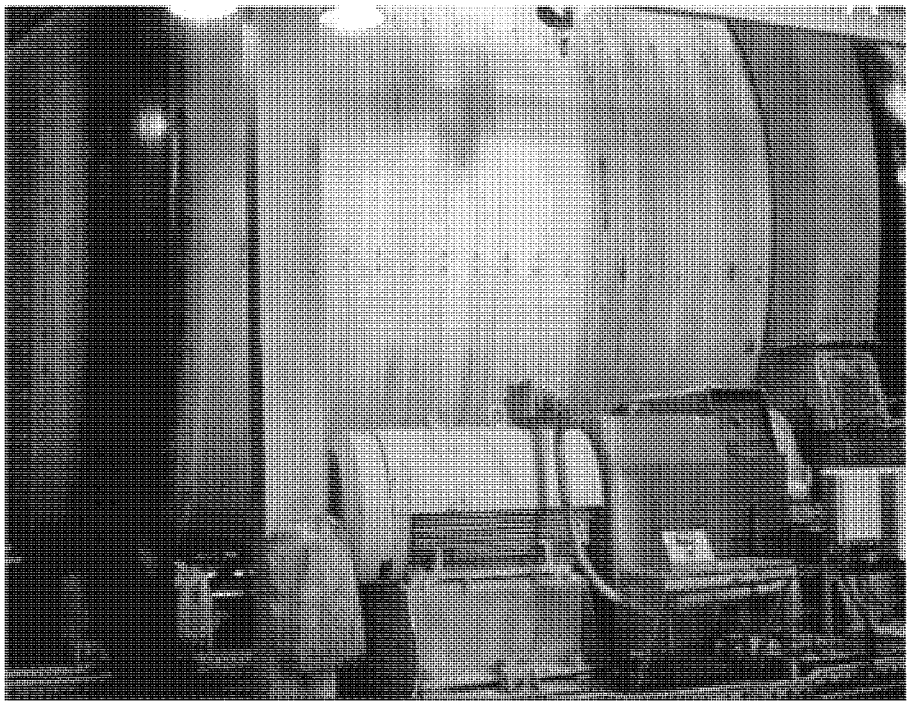

FIG. 23. Rotary drum ammoniator–granulator (courtesy: Florida Industrial and Phosphate Research Institute).

As an alternative to the conventional pre-neutralizer reactor method, the pipe cross reactor method is being used to an increasing extent, since it offers various technical and commercial advantages, including reduced energy consumption. A length of pipe incorporating a pipe cross or pipe tee is installed within a rotary drum granulator. Ammonia is introduced into the cross or tee in the direction of the horizontal axis. Phosphoric acid is introduced through the mixer head in a direction perpendicular to the flow of ammonia. The reaction between the ammonia and the phosphoric acid is continued to the point of producing MAP, which is then discharged as a melt or slurry inside the granulator.

The granulated product, containing 2–3% water, is dried using hot air in a co-current rotary drum dryer. The dried product is then screened to separate out grains in the size range 1–4 mm. The precise size of grain produced depends on market requirements. The product is conveyed to a rotary drum cooler, where it cools from 70°C to about 40°C, and is then conveyed to a storage building. Oversize and undersize material from the screening step, together with residual on-size material, are recycled back to the granulator after pulverizing where necessary. In the

ED_005285_00000684-00096

FIG. 24. Storage warehouse — product delivered by conveyor system (courtesy: Florida Industrial and Phosphate Research Institute).

post-granulation stage, the product is coated with, for example, vegetable oil to prevent airborne dust generation before being conveyed to the storage bins. In preparation for shipping, the granulated products are moved to storage areas by conveyors or by workers using large mobile equipment (see Figs 24 and 25). Workers collect spillages using smaller equipment or by hand with shovels. The products are shipped in bags, trucks, freight cars (see Fig. 26), barges or large ocean-going ships. MAP generally offers two NPK fertilizer grades: 11-52-0 and 10-50-0, the numerical values referring to the relative proportions of total nitrogen, minimum phosphate (as available P_2O_5) and potash (K_2O), respectively. DAP has a nominal NPK grade of 18-46-0. The fertilizers are applied to the soil using conventional dry fertilizer spreaders.

6.1.2. Management of residues

The production of fertilizer generates residues within the processing equipment. Typically, these are flushed out at intervals of 2–4 weeks and sent to

ED_005285_00000684-00097

FIG. 25. Storage warehouse — payloader for shipping (courtesy: Florida Industrial and Phosphate Research Institute).

the process water recycling system, which may form part of the water management system for phosphoric acid production.

There is always some spillage of dry product during production. While every attempt is made to return spillage to the production process, sometimes the presence of water makes this impractical. In that event, spillages are flushed with process water and the material sent to the process water recycling system. If the spill is large, it may also be transported by a separate vehicle or conveyor to the process water recycling system or to a nearby phosphogypsum stack.

Sources of gaseous emissions from the production of ammonium phosphate fertilizer include the reactor, granulator, dryer and cooler, as well as product sizing and material transfer operations [97]. Gaseous emissions are typically treated in the following manner, although variations exist from plant to plant:

ED_005285_00000684-00098

FIG. 26. Loading of fertilizer product into a railcar (courtesy: Florida Industrial and Phosphate Research Institute).

(a) The water vapour released during the ammoniation reaction, which accounts for a substantial portion of the water content of the slurry, contains gaseous ammonia, fluorides (such as hydrogen fluoride and silicon tetrafluoride) and ammonium phosphate particles. It is first passed through primary scrubbers that generally use weak phosphoric acid (20–30% P_2O_5) as the scrubbing liquor, principally to recover ammonia and particulates for recycling back to the process. It is then passed through secondary scrubbers that generally use recycled process water to remove fluorides. The effluent from the secondary scrubbers is returned to the process water recycling system.

(b) Exhaust gases from the dryer and cooler, as well as those from product sizing and material transfer operations, also contain ammonia, fluorides and particulates. These streams are treated in the same way as those from the ammoniation reaction, except that they are first passed through cyclones to remove the majority of the particulates.

6.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

The phosphoric acid feedstock contains most of the uranium but very little of the radium originating from the phosphate rock (see Section 5.2). This radionuclide composition is reflected in the dry fertilizer products MAP and DAP [47]. Radionuclide activity concentrations in MAP and DAP dry product and NPK fertilizers are given in Table 22. The reported concentrations of ^{238}U in ammonium phosphate fertilizers produced in different countries generally lie in the range 0.3–3 Bq/g, but in most cases the activity concentration lies in the range 1–2 Bq/g. As expected, the concentration of ^{226}Ra is much lower and is in the range 0.01–0.1 Bq/g. The presence of low levels of ^{232}Th in MAP and DAP is also indicated. Some of the compound fertilizers with different NPK compositions manufactured by mixing with various proportions of potassium salts showed lower activity concentrations of ^{238}U, possibly due to dilution. However, a similar trend is not visible in the case of ^{226}Ra levels.

A comparision of the activity concentration in MAP and DAP bulk product and associated dust particles is given in Table 23. The ^{238}U, ^{226}Ra and ^{210}Pb radioactivity concentrations in bulk product and settled dust from central Florida, USA, are 2.33–4.15 Bq/g, 0.03–0.06 Bq/g and 0.25–0.33 Bq/g, respectively. No significant differences in the concentrations of ^{238}U and ^{226}Ra are found between dry product, settled dust and airborne particles. In the case of ^{210}Pb, however, elevated concentrations (up to 3.2 Bq/g) are found in airborne dust particles, probably due to the attachment of ambient airborne radon decay products.

6.3. OCCUPATIONAL EXPOSURE

6.3.1. Gamma radiation

Doses from external exposure to gamma radiation were assessed at fertilizer plants in central Florida, USA, using individual monitoring with LiF TLDs and Al_2O_3:C OSLDs [53]. The plants produce mainly MAP and DAP, although a small amount of TSP was also produced. The mean annual effective dose was found to be in the range 0.081–0.171 mSv for workers in dry product areas and 0.122–0.197 mSv for workers in shipping and dispatch areas. Investigations have also been carried out at plants in Huelva, Spain, on exposure to gamma radiation and the annual effective dose was found to be in the range 0.076–0.134 mSv [102]. Doses received by workers as a result of external gamma exposure at a fertilizer plant in Poland were assessed using a pressurized ion chamber and LiF TLDs deployed at fixed locations [91]. The mean annual effective dose was found to be 0.10 mSv.

TABLE 23. ACTIVITY CONCENTRATIONS IN AMMONIUM PHOSPHATE FERTILIZER: COMPARISON OF BULK PRODUCT WITH DUST PARTICLES

Material	Mean activity concentration (Bq/g)		
	U-238	Ra-226	Pb-210
MAP, central Florida, USA:			
Bulk product	2.33	0.06	0.31
Settled dust	2.62	0.04	0.33
Airborne particles ≤100 μm	1.84	0.10	2.31
Airborne particles ≤10 μm	2.04	0.14	3.21
DAP, central Florida, USA:			
Bulk product	3.33	0.04	0.25
Settled dust	4.15	0.03	0.34
Airborne particles ≤100 μm	2.42	0.07	0.60
Airborne particles ≤10 μm	2.57	0.09	0.96
DAP, northern Florida, USA:			
Bulk product	0.94	0.02	
Airborne particles ≤100 μm	1.32	0.04	0.64
Airborne particles ≤10 μm	1.09	0.03	0.94

6.3.2. Inhalation of radionuclides in airborne dust

The inhalation of airborne dust is the predominant exposure pathway [46, 53]. The granulation process generates a considerable amount of dust in the form of crushed dry granulator material, leading to the possibility of this dust being inhaled by workers engaged in activities such as sampling, cleanup of spillage and manual handling. The application of an anti-dust coating to the product reduces the potential for dust generation during subsequent storage and shipping.

Detailed studies on particle size characterization of aerosols and experimental results on lung fluid solubilities have been reported from central Florida phosphate facilities [106–108]. Size measurements indicate that the aerosols do not follow a lognormal distribution and that the particle mass is increasingly concentrated in larger particle sizes in the granulation process locations. It was also noted that the values depend largely on mechanical disturbances by the movement of vehicles and other equipment, ventilation,

ED_005285_00000684-00102

structure of the buildings and operational systems, including granulators, screeners, dryers and conveyors. The samples were collected using a multistage cascade impactor sampler and a high volume sampler at a flow rate of 1130 L/min. The mean airborne dust concentration in the granulation area was 7.2 mg/m^3 and about 55% of the total mass was dominated by large (>20 μm) particles [107].

The lung fluid solubilities of uranium, thorium and lead in fertilizer dust particles (predominantly MAP and DAP) were measured using an in vitro technique involving simulated lung fluid with a neutral pH (7.2–7.4) matching that of the fluid lining the lung. Most of the phosphate, the main constituent of the dust particles, dissolved rapidly in the simulated lung fluid. However, uranium, thorium and lead dissolved less rapidly than the surrounding matrix [109]. The solubilities were found to be relatively independent of the product type or particle size. The most appropriate lung absorption classes determined from these lung solubility measurements were M for uranium and lead and S for thorium, according to the classification of lung absorption types by the ICRP [110]. The lung fluid solubility measurements were supplemented by additional measurements using a simulated lung fluid with an acidic pH (4.5–5.5) to match that of phagolysosomal fluid. The dissolution rate for ^{230}Th under these more acidic conditions was found to be more than 300 times higher than that under neutral conditions. More details on the lung fluid solubility studies reported from the Florida phosphate industry are provided in Annex I.

Annual committed effective doses received by workers from the inhalation of airborne dust in plants in central Florida, USA, were assessed [109] using the ICRP respiratory tract model described in Ref. [37], the particle size measurements reported in Refs [106–108] and the lung solubility measurements reported in Ref. [109]. An annual exposure period of 2000 h was assumed.[18] The results of the assessment are summarized in Table 24.

In phosphate plants in Poland, airborne dust concentrations have been reported as being quite high (3.0–13.5 mg/m^3) [91]. These values were obtained from routine measurements at several locations, including phosphoric acid production and multi-compound fertilizer manufacturing plants. Although these dust concentrations were reported for both phosphoric acid and fertilizer plants, it is likely that they related mostly to fertilizer plants because of the dry nature of the process. Inhalation doses received by workers were assessed from the dust

[18] This annual exposure period is very conservative, since a large portion of the working shift was reported to be spent in the control room or at some other non-dusty location. It has been suggested that a future dose assessment should be based on a more realistic annual exposure period of 500–800 h.

ED_005285_00000684-00103

TABLE 24. DOSES RECEIVED BY WORKERS VIA INHALATION OF AIRBORNE DUST IN AMMONIUM PHOSPHATE PLANTS, FLORIDA, USA [53]

Work site	Mean annual committed effective dose (mSv)	
	Based on solubility in neutral simulated lung fluid	Based on solubility in acidic simulated lung fluid
Granulator area	0.14	0.25
Storage area	0.10	0.16
Shipping area	0.03	0.05

concentrations, assuming an AMAD of 1 μm. The radionuclide activity concentrations in the dust were not measured, but were, instead, estimated from the values measured for raw materials and fertilizers in the workplace. The assessed doses were in the range 2.9–5.6 mSv/a. It was reported that the lack of sufficient data for sensitive inhalation dose parameters had necessitated the application of conservative assumptions and probably resulted in the doses being overestimated.

6.3.3. Inhalation of radon

Radon concentration measurements have been made in plants in Huelva, Spain [94], and Florida, USA [53]. In all cases, the radon concentrations were at normal background levels. Consequently, inhalation of radon by workers is not regarded as a significant exposure pathway.

6.3.4. Total effective dose

The total annual doses received by workers in ammonium phosphate fertilizer plants can be estimated by summing the gamma doses reported in Section 6.3.1 and the dust inhalation doses given in Table 24. The results are given in Table 25 and show that a worker receives, at most, a dose of a few tenths of a millisievert per year.

ED_005285_00000684-00104

TABLE 25. TOTAL DOSES RECEIVED BY WORKERS IN AMMONIUM PHOSPHATE FERTILIZER PLANTS, FLORIDA, USA

Work site	Total annual committed effective dose (mSv)	
	Minimum	Maximum
Dry product areas	0.22	0.42
Storage areas	0.22	0.36
Shipping areas	0.15	0.25

6.4. PUBLIC EXPOSURE

6.4.1. Fertilizer production

Public exposure may arise as a result of airborne dust emissions, disposal of spillages of solid material, storm water runoff contaminated by spillages and other inadvertent discharges caused by operating factors. These can be minimized by good housekeeping procedures, including, in particular, the prompt cleanup of spillages of process material. Control of spillage also brings economic benefit by retaining valuable product material. Provided that such measures are adopted, exposure of members of the public is likely to be insignificant.

6.4.2. Fertilizer use

As the use of fertilizer is subject to the requirements for existing exposure situations (see Ref. [2] and Section 3.1.1), agricultural workers exposed to phosphate fertilizer should be treated as members of the public. Exposures may vary widely from place to place depending upon the application rate of fertilizers and local environmental conditions. In an investigation carried out in Germany, the average dose received during the application of fertilizer was 0.6 μSv/a and the maximum likely dose was 4 μSv/a [59]. An investigation was also carried out in South Africa on the use of fertilizers produced from igneous phosphate rock [111]. A detailed assessment of the doses received by agricultural workers, considering all pathways of exposure, found that the doses never exceeded 10 μSv/a, based on conservative assumptions, including worst case scenarios. Evidence suggests that public exposure attributable to the use of ammonium phosphate fertilizers is of no significant concern.

ED_005285_00000684-00105

6.5. REGULATORY CONSIDERATIONS

The activity concentrations of radionuclides such as ^{238}U in both the phosphoric acid feedstock and the fertilizer product generally exceed 1 Bq/g. In terms of the Standards, therefore, the production of ammonium phosphate fertilizer needs to be considered for regulation as a practice. However, the evidence suggests that annual doses received by workers are consistently below 1 mSv and that there are no significant exposure pathways to members of the public. The most appropriate regulatory option for fertilizer production activities would seem to be either the granting of an exemption or a requirement for notification. This would be especially appropriate in situations where, as part of good industrial practice, basic OHS and environmental protection measures are in place, including measures for the management of process water, the containment of spillages and the control of airborne dust and discharges to the environment. The use of ammonium phosphate fertilizer does not need to be subject to any restrictions in terms of the requirements for existing exposure situations.

The radionuclide activity concentrations in the process materials and products are such that the transport of these materials would not fall within the scope of application of the Transport Regulations.

7. MANUFACTURE AND USE OF SUPERPHOSPHATE FERTILIZERS

Superphosphates represent a class of fertilizer product made by direct but partial acidulation of phosphate rock to render the phosphate mineral content largely water soluble. Various forms of insoluble apatite, which consist essentially of tricalcium phosphate, are converted to MCP using either sulphuric acid or phosphoric acid.

7.1. PROCESS DESCRIPTION

7.1.1. Single superphosphate (SSP)

SSP (known also as 'normal', 'simple' or 'ordinary' superphosphate) is a mixture of (water soluble) MCP and $CaSO_4$, with a P_2O_5 content of 16–22%. It is manufactured by reacting phosphate rock, usually a fluorapatite, with sulphuric acid. The basic chemical reaction is:

ED_005285_00000684-00106

$$Ca_{10}(PO_4)_6F_2 + 7H_2SO_4 \rightarrow 3Ca(H_2PO_4)_2 + 7CaSO_4 + 2HF$$

In contrast with the use of sulphuric acid digestion to produce phosphoric acid (see Section 5.1.1), the $CaSO_4$ produced by the digestion process is not separated out but, instead, remains as a component of the final product. There are many side reactions involving fluorine compounds, the most significant being:

$$4HF + SiO_2 \rightarrow SiF_4 + 2H_2O,$$

$$3SiF_4 + 4H_2O \rightarrow SiO_2 \cdot 2H_2O + 2H_2SiF_6$$

and

$$SiF_4 + 2HF \rightarrow H_2SiF_6$$

The production process is, in principle, very simple and dates back to the 19th century. In modern SSP plants, the phosphate rock is processed by one of two methods:

(i) The rock is dry milled to a particle size of 90–95% <150 μm and then reacted with 70–75% strength sulphuric acid in a high speed mixer; or
(ii) The rock is wet milled and the resulting slurry is reacted with 98% strength sulphuric acid, the water content of the slurry causing the acid to be diluted within the mixer.

To facilitate completion of the reaction, a slight excess of sulphuric acid is used. The exothermic nature of the reaction raises the temperature to more than 90°C. From the mixer the slurry is sent to a 'den' where it solidifies on a travelling grate or rubber belt. The solid SSP is excavated 30 min to 4 h later, the exact period depending on the temperature, the reactivity of the rock and the degree of excess acid used. The excavated material is then processed in one of two ways to produce a final product that is uniform in composition and size:

(i) The material is conveyed to a storage building (adequately ventilated to prevent the buildup of fluoride vapours), where the reaction continues for 2–6 weeks in a process called 'curing', after which the hardened and cured product is milled and screened before shipment as 'powder SSP'; or
(ii) The material is converted into a granular form using water and steam and then screened to separate out granules of the required size; oversize granules are milled and, together with the undersize granules, returned to the granulation step.

ED_005285_00000684-00107

Most modern plants are completely mechanized. A typical production unit requires as few as two or three operators. Plants are generally regulated with regard to HF and SiF_4 emissions. By means of a water scrubber, HF generated by the acid digestion reaction and sometimes also fluoride vapours released within storage buildings are captured and returned with the scrubber water to the process water recycling system.

7.1.2. TSP

TSP consists entirely of MCP, with an available P_2O_5 content of 43–48%. It is produced by reacting phosphate rock (fluorapatite) with phosphoric acid (and sometimes sulphuric acid) and is manufactured in two basic product forms, the first being known as non-granular or 'run-of-pile' TSP (ROP-TSP) and the second as granular TSP (GTSP). The larger, more uniform particle size of GTSP gives it improved storage and handling characteristics. The basic chemical reaction is:

$$Ca_{10}(PO_4)_6F_2 + 12H_3PO_4 + 9H_2O \rightarrow 9Ca(H_2PO_4)_2 \cdot H_2O + CaF_2$$

Side reactions involving fluorine compounds include:

$$2CaF_2 + 4H_3PO_4 + SiO_2 \rightarrow SiF_4 + 2Ca(H_2PO_4)_2 + 2H_2O$$

and

$$3SiF_4 + 4H_2O \rightarrow SiO_2 \cdot 2H_2O + 2H_2SiF_6$$

The manufacturing process for ROP-TSP is similar to that for SSP (see Section 7.1.1). Phosphate rock and concentrated phosphoric acid (50–54% P_2O_5) are brought together in a cone or other high speed mixer, which discharges directly into a continuously moving 'den'. A very dense slurry is produced, which, after solidifying into a porous, honeycomb-like mass, is pulverized by a rotary cutter into particles of various sizes. The particles are conveyed to the storage area for pile curing where the reaction continues for 3–5 weeks. The cured material is excavated and shipped as ROP-TSP or is converted into GTSP by treatment with water and steam in a granulator, followed by drying and screening.

GTSP is also manufactured directly by reacting milled phosphate rock with lower strength phosphoric acid (32–40% P_2O_5). The lower acid concentration allows the reaction products to be maintained in a fluid state throughout the mixing period of 1–2 h. The resulting slurry is mixed with a large amount of

ED_005285_00000684-00108

dried, fine granules that have been recycled back from the product screening step. These granules become enlarged as a result of coating with the slurry. The coated granules are dried in a rotary dryer, with the heat of the dryer causing the chemical reaction to be accelerated towards completion. The dried granules are then sized using vibrating screens. Product size granules separated out by the screens are cooled in a countercurrent rotary drum or fluidized bed air cooler and then sent to a storage pile for curing. After a minimum curing period of 3–5 d, the granules are ready for bagging and shipping. Granules not meeting the size specifications are recycled back to the process (after crushing, in the case of oversize granules).

Residues accumulate in the processing equipment over time. These are removed periodically, typically every 2–4 weeks, and are sent to the process water recycling system.

Airborne particles are generated during the unloading, grinding, storage and transfer of ground phosphate rock and are controlled by air extraction systems and baghouse collectors. The baghouse cloth filters are reported to have removal efficiencies of over 99%. The collected particles are recycled back to the process. Gaseous fluorides (SiF_4 and HF) and airborne particles are generated by the acidulation reaction, although fluoride emanation from the storage pile in the curing building is relatively small because the acidulation reaction is, at that stage, almost complete. Airborne particles are also generated by the dryer, screens, cooler, mills and transfer conveyors. Emissions of fluorides and particles from the production area and curing building are controlled by scrubbing the off-gases with recycled pond water in cyclonic scrubbers. Emissions from the dryer, cooler, screens, mills, product transfer systems and product storage building are sent to a cyclone separator for removal of a portion of the dust before going to wet scrubbers to remove fluorides. Tail gas wet scrubbers perform final cleanup of the plant off-gases. The efficiencies of fluoride control are 90–99%, while an efficiency of 98% is achievable for particulate control. Used scrubber water is normally sent to the process water recycling system.

7.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

The reaction of phosphate rock with either sulphuric acid or phosphoric acid leading directly to a fertilizer product does not cause any of the radioactive material to precipitate selectively or concentrate in any manner. The radionuclide content of the fertilizer product reflects the combined radionuclide content of the phosphate rock and, where used, phosphoric acid [47]. Consequently, the activity concentrations of ^{238}U series radionuclides in SSP are all about 1 Bq/g, approximately 30% lower than those in the phosphate rock owing to the mass

ED_005285_00000684-00109

increase from the addition of sulphuric acid. The ^{238}U activity concentration in GTSP is typically about 2.5 Bq/g, some 70% higher than that in the phosphate rock as a result of the addition of uranium via the phosphoric acid, while the ^{226}Ra activity concentration is about 1 Bq/g, approximately 40% lower than that in the phosphate rock. Given that the radionuclide activity concentrations in the phosphate rock and, where used, phosphoric acid are themselves quite moderate, the consequences of radionuclide dilution (SSP) or concentration (^{238}U in GTSP) are, for most rock sources, not of any great significance. Actual activity concentration data reported for several countries are given in Table 26.

7.3. OCCUPATIONAL EXPOSURE

Occupational exposures were investigated in four plants in Poland producing SSP, TSP and NPK fertilizers [91]. Doses from external exposure to gamma radiation were assessed using a pressurized ion chamber and LiF TLDs deployed at fixed locations. The mean annual effective dose from gamma radiation was found to be 0.05 mSv for the SSP plant and 0.20 mSv for the TSP plant.

TABLE 26. RADIONUCLIDE ACTIVITY CONCENTRATIONS IN SUPERPHOSPHATE FERTILIZERS

Material	Mean activity concentration (Bq/g)		
	U-238	Ra-226	Pb-210
SSP:			
Florida, USA [50]	0.74	0.79	
Belgium [50]	1.10	0.91	
Germany [50]	0.52	0.52

Poland [91]	1.79	0.86	
Brazil [100]	0.22	0.12	0.20

ED_005285_00000684-00110

Inhalation dose assessments were carried out in phosphate fertilizer plants in Florida, USA [53]. Using various assumptions, the average annual committed effective dose from dust inhalation was conservatively estimated to be <0.05 mSv in the dry product areas and <0.8 mSv in the shipping and storage areas. These inhalation doses, although conservative, could be regarded as being reasonably representative of those received in SSP and TSP plants. Follow-up studies, aimed at removing the need for some of the conservative assumptions, indicated that the inhalation doses were likely to be lower, and well below 1 mSv/a [112].

7.4. PUBLIC EXPOSURE

7.4.1. Fertilizer production

During the fertilizer production process, it is evident that airborne emissions of fluorides and particulate matter are controlled very effectively. In addition, the small amounts of solid residues generated in these emission control systems and elsewhere are managed as part of the process water recycling system. It can be concluded that these pollution control measures will also be effective in controlling the release of radionuclides to the environment. Given that there are no other obvious exposure pathways to the public during the manufacturing process, it can be concluded that public exposure attributable to superphosphate fertilizer production is of no significant concern.

7.4.2. Fertilizer use

There is a potential for exposure of agricultural workers (who, in terms of the requirements for existing exposure situations [2], are regarded as members of the public) as a result of the use of superphosphate fertilizers. However, the lower activity concentrations in supherphosphate fertilizers compared with those in ammonium phosphate fertilizers (see Section 6) suggest that the doses are likely to be insignificant.

7.5. REGULATORY CONSIDERATIONS

The activity concentrations of radionuclides such as ^{238}U in the phosphoric acid feedstock and in the GTSP fertilizer product generally exceed 1 Bq/g. In terms of the Standards, therefore, the production and use of superphosphate fertilizer needs to be considered for regulation as a practice. However, the annual doses received by workers are consistently below 1 mSv and there are no

ED_005285_00000684-00111

significant exposure pathways to members of the public. The most appropriate regulatory option for superphosphate fertilizer production activities would seem to be either the granting of an exemption or a requirement for notification. This would be especially appropriate in situations where, as part of good industrial practice, basic OHS and environmental protection measures are in place, including measures for the management of process water, the containment of spillages and the control of airborne dust and discharges to the environment. The use of superphosphate fertilizer would not need to be subject to any restrictions in terms of the requirements for existing exposure situations.

The radionuclide activity concentrations in the process materials and products are such that the transport of these materials would not fall within the scope of application of the Transport Regulations.

8. MANUFACTURE AND USE OF NITROPHOSPHATE FERTILIZERS (NITRIC ACID DIGESTION)

8.1. PROCESS DESCRIPTION

The treatment of phosphate rock with nitric acid using a process known as the 'ODDA process' produces phosphate fertilizer and calcium nitrate, which is also a fertilizer. The properties of the fertilizer products are such that they may not be as broadly competitive as other fertilizers, but their specialized nature has made them the subject of growing interest. Plants using this technology have operated in Finland, Germany, Italy, Netherlands, Norway, Romania and Sweden [113, 114]. Some plants in Pakistan also use this technology to produce nitrophosphate fertilizer [115].

The main reaction between nitric acid and phosphate rock is as follows:

$$Ca_{10}(PO_4)_6F_2 + 20HNO_3 \rightarrow 6H_3PO_4 + 10Ca(NO_3)_2 + 2HF$$

After the separation of the insoluble material, phosphoric acid is neutralized with ammonia to produce a fertilizer. If the calcium nitrate is left in the solution, it reverts to dicalcium phosphate upon ammoniation as per the following reaction:

$$2H_3PO_4 + Ca(NO_3)_2 + 4NH_3 \rightarrow CaHPO_4 + (NH_4)_2HPO_4 + 2NH_4NO_3$$

ED_005285_00000684-00112

On heating the paste-like mixture to drive off the free moisture, the water solubility of the phosphate in the dried residue is greatly reduced due to the formation of dicalcium phosphate, as described by the following equation:

$$Ca(H_2PO_4)_2 + 2Ca(NO_3)_2 \rightarrow 2CaHPO_4 + Ca(NO_3)_2 + 2HNO_3$$

The nitric acid evolved during this step corresponds to approximately 25% of the nitric acid originally added. The dried product contains phosphate and nitrogen but the phosphate is of low solubility. The calcium nitrate content is sufficient to give the material undesirable hygroscopic properties and the sticky, pasty product is not well suited for shipment or for spreading as a dry bulk fertilizer [116, 117]. The properties can be improved by deep cooling the mixture and precipitating some of the calcium nitrate.

A more acceptable product is obtained if the mixture of phosphoric acid, calcium phosphate and calcium nitrate, with or without the partial removal of calcium nitrate, is treated with ammonia, although ammoniation causes the calcium to form a citrate soluble calcium phosphate [113] rather than the water soluble phosphates that are present in MAP or DAP (see Section 6). Dicalcium phosphate is usually insoluble in water but soluble in ammonium citrate solution and is, therefore, regarded as a source of 'available' P_2O_5. However, fertilizer specification often requires water solubility and this type of product is limited to 50% water solubility of the P_2O_5. The calcium can also be removed by precipitation with sulphate, the sulphate being added as sulphuric acid or ammonium sulphate [118], leaving only the phosphoric acid component of the mixture. The reaction with sulphuric acid produces nitric acid and phosphogypsum (calcium sulphate), according to the following reaction:

$$Ca(NO_3)_2 + H_2SO_4 \rightarrow 2HNO_3 + 2CaSO_4$$

The nitric acid produced by the reaction may be recovered and recycled back to the process. However, as a means of producing phosphoric acid, the nitric acid process has no significant advantage over the more usual process involving the digestion of the phosphate rock with sulphuric acid.

A variety of fertilizers is produced from the addition of compounds such as calcium carbonate (lime), carbon dioxide, ammonia, potassium chloride or potassium sulphate. These include calcium ammonium nitrate, granular ammonium nitrate, granular ammonium sulphate with added potassium and various granular NPK products. A simplified diagram of the various process steps employed to produce ammonium nitrate fertilizers (calcium ammonium nitrate and NPK) is given in Fig. 27.

ED_005285_00000684-00113

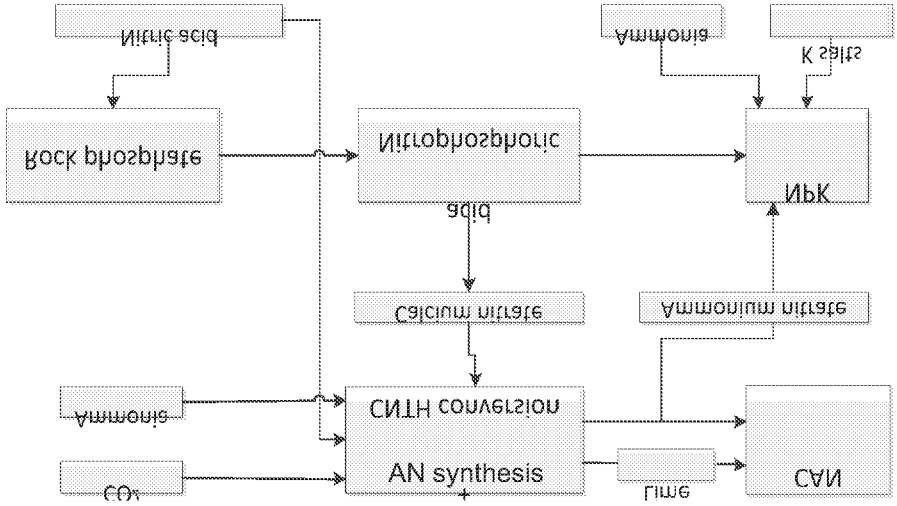

FIG. 27. Nitric acid route to nitrophosphate fertilizer production (CNTH: calcium nitrate tetrahydrate; AN: ammonium nitrate; CAN: calcium ammonium nitrate fertilizer; NPK: nitrogen–phosphorus–potassium fertilizer) [117].

The nitric acid processing route generates gaseous emissions of NO_x, NH_3 and HF to the atmosphere, as well as small amounts of silica (sand). Depending on radionuclide activity concentrations, the sand may be used for construction purposes.

8.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

All the radioactivity in the phosphate rock feedstock ends up in the fertilizer products, although at lower activity concentrations because of dilution due to the addition of nitric acid, ammonia and other compounds. The precipitation of calcium nitrate, where practised, does not affect this situation because the radioactivity remains with the phosphoric acid during the precipitation step. Should the calcium be precipitated by the addition of sulphuric acid, the phosphogypsum so produced would contain most of the radium but very little of the uranium. The actual activity concentrations reported from a few countries where nitrophosphate fertilizers have been produced are given in Table 27. The reported ^{238}U activity concentrations are in a narrow range and typically about 0.4 Bq/g. One of the plants in Belgium produced nitrophosphate fertilizers for more than three decades and the typical radium activity concentration in the fertilizers never exceeded 0.1 Bq/g [95].

ED_005285_00000684-00114

TABLE 27. RADIONUCLIDE ACTIVITY CONCENTRATIONS IN NITROPHOSPHATE FERTILIZERS

Country	Mean activity concentration (Bq/g)		
	U-238	Ra-226	Pb-210
Italy [114]	0.37	0.12	0.21
Belgium [95]		0.10	
Germany [50]	0.40	0.30	
Romania [105]	0.26–0.36	0.26–0.36	
Pakistan [115]		0.39	

8.3. OCCUPATIONAL EXPOSURE

Gamma dose rates have been measured in production areas and raw material and end product warehouses in a nitrophosphate fertilizer plant in Italy [119]. The dose rates in the production areas were 0.15–0.2 μSv/h, comparable with background levels. Slightly elevated dose rates in the range 0.12–1.10 μSv/h were measured in the end product storage areas and were mainly due to the high percentage of ^{40}K present in the products. Data were also reported from the plant on the mass concentrations of airborne dust at several locations in the production areas and storage areas. The mean dust levels were in the range 0.1–2.1 mg/m^3 in the hoppers, reactors, granulation and other areas of the production unit. Higher levels of dust were found in the raw material warehouse and fertilizer product storage areas, where the mean concentrations were 5.4 and 1.7 mg/m^3, respectively.

The annual effective doses received by workers from gamma radiation and inhalation of airborne dust reported in Ref. [119] are summarized in Table 28. These estimates are based on a conservative assumption of the periods spent by the workers in various work locations and probably reflect an upper estimate. Summing of the doses from external gamma exposure and inhalation of airborne dust gives total annual effective doses in the range 0.3–0.7 mSv.

Radon concentrations were also reported from the plant. Measurements showed radon concentrations to be in the range 40–60 Bq/m^3 in production areas, comparable with the natural background concentration at the site. However, elevated levels, up to 210 Bq/m^3, were found in the raw material and end product warehouse, especially during the winter season.

ED_005285_00000684-00115

TABLE 28. ESTIMATED DOSES RECEIVED BY WORKERS IN A NITROPHOSPHATE PLANT [119]

Work site	Mean annual effective dose (mSv)			
	Gamma radiation	Dust inhalation	Dust ingestion	Total
Raw material storage areas	0.4	0.04	0.006	0.45
Production area	0.3	0.03	0.01	0.34
Fertilizer product bagging	0.4	0.3	0.013	0.71
Pallet control	0.4	0.12	0.013	0.53
Product storage areas	0.6	0.13	0.013	0.74
Product bagging and warehouses	0.3	0.12	0.013	0.43

8.4. PUBLIC EXPOSURE

8.4.1. Fertilizer production

Using conservative assumptions, the maximum annual effective dose received by individuals living near a nitrophosphate fertilizer manufacturing plant in Italy was assessed [119]. The maximum annual inhalation dose from airborne dust was about 4 μSv, based on the predicted ground level air concentration at a distance of 0.2 km from the plant. The contribution of external gamma exposure was negligible at the site.

8.4.2. Fertilizer use

From the radionuclide activity concentrations reported in Table 27, it can be concluded that the exposure of agricultural workers (who, in terms of the requirements for existing exposure situations [2], are regarded as members of the public) as a result of the use of nitrophosphate fertilizers is of no significant concern.

8.5. REGULATORY CONSIDERATIONS

The activity concentrations of radionuclides such as ^{238}U in the phosphoric acid feedstock generally exceed 1 Bq/g, whereas in the nitrophosphate fertilizer

ED_005285_00000684-00116

product, the activity concentration is below 1 Bq/g. In terms of the Standards, therefore, the production of nitrophosphate fertilizer needs to be considered for regulation as a practice. However, the evidence suggests that annual doses received by workers are consistently below 1 mSv and that there are no significant exposure pathways to members of the public. The most appropriate regulatory option for fertilizer production activities would seem to be either the granting of an exemption or a requirement for notification. This would be especially appropriate in situations where, as part of good industrial practice, basic OHS and environmental protection measures are in place, including measures for the management of process water, the containment of spillages and the control of airborne dust and discharges to the environment. The use of nitrophosphate fertilizer does not need to be subject to any restrictions in terms of the requirements for existing exposure situations.

The radionuclide activity concentrations in the process materials and products are such that the transport of these materials would not fall within the scope of application of the Transport Regulations.

9. MANUFACTURE AND USE OF ANIMAL FEED PHOSPHATES

The phosphate industry produces animal feed additives that contain various mixtures of phosphates and other nutrients, especially nitrogen, as well as micronutrients such as magnesium, sulphur and zinc. The phosphate content consists mainly of calcium phosphate in one form or another, with calcium being particularly effective as an animal feed supplement when used in conjunction with phosphorus. Since phosphate ores contain fluorine, which is toxic to animals, it is necessary to ensure that the fluorine content of the product is very low (less than 1% of the phosphorus content). Two basic types of animal feed phosphate are produced:

(i) The first type contains tricalcium phosphate and is therefore marketed under the name TCP. It is also known as defluorinated phosphate rock. TCP is relatively high in calcium and derives its phosphorus content from a mixture of phosphate rock concentrate and phosphoric acid. It contains a minimum of 30% calcium and 18% phosphorus and can be represented by the chemical formula $Ca_3(PO_4)_2 \cdot Na_3PO_4 \cdot Ca_2SiO_4$.

ED_005285_00000684-00117

(ii) The second type, the more popular of the two, contains MCP, dicalcium phosphate or mixtures of the two in various proportions. The products are marketed as a range of products referred to generically as MCP–DCP or 'granular DCP', or more specifically as MCP or DCP. These products are lower in calcium than TCP and derive their phosphorus content only from phosphoric acid or phosphate rock, depending on the production process used. Products marketed as MCP contain 15–20% calcium and 21% phosphorus, while products marketed as DCP contain 18–24% calcium and 18.5% phosphorus. MCP is also marketed as a fertilizer.

9.1. PROCESS DESCRIPTION

9.1.1. TCP animal feed

TCP is manufactured by mixing phosphate rock with phosphoric acid and sodium hydroxide and calcining the mixture at a temperature of 1370–1510°C. These conditions cause the fluorine in the feedstock materials to be driven off in the form of gaseous HF and convert the phosphate mineral into a biologically available form. Depending on the type of calciner used, steam may need to be added to facilitate the defluorination reaction. After cooling, the calcined material is granulated, dried and screened to produce TCP granules of the required size.

9.1.2. MCP–DCP animal feed

9.1.2.1. Reaction of phosphoric acid with limestone

Most MCP–DCP animal feed phosphates are produced by reacting defluorinated phosphoric acid (38–42% P_2O_5) with high quality finely ground limestone. Typically, the limestone contains 93–97% $CaCO_3$ and its particle size distribution is such that about 90% passes through a 200 Tyler mesh screen (0.075 mm). The neutralization of phosphoric acid with limestone can produce five different forms of calcium phosphate: $Ca(H_2PO_4)_2$; $Ca(H_2PO_4)_2 \cdot H_2O$; $CaHPO_4$; $CaHPO_4 \cdot 2H_2O$; and a crystalline product of variable composition having the X ray diffraction pattern of an apatite in which $Ca_3(PO_4)_2$ has been arbitrarily singled out from the hydroxyapatite family. The reactions with the limestone are as follows:

$$2H_3PO_4 + CaCO_3 \rightarrow Ca(H_2PO_4)_2 \cdot H_2O + CO_2$$

$$Ca(H_2PO_4)_2 + CaCO_3 \rightarrow 2CaHPO_4 + CO_2 + H_2O$$

ED_005285_00000684-00118

$$H_3PO_4 + CaCO_3 \rightarrow CaHPO_4 + CO_2 + H_2O$$

$$H_3PO_4 + CaCO_3 + H_2O \rightarrow CaHPO_4 \cdot 2H_2O + CO_2$$

There is some evidence that, at moderate temperatures, the first solid to appear is dicalcium phosphate dihydrate. This hydrolyses readily to MCP monohydrate and tricalcium phosphate (apatite), according to the reaction:

$$4CaHPO_4 \cdot 2H_2O \leftrightarrow Ca(H_2PO_4)_2 \cdot H_2O + Ca_3(PO_4)_2 + 8H_2O$$

In the presence of water, MCP monohydrate hydrolyses to give dicalcium phosphate and phosphoric acid, according to the reaction:

$$Ca(H_2PO_4)_2 \cdot H_2O \leftrightarrow CaHPO_4 + H_3PO_4 + H_2O$$

The reaction between the phosphoric acid and limestone is carried out in a high speed mixer followed by a granulator and is allowed to proceed nearly to completion in order to release as much carbon dioxide as possible. Material from the granulator is dried and then conveyed to sizing screens where it is separated into a product size fraction, an oversize fraction and fines. The oversize fraction is ground and, together with the fines from the screens and from the dust collection systems on the dryer, cooler and other equipment, is recycled to the granulator to provide seed nuclei for the granulation process. The on-size product from the screen is cooled and sent to storage.

A new method of producing dicalcium phosphate placed product on the market for the first time in 2009. The new method uses a previously unexploited part of the existing wet-acid process [120]. The conventional pre-release process for treating acidic water in phosphogypsum stacks by neutralizing the water using lime is not effective in removing phosphates. In the new treatment process, the phosphate content is recovered and used for producing dicalcium phosphate.

9.1.2.2. Reaction of phosphate rock with hydrochloric acid

MCP and DCP may also be produced by the acidulation of phosphate rock with hydrochloric acid. The reaction generates residues in the form of HF gas and a liquid effluent charged with $CaCl_2$. For the production of MCP, the reaction proceeds as follows:

$$Ca_{10}F_2(PO_4)_6 + 14HCl + 3H_2O \rightarrow 3Ca(H_2PO_4)_2 \cdot H_2O + 7CaCl_2 + 2HF$$

ED_005285_00000684-00119

Excess calcium salts react with the liberated HF, resulting in the precipitation of insoluble CaF_2. The effluent is discharged to surface water bodies after treatment. About 0.5 t of solid waste is produced per tonne of P_2O_5. It is reported that this solid waste is deposited in stacks [85], as is the case with phosphogypsum.

For the production of DCP, phosphate rock is digested with hydrochloric acid repeatedly followed by decanting at each digestion step. The digested fraction of the phosphate rock is further treated with high quality limestone to precipitate the P_2O_5 from the solution. The white pulp generated is washed and vacuum filtered and the solid fraction is allowed to proceed to a drier to become DCP product. The liquid fraction, predominantly $CaCl_2$ effluent resulting from the filtration of the white pulp is released to a two or three step decantation and settling process and finally the residual water is treated in a water treatment facility before discharge. The undigested solid fraction is filtered and disposed of along with the water treatment sludge generated in the subsequent process steps. The liquid effluent obtained during the filtration of the sludge is usually sent to the water treatment facility where the effluent is treated along with the residual water from the DCP production line [25, 121].

9.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

It is reported in Ref. [25] that TCP contains ^{210}Pb and ^{210}Po each at an activity concentration of 0.1 Bq/g. In the case of MCP and DCP, the radionuclide compositions depend on whether production is by reacting phosphoric acid with limestone or by reacting phosphate rock with hydrochloric acid.[19] Data on radionuclide activity concentrations in MCP and DCP are given in Table 29. With regard to the phosphoric acid route, the new DCP production method described in Ref. [120] reduces the ^{238}U and ^{226}Ra concentrations in the DCP product to only 10% of the levels found in DCP produced by the more traditional method.

In the production of DCP by the hydrochloric acid route, there is an inhomogenous distribution of uranium series radionuclides between the different process outputs. The radionuclides ^{238}U and ^{210}Pb dominate in the DCP product whereas ^{230}Th and ^{210}Po dominate in the solid wastes. Although the activity concentration of ^{210}Po in the DCP is initially lower in comparison with ^{210}Pb, this

[19] The heavy metals content is also affected — the phosphoric acid route generally produces relatively high concentrations of Cd and other metals such as Mg, Al, Fe and Cr in the final DCP product, whereas the hydrochloric acid route leads to relatively high Pb and As concentrations.

ED_005285_00000684-00120

ED_005285_00000684-00121

radionuclide grows back into equilibrium with ^{210}Pb after a relatively short time. The process generates two liquid effluents together with a sludge which is mainly the water treatment sludge [25]. The radionuclide activity concentrations in these process residues are given in Table 30. Radium, being chemically similar to calcium, forms $RaCl_2$ together with the $CaCl_2$. The addition of $BaCl_2$ to the $CaCl_2$ effluent during the effluent treatment process will cause about 90% of the radium to precipitate as radium sulphate, which, together with $BaSO_4$, will end up as part of the solid waste. The ^{226}Ra activity concentration in the solid waste is reported to be in the range 2–10 Bq/g [85]. If the effluent is not treated with $BaCl_2$, the $RaCl_2$ will remain in solution during the effluent treatment process and will be discharged to surface water bodies along with the treated process water.

9.3. OCCUPATIONAL EXPOSURE

Most modern production facilities have a high degree of automation that makes it unnecessary for workers to spend much time in production areas. Gamma dose rates measured in a DCP production plant gave incremental dose rates in the range 0.1–0.2 μSv/h across different production locations. Annual effective doses received by workers through the gamma exposure pathway were estimated to be approximately 0.1 mSv [122]. Dust measurements were also reported from the plant. The main source of dust was identified as the product drying operation. Occasionally, dust was released from the containers feeding phosphate rock into the process tanks. The average dust concentration in the DCP production area was 3.5 mg/m^3 and the inhalation dose received by workers in that area was 0.07 mSv/a. It was concluded that dust could be a hazard in DCP manufacturing plants and that dust control measures and restrictions on periods of exposure to dust were important in reducing inhalation doses. Studies were also carried out to assess indoor radon in a DCP plant. No significant increase above the background levels was observed. For all exposure pathways, the annual effective doses received by workers were found to be much less than 1 mSv.

TABLE 30. RADIOACTIVITY IN RESIDUES FROM THE PRODUCTION OF DCP BY HYDROCHLORIC ACID DIGESTION OF PHOSPHATE ROCK [25]

Residue	Activity concentration (Bq/L)				
	U-238	Th-230	Ra-226	Pb-210	Po-210

Sludge	5.0–5.3	10.1–11.9	0.66–2.3	0.66–1.2	7.9–13

ED_005285_00000684-00122

9.4. PUBLIC EXPOSURE

9.4.1. Animal feed production

Measurements of gamma dose rates and radon concentrations have been reported for four stack deposits containing solid waste associated with the production of MCP by hydrochloric acid digestion [85]. The results are given in Table 31. Assuming that the measurements were made close to the stacks (the distance is not specified), it is unlikely that any significant dose would be received by a member of the public living at a reasonable distance from the stacks. The results suggest quite strongly that, for the four stacks investigated, capping had no significant effect on radon exhalation. It is difficult to determine from the results whether capping had any significant influence on gamma radiation.

In a typical phosphoric acid and fertilizer production facility, any DCP production via the phosphoric acid route is generally a small part of the total production. As a consequence, the disposal of solid waste from DCP production into the phosphogypsum stack will have negligible impact on its radiological characteristics. A detailed study was performed to assess the radiological impact on the public arising from the disposal of solid waste from DCP production over a period of more than a decade [123]. The potential for remobilization of the radionuclides and their migration into freshwater systems, surface soils, fish, fruit and vegetables was examined and no enhancement in uranium series radionuclide concentrations was observed. The annual effective dose to the public from ^{210}Pb and ^{210}Po through the ingestion of food was estimated to be 0.03 mSv, which is comparable with the background levels in the region.

TABLE 31. EXPOSURE LEVELS AT WASTE STACKS ASSOCIATED WITH THE PRODUCTION OF MCP BY DIGESTION OF PHOSPHATE ROCK WITH HYDROCHLORIC ACID [85]

Stack volume (million m^3)	Ra-226 activity concentration (Bq/g)	Capping	Exposure level		Mean exposure level per unit Ra-226 concentration	
			Gamma dose rate (μSv/h)	Radon concentration (Bq/m^3)	Gamma dose rate (μSv/h)	Radon concentration (Bq/m^3)
0.1	3–4	No	1	60	0.3	17
0.5	3–4	Yes	1	30–85	0.3	16
0.1	2–4	Yes	0.05–0.25	30–80	0.1	18
1.4	3.5–10	No	2.6	50–200	0.4	19

ED_005285_00000684-00123

9.4.2. Animal feed consumption

The use of animal feed containing radionuclides of natural origin is subject to the requirements for existing exposure situations [2]. In terms of these requirements, protective action in the form of restrictions on activity concentration might need to be considered, particularly if the reference level, typically a dose of 1 mSv/a to a member of the public, was exceeded. The activity concentrations of ^{238}U and ^{210}Pb in DCP produced via the hydrochloric acid route are elevated (see Table 29). Although DCP is diluted considerably when fed to animals, the extent to which ^{210}Pb (along with ^{210}Po, which grows back into equilibrium with ^{210}Pb) may enter the human food chain has been raised as a concern. An investigation of ^{210}Pb and ^{210}Po in chickens fed on a diet supplemented by DCP is reported in Refs [25, 121]. The chickens were fed on diets of 2.5% DCP (containing ^{210}Pb and ^{210}Po, each at an activity concentration of 0.06 Bq/g) and 5% DCP (containing ^{210}Pb and ^{210}Po, each at an activity concentration of 0.11 Bq/g). It was found that 95% of the ingested activity was excreted immediately. The remaining ^{210}Pb accumulated mostly in the bone, to an activity concentration of up to 0.012 Bq/g, while the remaining ^{210}Po accumulated in the liver (up to 0.05 Bq/g) and kidneys (up to 0.22 Bq/g). Modelling of the ingestion pathway for chicken consumption by humans gave a maximum ingestion dose of 0.011 mSv/a [25].

9.5. REGULATORY CONSIDERATIONS

Radionuclide concentrations exceeding 1 Bq/g may be found in the phosphoric acid feedstock, the phosphate rock feedstock (in TCP production), the solid waste (from the hydrochloric acid process route) and in some animal feed products. In terms of the Standards, therefore, the manufacture and use of animal feed phosphates needs to be considered for regulatory control as a practice. The results of dose assessments show that the annual doses received by workers and by members of the public do not exceed 1 mSv. However, control needs to be exercised over liquid discharges and the disposal of sludge residues. The most appropriate regulatory option for the manufacturing process would seem to be a requirement for authorization in the form of a registration. The consumption of animal feed phosphates does not need to be subject to any restrictions in terms of the requirements for existing exposure situations.

The radionuclide activity concentrations in the process materials and products are such that, with the possible exception of some solid wastes, the transport of these materials would fall outside the scope of application of the Transport Regulations.

ED_005285_00000684-00124

10. PHOSPHOGYPSUM

10.1. INTRODUCTION

The digestion of phosphate rock with sulphuric acid generates the co-products phosphoric acid and phosphogypsum (see Section 5.1.1). For every tonne of P_2O_5 produced as phosphoric acid, 4–6 t dry mass of phosphogypsum is produced. The material mass ratio is even greater in practice because of the moisture content of phosphogypsum in its freshly processed state. For instance, phosphogypsum produced from the processing of Florida phosphate rock has a dry mass of about 5.2 t and a wet mass of 6.5 t for every tonne of phosphoric acid produced. The current annual production of phosphogypsum worldwide is about 160 million t, of which 40 million t (25%) is produced in the USA. Production is increasing worldwide and could reach 200–250 million t within the next decade or two. The total amount of phosphogypsum produced up to 2006 is estimated to have been about 6 billion t, of which 2.2 billion t (37%) was produced in the USA [33].

Depending on the particular wet process method employed (see Appendix V), phosphogypsum is produced in either the dihydrate form ($CaSO_4 \cdot 2H_2O$) or the hemihydrate form ($CaSO_4 \cdot ½H_2O$). Dihydrate methods were generally favoured in the past, especially in the USA, but hemihydrate methods are now gaining in popularity since they produce phosphoric acid of a higher strength. In the presence of free water, the hemihydrate form will quite rapidly convert to the dihydrate form and, if left undisturbed, will settle into a relatively hard cemented mass.

From the initial adoption of the wet process, phosphogypsum has enjoyed a wide range of uses, especially in agricultural and construction applications. However, in view of the large quantities produced and the seasonal nature of agricultural demand, production has far exceeded demand, resulting in two main alternative management approaches for surplus phosphogypsum:

(i) Stockpiling in large, above ground containment structures known as stacks (see Fig. 28), allowing the material to be used at a later time;
(ii) Discharging to water bodies, usually large rivers, river estuaries or the sea, thus permanently disposing of the material.

Progressive changes in environmental regulation, notably within the European Union in the 1990s and more recently under the London Convention of the International Maritime Organisation [124], have largely brought the discharge of phosphogypsum to water bodies to an end, causing considerably more

ED_005285_00000684-00125

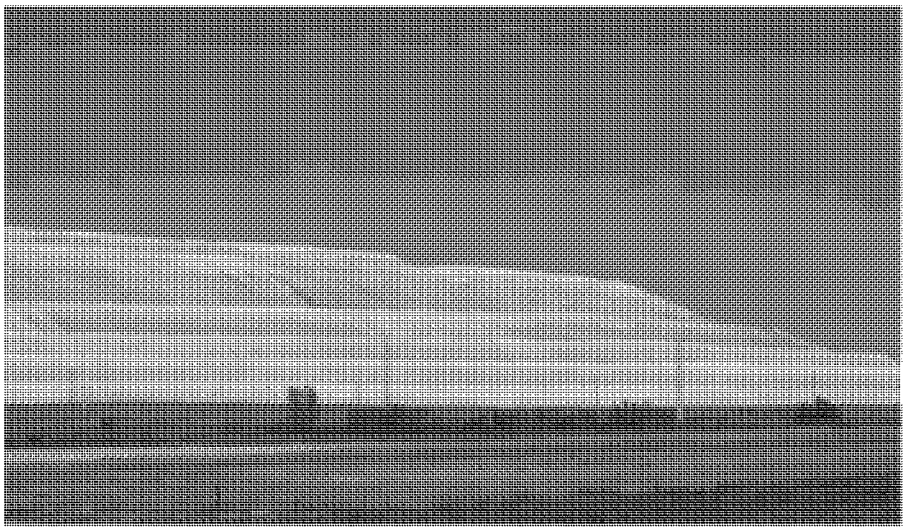

FIG. 28. A phosphogypsum stack in central Florida, USA (courtesy: Florida Industrial and Phosphate Research Institute).

phosphogypsum to be stored on land. In addition, while the use of phosphogypsum continues in several parts of the world, concerns about its radioactivity content and, to a lesser extent, its heavy metals content, have led to restrictions on the use of phosphogypsum in some markets, even though such concerns do not always have a proper scientific foundation. This has resulted in phosphogypsum stacks being, in effect, turned from short term holding piles into long term disposal facilities [125]. It has been estimated that, by 2006, a total of 2.6–3.7 billion t of phosphogypsum had been accumulated in stacks worldwide, representing 44–62% of the total amount of phosphogypsum produced up to that time. The corresponding figure for the USA (mostly in Florida) was 1.7 billion t, representing approximately half of the worldwide total. An overview of what has happened to all the phosphogypsum produced up to the year 2006 is given in Table 32. In estimating the amounts involved, a significant level of uncertainty relates to countries outside the USA concerning the amounts of phosphogypsum discharged, used or abandoned relative to the amount retained in stacks. Consequently, two estimates for these countries are given in Table 32. In the 'minimum stockpile' estimate, it is assumed that the amount of phosphogypsum that has been discharged is at the upper bound of the estimated range and that 25% of the remaining phosphogypsum has been used or abandoned, both assumptions leading to a minimum estimate of the amount stockpiled. In the 'maximum stockpile' estimate, it is assumed that the amount discharged is at the

ED_005285_00000684-00126

TABLE 32. CUMULATIVE AMOUNTS OF PHOSPHOGYPSUM UP TO 2006

Location	'Minimum stockpile' estimate		'Maximum stockpile' estimate	
	Amount (billion t)	Proportion of total (%)	Amount (billion t)	Proportion of total (%)
Stockpiled in stacks:				
USA	1.7	29	1.7	29
Other countries	0.9	16	2.0	34
Total	2.6	44	3.7	62
Discharged to water bodies:				
USA	0.5	8	0.5	8
Other countries	2.5	42	1.3	21
Total	3.0	50	1.8	29
Used or abandoned	0.3	5	0.5	8
Total amount produced	6.0	100	6.0	100

lower bound of the estimated range and that only 20% of the balance has been used or abandoned, both assumptions leading to a maximum estimate of the amount stockpiled.

Phosphogypsum is currently being added to stacks at an annual rate of about 40 million t in the USA and 90 million t elsewhere. At these rates, the total amount of phosphogypsum stored in stacks will more than double to 7–8 billion t by 2040. Most of this growth will occur in countries with developing economies, where a three- or fourfold increase can be predicted from current growth patterns. The actual growth is likely to be faster because of further reductions in discharges to water bodies and increased phosphogypsum production. Assuming a complete cessation of discharges to water bodies and an increase in phosphogypsum production from 160 to 240 million t per year, the projected total of 7–8 billion t would be reached by 2025, that is, 15 years earlier.

In addition to the phosphogypsum itself, very large volumes of highly acidic process water (also known as pond water) are associated with phosphogypsum production. Billions of litres of this water are stored on top of, and in, active stacks (see Fig. 29).

ED_005285_00000684-00127

FIG. 29. Storage of process water on a phosphogypsum stack at Huelva, Spain.

The indefinite stacking of phosphogypsum has negative impacts in terms of the engineering and environmental aspects of the stacks themselves and the associated costs and long term liabilities [83, 126]. These negative impacts were not fully appreciated in the past, but awareness of them has been growing for some time. A good example of this can be found in the USA, where the costs of closing certain older phosphogypsum stacks under locally binding regulations [127], notably in central Florida, have become very high, not least because the stacks were not designed and constructed in accordance with current standards and the use of liners to prevent groundwater contamination was not yet mandatory [128]. Furthermore, the costs of closure have fallen on taxpayers rather than on the owning companies because the stacks in question had been abandoned after the companies went into liquidation [33]. As a result, new stacks either have to be reported as liabilities in the financial statements of the owning company or subject to a minimum bond of US $150 million to cover the costs of future closure and ongoing maintenance.

This awareness of the negative impacts of indefinite stacking and the huge increases in the amounts of phosphogypsum having to be stored in stacks in the future have highlighted the need for a systematic reappraisal of the merits of, and potential for, increased use of phosphogypsum worldwide. At present, the use of phosphogypsum accounts for only a very small proportion of the amount

ED_005285_00000684-00128

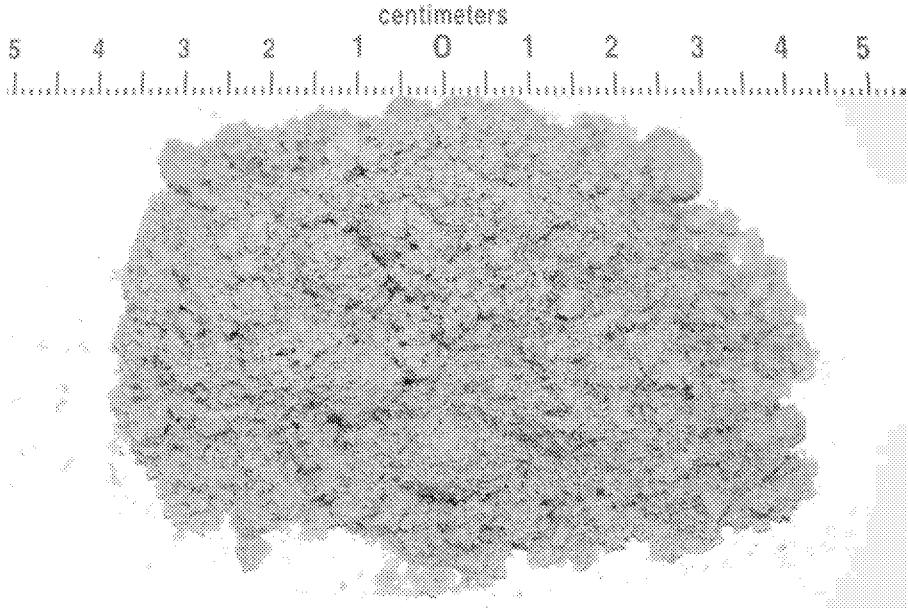

FIG. 30. Phosphogypsum.

produced (probably much less than 5%). In addition, attention is now being drawn to the potential benefits that might be derived from innovations in wet process phosphoric acid production that could reduce the operational requirements for stacks and the large ponds associated with them.

10.2. PHYSICAL AND CHEMICAL PROPERTIES

Phosphogypsum is a damp, silty or silty sand sized material (see Fig. 30). Dihydrate phosphogypsum consists primarily of silt size, relatively soft aggregates of crystals, the morphology of which depends on the source of the phosphate rock and the reaction conditions in the attack tank. The maximum particle size varies from approximately 0.5 mm (no. 40 sieve size) to 1.0 mm (no. 20 sieve size) and typically 50–75% of the material passes through a 0.075 mm (no. 200 sieve size) screen. The silty size range of dihydrate phosphogypsum classifies it as an A-4 soil in the AASHTO[20] soil classification system [129].

[20] AASHTO: American Association of State Highway and Transport Officials.

ED_005285_00000684-00129

Hemihydrate phosphogypsum generally has a larger particle size than the dihydrate form.

The moisture content is usually in the range 8–30%. For maximum density, the optimum moisture content of phosphogypsum (dihydrate or hemihydrate) lies in the range 15–20% [130]. Typical engineering properties of phosphogypsum such as density, strength, compressibility and permeability (hydraulic conductivity) can be found in Refs [130–132]. These properties are influenced not only by the characteristics of the source rock and the reaction process, but also by the method of deposition, age, location and depth within the stack in which the phosphogypsum is found. Owing to the homogeneous nature of phosphogypsum particles, the stacking process causes the material to become compacted over time. Thus, the density and strength of the material generally increase with the age of the stack and the depth within the stack, while the compressibility and permeability are likely to show a corresponding decrease. However, this effect may be compromised by the presence of voids created by dissolution channels and cavities caused by rainfall infiltration. The specific gravity of phosphogypsum produced in Florida, USA, is typically 2.3–2.6, while the upper bound of the range of dry densities is likely to lie in the range 1.47–1.67 g/cm^3, based on standard Proctor compaction (a laboratory method to determine, experimentally, the dry densities of soil) [130]. Values for phosphogypsum produced elsewhere may be slightly different. The addition of fly ash or Portland cement to phosphogypsum yields a mixture known as stabilized phosphogypsum that has slightly higher values of maximum dry density and optimum moisture content [133].

In terms of shear strength, phosphogypsum in its unconsolidated, undrained and unstabilized form typically exhibits an average internal friction angle of 32° and a cohesion value of 125 kPa. For cement stabilized phosphogypsum, the corresponding values are 28–47° and 76–179 kPa, respectively [134]. Unstabilized phosphogypsum has a permeability coefficient of 2.1–13 × 10^{-5} cm/s.

In addition to calcium sulphate, the main constituent, phosphogypsum contains alkali fluosilicates (Na_2SiF_6 and $NaKSiF_6$), chukhrovite ($Ca_4SO_4SiAlF_{13}\cdot nH_2O$) — a complex iron phosphate ($Fe_3(NH_4,K,H)H_8(PO_4)_6\cdot 6H_2O$), the majority of which is in the ammonium form — and many other possible compounds [135]. A comparison of the major constituent concentrations in phosphogypsum with those in the phosphate rock from which it is derived helps to determine the effectiveness of the sulphuric acid digestion process. A knowledge of these concentrations can also be useful in matching phosphogypsum types to end uses, especially in agricultural applications where specific nutrients, such as zinc, within the phosphogypsum can be used to remedy specific soil deficiencies [136]. Published data on the main chemical constituents of phosphogypsum are given in Appendix VI. Obviously, calcium and sulphate are the major constituents and

ED_005285_00000684-00130

together they account for up to 92% of the total content. Analyses have indicated the presence of sodium, magnesium, aluminium and iron, apart from silica and P_2O_5. The silica content of phosphogypsum is 0.5–18%, depending upon the rock source and the efficiency of the wet process. Phosphogypsum also contains fluorides, at concentrations of 0.1–1.8%. Fluoride concentrations may be significantly reduced by effective washing of the phosphogypsum before use or disposal. Since calcium sulphate is the major constituent, phosphogypsum is acidic in nature and the acidity is increased further as a result of contamination with residual phosphoric, sulphuric and hydrofluosilicic acids. For instance, phosphogypsum produced in the USA has pH values in the range 2.5–6. The aim is for most of the P_2O_5 in the phosphate rock feedstock to be recovered as phosphoric acid and, in pursuit of this aim, the trend is towards reduced amounts of residual P_2O_5 within the phosphogypsum. Nevertheless, phosphogypsum may still contain 5–20 times more phosphorus than is present in natural soils and sediments.

A knowledge of the concentrations of impurities in phosphogypsum can be important for defining technical solutions for the production of a marketable product and the consequent management and environmental policies for its storage in stacks. The concentrations of most trace elements in phosphogypsum are significantly lower than those in the source rock, even after allowing for the fact that the digestion of 1 t of rock typically produces 1.46 t of phosphogypsum. This implies that the trace elements tend to migrate with the P_2O_5 fraction to the phosphoric acid. Small amounts of radioactive elements, such as radium and uranium, and of (non-radioactive) heavy metals, such as arsenic, barium, cadmium, chromium, lead, mercury, selenium and silver, as well as phytotoxic fluoride and aluminium, are present in phosphogypsum and its pore water [76]. The concentrations of these impurities vary widely, depending on the composition of the phosphate rock used as feedstock [75, 78] and, to a lesser extent, on other factors, such as differences in operation of the processing plant [137]. With some exceptions, the concentrations of cadmium and other heavy metals in phosphogypsum derived from igneous phosphate ore tend to be lower than those in phosphogypsum derived from sedimentary ore, while the concentrations of lanthanides (rare earth elements) tend to be higher. Published data on heavy metal concentrations and rare earth elements in phosphogypsum are given in Appendix VI. It has been observed that heavy metals tend to concentrate in particles smaller than 20 μm, and it is in this size fraction that the most significant variations in concentration are to be found, depending on the characteristics of the source rock [138, 139].

ED_005285_00000684-00131

10.3. RADIONUCLIDE ACTIVITY CONCENTRATIONS

All the constituent minerals in phosphogypsum listed in Section 10.2, especially the main constituent, calcium sulphate, can be expected to exhibit radionuclide substitutions. The primary substitution compounds are thought to be sulphates in the form of radium sulphate, lead sulphate, lead disulphate, polonium disulphate and thorium disulphate. The mineral chukhrovite ($Ca_4SO_4SiAlF_{13} \cdot nH_2O$), a constituent of phosphogypsum, is known for having a relatively high radium content owing to the substitution of radium for calcium [17]. The radionuclides known or suspected of concentrating in phosphogypsum can also form fluorides, oxides, hydrides and sulphides.

A small amount of uranium in the U^{4+} ionic form migrates to the phosphogypsum owing to four main reasons:

(i) Unreacted rock particles containing U^{4+} become coated with phosphogypsum;
(ii) Some substitution by U^{4+} occurs in the crystal lattice of phosphogypsum;
(iii) Residual amounts of phosphoric acid, containing uranium phosphate, remain with the phosphogypsum after filtration and transport to the stack;
(iv) U^{4+} may adsorb on to the surface of phosphogypsum as UO_2HPO_4.

The residual phosphoric acid remaining with the phosphogypsum may also contain a small amount of uranium in the form of uranyl ions (UO_2^{2+}). Moreover, substitution of Ca^{2+} ions by uranyl ions may occur on the surface of the phosphogypsum crystal lattice [140].

Data on radionuclide activity concentrations in phosphogypsum are given in Appendix VI. The activity concentrations of ^{238}U are mostly below 0.1 Bq/g, with occasional higher values possibly indicative of lower recovery levels of phosphate in the attack tank due to some degree of inefficiency in the process. The activity concentrations of ^{226}Ra and its progeny are generally in the range 0.2–3 Bq/g for material derived from sedimentary phosphate ore. The ^{226}Ra concentrations in phosphogypsum derived from igneous ore are lower, ranging from less than 0.01 to 0.7 Bq/g. The worldwide distribution of ^{226}Ra activity concentrations, estimated by fitting a lognormal curve to the available data, is shown in Fig. 31. The arithmetic mean of the distribution is 1 Bq/g. Activity concentrations vary between stacks and even between different levels in stacks, depending on factors such as age and source rock characteristics.

There is potential for the removal of some of the radionuclides from phosphogypsum while it is still in slurry form. Reduction of the radionuclide content using a cyclone has been attempted on the basis of indications that a higher proportion of the radioactivity is to be found in the fine fraction, although

ED_005285_00000684-00132

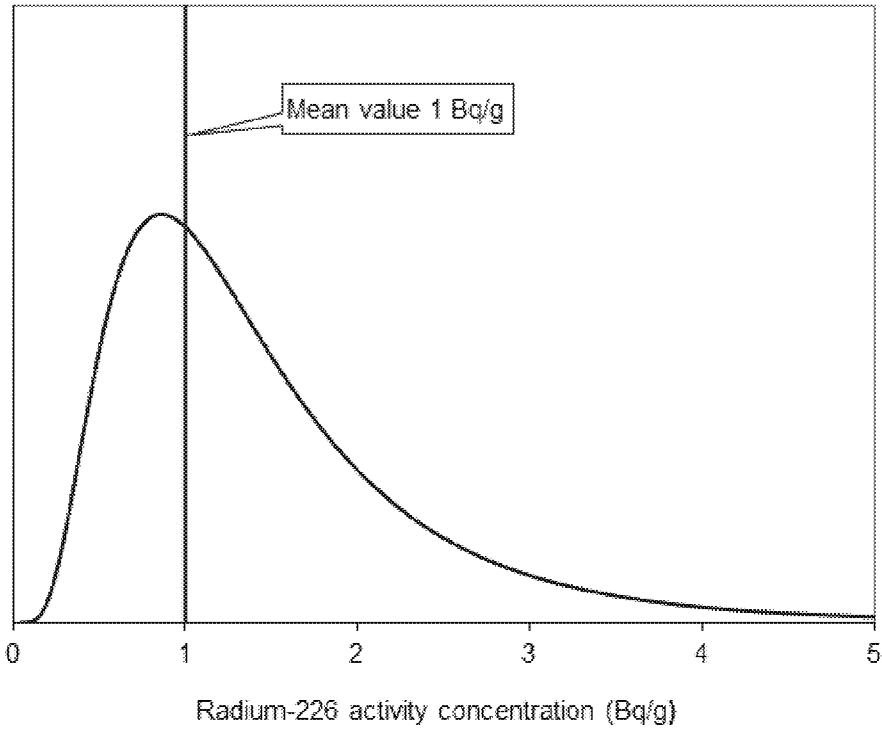

FIG. 31. Estimated worldwide distribution of ^{226}Ra activity concentrations in phosphogypsum.

this is not supported by more recent data [141]. The sulphates of radium and calcium differ in ionic radius, crystalline structure and solubility (calcium sulphate is slightly soluble and radium sulphate is highly insoluble) [142] and thus would not be expected to co-crystallize.

Any large scale radiochemical purification of phosphogypsum is dependent on economic factors. A process known as the Merseberg ammonocarbonation process yields ammonium sulphate, an excellent fertilizer, and calcium carbonate, a useful product for neutralization of acidic water. This process has been used on a commercial scale in China, India and Indonesia. Almost all the radioactivity within the phosphogypsum migrates to the calcium carbonate, leaving the ammonium sulphate fertilizer product lower in radioactivity than most natural materials. However, the process has enjoyed only limited use because of abundant supplies of inexpensive ammonium sulphate from other industries.

ED_005285_00000684-00133

10.4. STORAGE OF PHOSPHOGYPSUM

The amounts of phosphogypsum stored in stacks are vast (approximately 3 billion t worldwide). There are stacks of various sizes in well over 50 countries, of which the largest cover land areas measured in square kilometres. In Florida, USA, for instance, there are some 25 stacks covering a land area of more than 50 km^2 [143], implying an average area of more than 2 km^2 per stack. The management of phosphogypsum stacks requires care because of the large volumes and land areas involved, the potential for emissions of dust and radon gas to the atmosphere and the potential for seepages containing fluorides, heavy metals (such as cadmium) and, to a lesser extent, radionuclides. The management approach for phosphogypsum stacks is no different in principle from that for engineered structures containing other types of NORM in bulk amounts, such as residues (tailings and waste rock) from the mining of radioactive ores. This management approach is described in Ref. [5]. The following basic measures help to mitigate or prevent any negative impact:

(a) The provision of perimeter systems to contain possible leaks or spills;
(b) The use of suitable liners to prevent contamination of groundwater [144];
(c) The provision of a well-maintained water cover to reduce airborne emissions of dust and radon gas;
(d) The provision of a system of dust suppression in the case where it is not feasible to provide a water cover, either by keeping the material wet or by planting grass or other light vegetation (although the establishment of vegetation may increase the rate of radon emission).

There are two methods of stacking: wet stacking and dry stacking. The wet stacking method is the more common of the two. It is used by most of the plants that produce dihydrate phosphogypsum and by several plants producing hemihydrate phosphogypsum [145, 146]. In the latter case, the free water associated with the use of the wet stacking method causes the hemihydrate material to convert to the dihydrate form (see Section 5.1.1.1). Although the conversion is not complete by the time the slurry reaches the stack, the management approach, in terms of the methods and equipment used, is the same as that for stacking phosphogypsum from dihydrate plants. Where water is available at a reasonable cost, wet stacking is easier, more reliable and less costly to carry out than dry stacking. It has a further economic benefit in that P_2O_5 recovery is improved if the water is recycled back to the process. Unlike dry stacking, wet stacking does not involve 'construction around the clock' and can be carried out with significantly less equipment and fewer personnel. Airborne dust generation, which can be a problem with dry stacking, is generally not a

ED_005285_00000684-00134

problem with wet stacking because most of the surface area remains wet. Perimeter and internal partition dykes cover relatively limited and defined areas, and construction traffic is restricted to specific maintenance and access roads that are relatively easy to keep damp.

10.4.1. Wet stacking

In wet stacking operations (see Fig. 29), the phosphogypsum is mixed with water as it leaves the filtration system and is pumped as a slurry through a pipeline to a holding area within the stack where the solids settle out.

10.4.1.1. Water circuit

The water associated with wet stacking is managed either as a closed circuit (recirculating) system or an open circuit (once through) system:

(a) In closed circuit systems, process water, also known as pond water, is used for transporting the phosphogypsum to the stack at a typical solids content of 20–30%. The water is clarified by allowing the solids to settle and is then decanted and pumped back to the plant, where it is reused for slurrying the phosphogypsum or for other process applications. The recirculated process water becomes more acidic over time, usually reaching an equilibrium pH somewhere within the range 1–2, depending on process and climatic variables. The soluble P_2O_5 content of the acidic process water typically reaches 10 000–25 000 mg/L, but can be as high as 35 000 mg/L. Recirculated water can be used to wash the filters and re-slurry the gypsum cake to recover P_2O_5. Washing with high P_2O_5 content water improves P_2O_5 recovery, which is one of the significant advantages of wet stacking. In a wet stack, the operator recovers soluble P_2O_5 from water entrained in the gypsum cake, with some additional P_2O_5 recovery from unreacted rock over time, as well as P_2O_5 contained in plant spills diverted to the pond. It is not uncommon to improve P_2O_5 recovery in a wet stack by as much as 3%. In wet climates, excess water due to rain may sometimes give rise to the need for additional treatment before discharging to a receiving water body.

(b) In open circuit systems, the water used for generating the slurry, rather than being recirculated, is discharged as an effluent containing phosphates, fluorides and suspended solids. At coastal locations, the water may be extracted from the sea and discharged back to the sea after clarification. Seawater slurries are usually very dilute (about 5% solids by weight) and the pH of the water being discharged is greater than 2.

ED_005285_00000684-00135

In the light of experience gained from the treatment of the highly acidic process water associated with closed circuit systems [147] and from dealing with spills in locations such as Florida and Louisiana, USA [33], it has been argued that the use of fresh water rather than recirculated water for creating the slurry would bring about significant environmental protection benefits, especially if the phosphogypsum is first washed with fresh water. Open circuit operation may also be favoured for other reasons; in arid climates, closed circuit operation may not be feasible because of evaporation from the pond, while in other situations, open circuit operation may be the more attractive option because of the existence of a large, nearby body of water, such as the sea. Nevertheless, closed circuit systems are generally preferred to open circuit systems because they do not generate liquid effluent.

Some phosphogypsum stacks have been converted from seawater (open circuit) systems to process water (closed circuit) systems. After conversion, the water returned to the plant from the stack is, initially at least, highly corrosive because of contamination with chlorides leached from the previously deposited phosphogypsum. Special measures would have been needed to reduce such contamination. The use of seawater at production facilities in Greece, Mexico, Spain and Tunisia has progressively stopped, although in most cases not as a result of decisions to convert to closed circuit systems but rather because of plant closure for financial reasons unrelated to the choice of water management system. In some cases, the change has been driven by the need to conform with environmental regulations, such as in Mexico and Tunisia, while in others the cost of changing process to achieve compliance has been so high that the production facility has simply closed altogether. In Spain, a change was made in the late 1990s from partial (20%) discharge to a closed circuit driven by the desire to eliminate completely any negative impact from process waters used for transporting phosphogypsum to the stacks.

10.4.1.2. Construction and operation of stacks

The stack perimeter is established by constructing 'starter dykes'. Control of the slurry within the stack during operation is achieved using a technique known as elevated rim ditching, as illustrated in Fig. 32, and a system of pipes and valves, known as spigots, that direct the phosphogypsum slurry to various places on the top of the stack (see Fig. 33). The construction of starter dykes and rim ditches is usually carried out using earthmoving equipment, as shown in Figs 32 and 34. The use of wet gypsum for construction work avoids the generation of airborne dust. The emission of dust from maintenance and access roads as a result of their use by construction traffic is controlled by keeping the roads damp.

ED_005285_00000684-00136

FIG. 32. Elevated rim ditching.

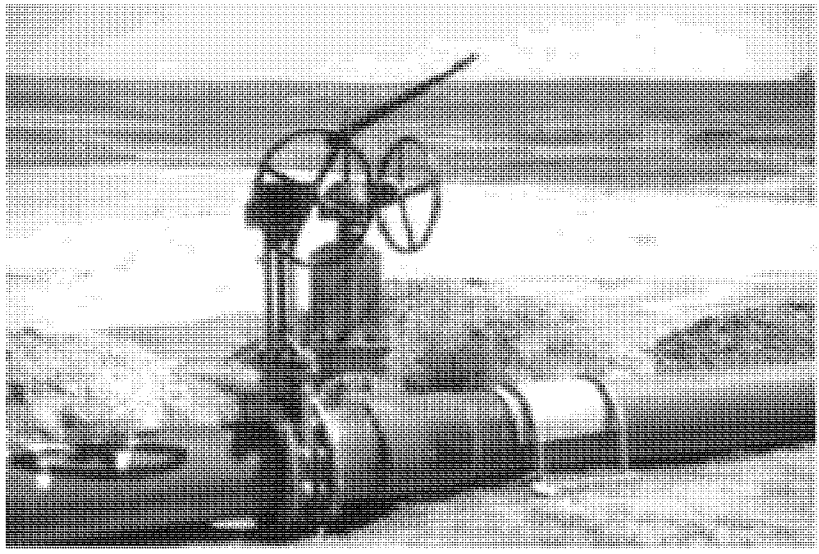

FIG. 33. Pipes and valves (spigots) for control of slurry on a stack.

ED_005285_00000684-00137

FIG. 34. Stack construction work using wet phosphogypsum.

For safety reasons, rim ditches are constructed in accordance with specific geometric requirements and construction techniques, ensuring that all the rain that falls on the slurry ponds during operation is contained. A specified freeboard needs to be maintained to prevent the rim dams from being breeched by wave action in windy conditions. In Florida, USA, the freeboard requirement had to be increased following a succession of severe rainfall events which led to the near overflow of a stack at Piney Point in 2002 (see Fig. 35) [148].

A ditch or channel usually surrounds the stack to retain any lateral seepage at the toe of the stack and rainfall runoff contaminated by contact with non-vegetated side slopes. This ditch or channel may also serve as a process water cooling pond. A process water management system at a stack in Spain is shown in Fig. 36. In wet climates, excess water in the ditch or channel may be returned to the chemical plant as process make-up water or pumped to the top of the stack for storage, from where it is eventually consumed as process water or discharged to a receiving water body after appropriate treatment. The treatment of excess water usually consists of two-stage lime neutralization and clarification. The treated water contains high concentrations of dissolved solids, sulphate and sometimes ammonia. Process water that has not been in contact with phosphogypsum can,

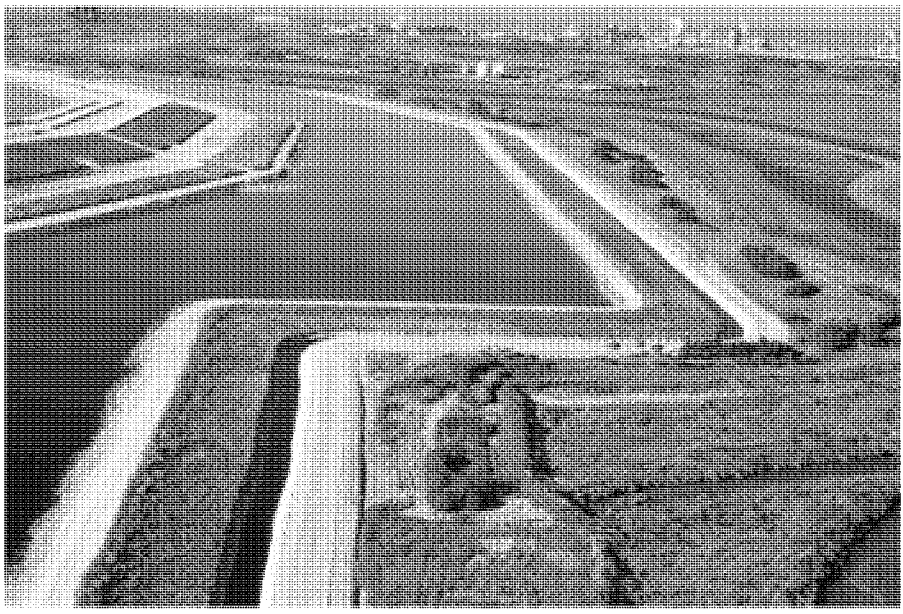

FIG. 37. Vegetation of side slopes at a phosphogypsum stack at Huelva, Spain.

alternatively, be treated using reverse osmosis. The quantity of excess process water needing to be treated and discharged can usually be reduced, and possibly even eliminated, by having adequate surge capacity and by following appropriate procedures for the operation of the phosphogypsum stack and the chemical plant. For example, by conditioning and vegetating the bare stack slopes, as illustrated in Fig. 37, rainfall can, over time, be prevented from coming into contact with the phosphogypsum, thus avoiding contamination and enabling side slope runoff to be segregated and discharged without treatment.

10.4.1.3. Control of groundwater contamination

Contamination of groundwater by seepage from phosphogypsum stacks is an obvious environmental concern and it is common for new stacks to be constructed with an impervious bottom liner over a drain field that can be monitored for possible liner leakage. A typical stack liner is shown in Fig. 38. Measures for containing seepage from existing stacks can be implemented retrospectively. In some situations, a vertical hydraulic barrier comprising a soil–bentonite cut-off wall, or 'slurry wall', is built around the perimeter of the site, along with pressure relief wells. In other situations, a high density polyethylene (HDPE) geomembrane is installed on top of the stack, in order to serve as a bottom liner for subsequent deposits of wet phosphogypsum.

ED_005285_00000684-00140

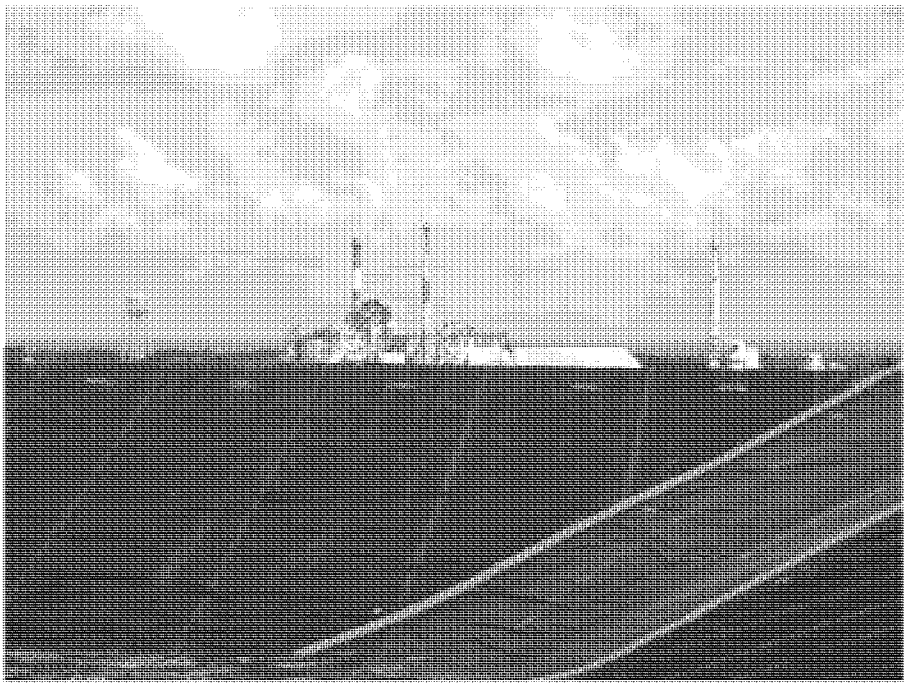

FIG. 38. Liner for a phosphogypsum stack.

In some regulatory jurisdictions, the use of a liner is a legal requirement. In Florida, USA, for instance, unless it had been demonstrated that groundwater impacts would be contained indefinitely within the property line or within a designated zone of discharge, all existing stacks and associated process water ponds had to undergo engineering modifications to contain any seepage or be closed and replaced by new lined facilities. Furthermore, all new stacks now have to include an impervious bottom composite liner system, consisting of an HDPE geomembrane 1.5 mm thick in combination with either a compacted clay layer beneath it or a compacted gypsum layer above it [149]. Nevertheless, it would appear that, depending on the conditions at the site, a liner is not always essential for controlling seepage. After many years of operation of stacks without liners, such as those at Huelva, Spain, it has been demonstrated that in many cases the substrate underlying the stack has remained impermeable and this, together with the inherent properties of phosphogypsum to form a largely impermeable compacted base, has resulted in there being little difference between lined and unlined stacks in terms of their potential for groundwater contamination. In Florida, USA, an evaluation of groundwater impacts from unlined stacks showed that heavy metals and radionuclides in the seepage water are attenuated by the

ED_005285_00000684-00141

FIG. 39. A major sinkhole in an active phosphogypsum stack [33].

fine grained soils and calcareous strata upon which most of these structures are built [83, 150–152].

10.4.1.4. Control of fluoride emissions to the atmosphere

Fluorides, mainly in the form of hydrogen fluoride, are emitted from phosphogypsum pond water surfaces. These emissions can be reduced significantly if fluosilicic acid is extracted during the phosphoric acid production process.

10.4.1.5. Structural failures of stacks

Among the more spectacular problems associated with wet stacking is the occurrence of massive sinkholes, of which there have been four or five in Florida, USA, alone. Even a lined stack of modern design cannot cope with sinkholes of the size shown in Figs 39 and 40. Wet stacking of phosphogypsum is usually governed by regulations that typically require an extensive investigation of the subterranean conditions to determine the potential for sinkholes.

There have also been major spillages of acidic water due to structural failures of pond retention systems. While such failures are relatively rare, they

ED_005285_00000684-00142

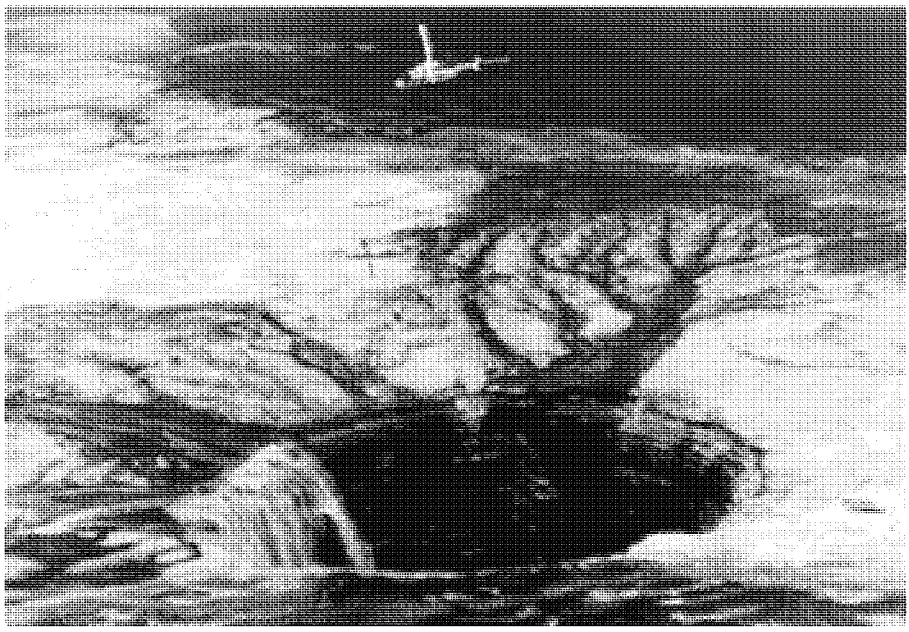

FIG. 40. A sinkhole in a phosphogypsum stack (helicopter gives a sense of scale) [33].

may have a significant impact on surface water bodies, more as a result of the acidic nature of the water than as a result of its radionuclide content [33].

Examples of events occurring in the USA involving failure or near failure are the following:

(a) In 1997, tens of thousands of cubic metres of acidic water escaped from a stack in Florida and polluted a nearby river.[21]

(b) In 2002, at a facility in Florida, a combination of extreme weather events and neglect caused by the bankruptcy of the owning company led to the near overflow of a stack, which would have resulted in total stack failure in a highly environmentally sensitive area. The only remedy was the emergency discharge of neutralized water by barge far out to sea, which was undertaken at very great cost.

[21] State and local agencies are providing over $1 million to restore, preserve and improve the estuarine habitats in the affected Alafia River and adjacent areas of Tampa Bay into which the river flows. The Alafia River Spill/Mulberry Phosphate Restoration Council that was formed to aid the river's environmental recovery announced that it would fund estuarine restoration projects to improve the habitat along the Alafia River (see, for example, http://www.floridadep.com/southwest/news/101003.htm).

ED_005285_00000684-00143

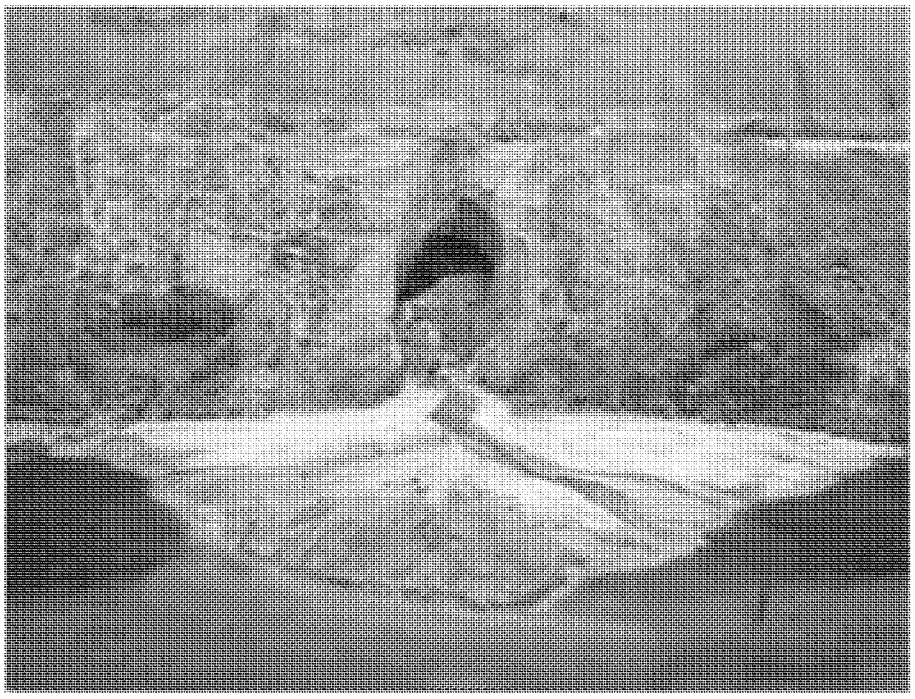

FIG. 41. Side slope failure at Piney Point, Florida, USA, in 2003 (courtesy: Florida Department of Environmental Protection).

(c) In 2004, 227 000 m^3 of acidic water escaped from a stack, also in Florida, into a neighbouring creek. The apparent cause was damage done to the pond wall by waves driven by the force of a hurricane that hit the area.

(d) In 2004, there was a spill from a stack in Florida, which fortunately did not extend beyond the property.

(e) In 2005, about 65 000 m^3 of acidic water escaped from a stack in Mississippi into surrounding marshland. The company argued that excessive rainfall was the cause, while state officials believed it was an error on the part of the company in trying to fill the process water pond too rapidly.

Other failures associated with stacks of modern design include side slope failure (see Fig. 41) and liner breaches, which by comparison are relatively inexpensive to deal with.

ED_005285_00000684-00144

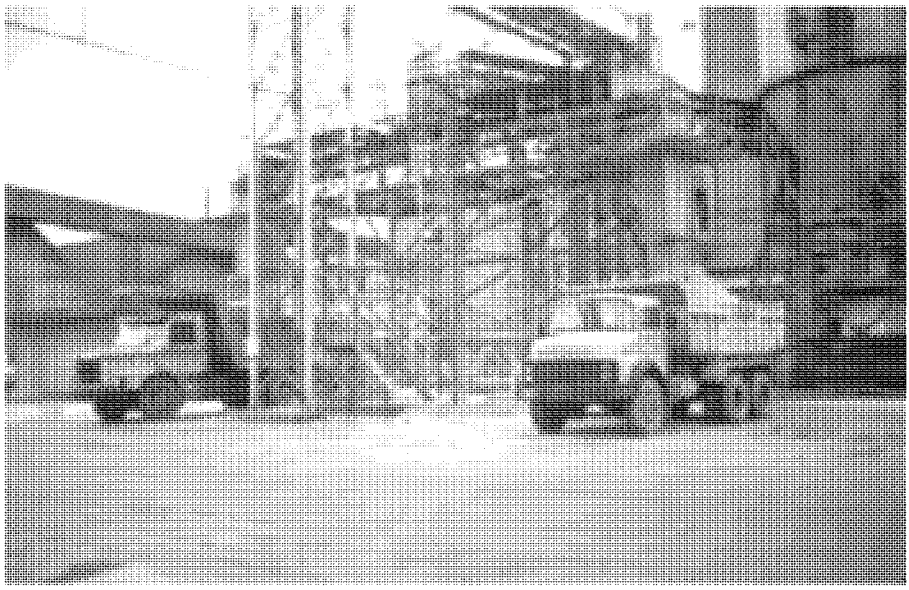

FIG. 42. Loading of phosphogypsum into trucks [146].

10.4.2. Dry stacking

In dry stacking operations, phosphogypsum leaving the filtration system is transported to the stack by belt conveyor or truck, without the addition of water (see Fig. 42). Upon reaching the stack, the material is deposited and spread using equipment such as mechanical stackers, movable belt conveyors and bulldozers (see Fig. 43). Dry stacking, although less widely practised than wet stacking, has been carried out in various parts of the world, including Brazil, Jordan, Senegal, Tunisia and several countries of the former Soviet Union. In Jordan, dry stacking is practised at Aqaba for dihydrate phosphogypsum and at Eshidiya for hemihydrate phosphogypsum.

The moisture content of the phosphogypsum emerging from the filtration system is sufficient to prevent the emission of airborne dust from the material while it is being transported on belt conveyors or in trucks. However, the spillage of phosphogypsum from conveyor belts and trucks, as well as at any transfer points, is a potential source of airborne dust if the spilt material is allowed to dry before being removed. For this reason, the conveyor may need to be enclosed. The use of a high pressure water spray on the underside of the conveyor at the discharge end removes any phosphogypsum adhering to the belt. The wash water from the spray system is collected and consumed as process water or appropriately treated and discharged.

ED_005285_00000684-00145

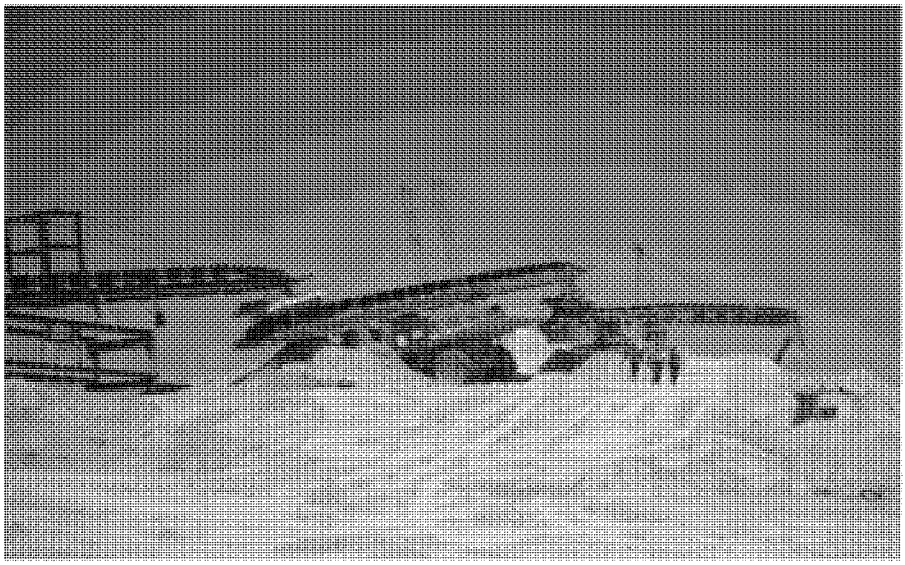

FIG. 43. Spreading of phosphogypsum in a dry stacking operation.

When dry stacking operations are carried out in areas with unusually high rainfall, such as at Santos, Brazil, where the average annual rainfall is 3 m, the stack surfaces remain permanently damp and no significant emissions of airborne dust occur. In less extreme climatic conditions, the stack surfaces dry out between periods of rainfall. A thin, fragile crust forms on the stack surface, which can help to minimize the emission of airborne dust as long as it remains undisturbed by the wind and by the construction equipment used for placing and spreading the phosphogypsum. The emission of airborne dust as a result of the disturbance of this crust creates not only a dust problem, but also leads to the emission of fluorides and radon that emanate from the surfaces of the dust particles. Dust emission from dry stacking operations (and the resulting fluoride and radon emissions) is controlled by limiting the extent of the active placement area and haul roads and by spraying the surfaces with water to keep them damp.

Rainfall runoff from the stack is collected and returned to the chemical process or used to suppress the emission of airborne dust from maintenance and access roads. Dry stacking does not eliminate the possibility of acidic seepage from the base of the stack and from the toe of the side slope. Even in desert climates, a bottom liner may need to be incorporated to prevent groundwater contamination because vertical cracks tend to form within the stack as a result of differential settlement and/or side slope instability. These cracks create paths for the entry of water deep into the stack during relatively rare heavy rainfall events. Filling of these cracks with phosphogypsum minimizes the entry of rainwater and

ED_005285_00000684-00146

also helps prevent possible slope instability caused by hydraulic pressures generated within the water filled cracks.

10.4.3. Environmental impacts

As explained in Sections 10.4.1 and 10.4.2, measures are taken during the construction and operation of phosphogypsum stacks to ensure that the runoff of contaminated rainwater is contained within the stack perimeter, that effluent water is treated before discharge and that seepage into the groundwater and emission of dust to the atmosphere are controlled. These measures are designed to keep the environmental impacts of phosphogypsum stacks within acceptable bounds. Contamination of groundwater near phosphogypsum stacks is, in any case, restricted by the limited solubility of radium and other radioactive species in sulphate form [81]. A detailed investigation was carried out on the processes responsible for controlling the interaction and release of radionuclides from phosphogypsum from a phosphogypsum stack at Piney Point Phosphates in Florida [81]. On the basis of measurements of activity concentrations in groundwater collected from several monitoring wells around the stack, it was concluded that various removal mechanisms, including adsorption within the stack, precipitation within the soil horizons just below the stack and interception of stack fluids by drainage ditches, prevent large scale migration of radionuclides to the underlying aquifer. However, some of the laboratory studies on the leaching characteristics of ^{226}Ra from phosphogypsum showed a dependence on various conditions such as solution:solid ratios, contact times and acidity on dissolution rates [153, 154]. Forced leaching experiments indicated that uranium dissolution largely depends on the presence of phosphoric acid traces in phosphogypsum. Studies indicated that the leaching of radium may be slow in field conditions near phophogypsum stacks, especially when the phosphogypsum is previously washed and stored.

An investigation of the impact of phosphogypsum stacks on surface water systems was carried out in the Cubatão region of southern Brazil [155]. Sediments were sampled from a river receiving effluent discharged from nearby phosphogypsum stacks. Near the point of discharge, the concentrations of barium, zirconium and thorium in the sediment were found to be elevated above local background levels. The samples also showed the presence of rare earth elements at elevated concentrations and with a higher degree of fractionation in comparison with the concentration ratios of individual rare earth elements in phosphate rock. The mean concentrations of cerium in surface and core sediments were 151 and 387 ppm, respectively, which may not be desirable in surface water streams. These results were consistent with the contaminants having originated from the phosphogypsum, the characteristics of which reflected

ED_005285_00000684-00147

the composition of the Catalão igneous phosphate ore, with some modification as a result of the phosphoric acid production process. The sediment contamination levels were found to decrease rapidly in the downstream direction, indicating that the influence of the phosphogypsum stacks was confined to a small area.

The emission of fluorides from ponds in wet stacking operations has been measured. The rate of emission was found to be in the range 0.01–0.10 $kg \cdot ha^{-1} \cdot d^{-1}$. Elevated levels of fluorides have been found in vegetation growing very close to a phosphogypsum stack [156]. The repeated ingestion of such vegetation by cattle over periods of years may cause fluorine toxicosis, also known as fluorosis or brittle bone syndrome.

In some countries, the recent spread of residential and commercial property development has resulted in members of the public living and working ever closer to phosphogypsum stacks. Some older stacks have now become surrounded by developed metropolitan areas. In Huelva, Spain, for instance, residential apartments are being built less than 300 m from an operating stack. Nevertheless, measurements have indicated that exposure levels diminish very rapidly with distance from the stack [94].

Measurements of radon concentrations in the air around phosphogypsum stacks have been reported from a few countries. The average radon concentration above a phosphogypsum stack in Huelva was recorded as 13.1 Bq/m^3 over a measurement period of six months and comparable with the natural background levels measured in the adjacent residential areas [157]. Measurements were also reported from a phosphogypsum stack in India [74]. The ^{222}Rn concentrations were 9–45 Bq/m^3 in the indoor environment, close to the stack, and were also comparable with the background concentrations in the local environment.

The radon emanation factor for phosphogypsum is typically about 0.2 [158]. Measurements of the emission of radon have been made on the surfaces of several phosphogypsum stacks in central Florida, USA [150, 151], and on one stack in south-western Spain [159]. The results are shown in Table 33. The Spanish study found that radon exhalation rates above the surface of a stack were an order of magnitude higher than those found in the reference site (agricultural soil), with no significant enhancement in radon exhalation rates during tillage or digging of the stack surface. However, since the stack surface is open to the atmosphere, no significant buildup of radon above the stack was observed.

Investigations have also been carried out at Huelva, Spain, on the aerosol activity concentrations above phosphogypsum stacks after preliminary restoration work [160]. The ^{238}U, ^{226}Ra and ^{210}Pb concentrations in airborne dust were 0.016, 0.01 and 0.6 mBq/m^3, respectively, and were comparable to background levels. The corresponding incremental inhalation dose received by maintenance workers was estimated to be 0.7 μSv/a. The formation of a hard crust on the surface of inactive stacks also prevents resuspension of particles and

ED_005285_00000684-00148

TABLE 33. RADON EMISSION FROM PHOSPHOGYPSUM STACKS

Location	Mean Ra-226 concentration in phosphogypsum (Bq/g)	Mean radon flux ($Bq \cdot m^{-2} \cdot s^{-1}$)	Radon flux per unit Ra-226 concentration ($Bq \cdot m^{-2} \cdot s^{-1}$ per Bq/g)
Central Florida, USA [150, 151]:

Intermittently ponded areas	1	0.075	0.075
South-western Spain [159]:			
Undisturbed surface	0.73	0.01–0.16	0.014–0.22
Surface disturbed by tilling	0.73	0.04–0.3	0.055–0.41
Agricultural soil (for comparison)	0.035	0.003–0.011	0.086–0.31

[a] The individual mean radon fluxes from the stack, side slopes and access roads were similar.

these results indicate that dust inhalation on a restored phosphogypsum stack does not result in significant exposure.

Several studies have been performed to determine the dose received by workers engaged in phosphogypsum stacking operations. The gamma doses received by maintenance workers on stacks in Spain were 0.25–0.35 mSv/a, assuming 2000 h of occupancy, which is quite conservative [157]. In this context, it is worth mentioning that workers perform a variable but significant fraction of their work inside trucks and other machinery which act as shielding against gamma radiation, implying even lower doses in practice.

10.5. USE OF PHOSPHOGYPSUM

10.5.1. Agriculture

Phosphogypsum is used in agriculture throughout the world [33], for example in Australia, Bangladesh, Brazil, Egypt, India, Kazakhstan [136], Pakistan, Spain [161], the Syrian Arab Republic and the USA [162]. In Brazil, 40% of all phosphogypsum produced is used in agricultural applications. In California, USA, a stack of phosphogypsum originating from phosphate rock from Idaho and Wyoming was utilized completely for agricultural purposes, prior to such use being restricted by regulations in 1989. A very small quantity of phosphogypsum with a low radium content produced in Florida, USA (representing only 0.03% of total

ED_005285_00000684-00149

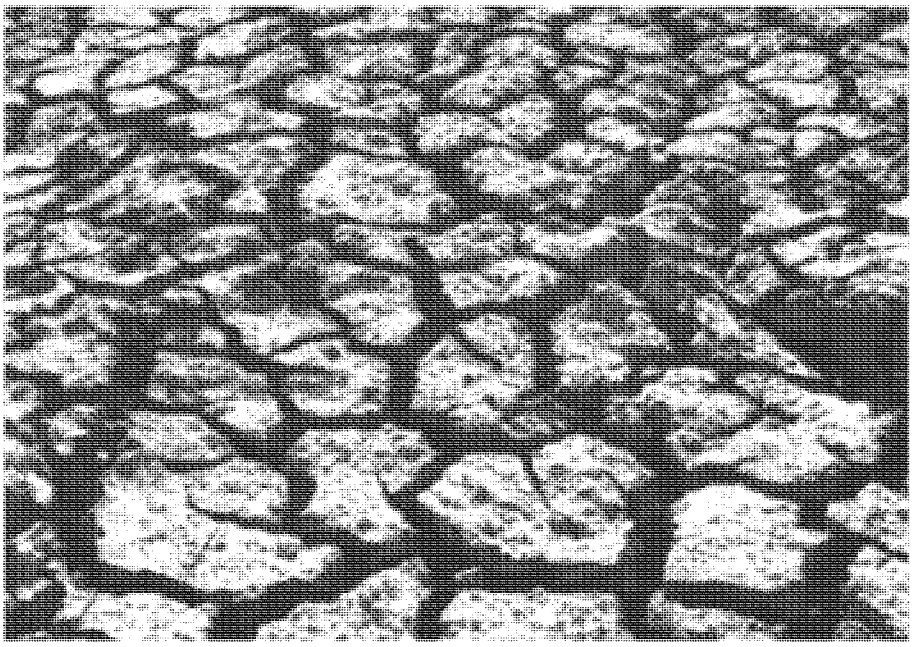

FIG. 44. Soil near Huelva, Spain, prior to remediation with phosphogypsum (courtesy: University of Seville, Spain).

Florida production), continues to be used as a soil amendment in peanut farming. In the European Union, phosphogypsum is permitted for use as a soil amendment under the category 'calcium sulphate' [163, 164]. Phosphogypsum contributes to agricultural production in four principal ways:

(i) Reclamation of land such as estuarine marsh in order to render it agriculturally productive;
(ii) Remediation of saline and sodic soils (see Fig. 44);
(iii) Amendment of soil to prevent crusting and to enhance water retention;
(iv) Fertilization of soil for growing crops and pasture.

Phosphogypsum usually does not need to be tilled into the soil. Freshly generated phosphogypsum is unweathered and moist, and in this state it can be applied directly to the surface of the soil using conventional methods of distribution (see Fig. 45).

A large area of land near Huelva, Spain, has been progressively reclaimed by the application of phosphogypsum and returned to productive agricultural use. An aerial view of the reclaimed land is shown in Fig. 46. This site is particularly

ED_005285_00000684-00150

FIG. 45. Direct application of phosphogypsum to soil (courtesy: University of Seville, Spain).

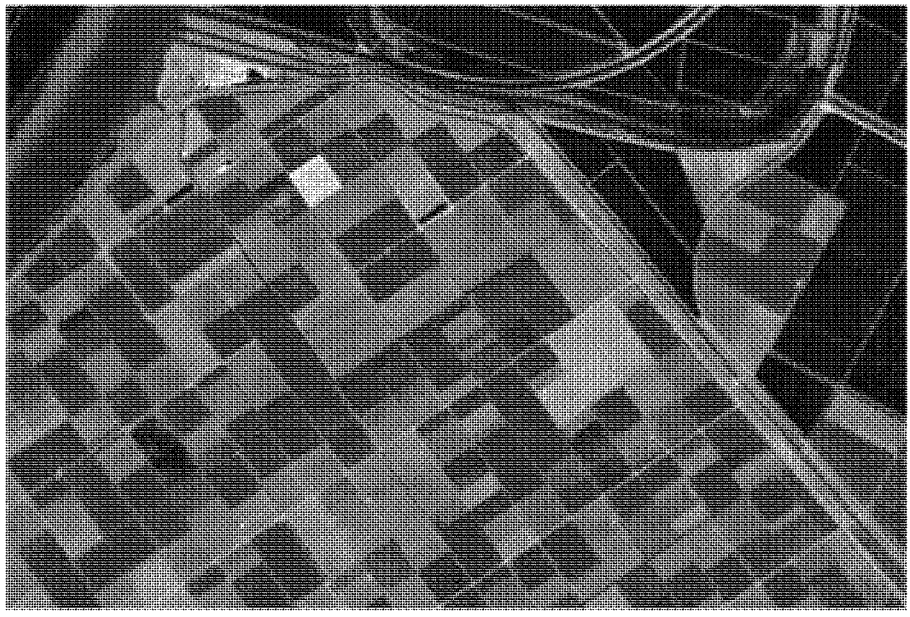

FIG. 46. Land reclaimed by the use of phosphogypsum (courtesy: University of Seville, Spain).

ED_005285_00000684-00151

significant in terms of risk assessment since it is the only documented area in the world which can be used to study the impact of 40 years of continuous use of phosphogypsum on soils, a practice that still continues at this locality.

The benefits of applying phosphogypsum to saline and sodic soils are described in Refs [136, 161, 162] and include:

(a) Reduced sodium and aluminium toxicity of the soil;
(b) Increased calcium and sulphur dissolved from the phosphogypsum;
(c) Increased ammonia retention by the soil;
(d) Increased water retention of the soil through better conditioning;
(e) Greater water efficiency.

The use of phosphogypsum as a fertilizer, typically at application rates of 100–600 kg/ha, has been found to increase significantly the production rates of the following crops [33]:

Alfalfa	Carrots	Lemons	Peaches	Sugar beet
Apples	Citrus	Lentil	Peanuts	Sugar cane
Avocado	Coffee	Limes	Pepper	Sweet sorghum
Bahia grass	Corn	Lucerne	Pineapple	Tea
Barley	Cotton	Maize	Rapeseed	Tobacco
Beans	Cover crops	Mustard	Rice	Tomato
Beets	Forage	Niger	Rye grass	Turnip
Bermuda grass	Frasier fir	Onion	Sorghum	Upland rice
Black gram	Groundnuts	Oranges	Soya beans	Vegetables
Cabbage	Guinea grass	Pasture grass	Squash	Wheat

Phosphogypsum is often used in its unmodified state. Depending on the specific crop application, however, it may be necessary to remove the acidic water (and even some of the other impurities) contained within it. For example, phosphogypsum 'harvested' for agricultural use from the inactive portion of a stack in northern Florida, USA, is first exposed to rainwater for about a year. When the rainwater permeates the phosphogypsum, the acidic process water contained in the phosphogypsum is displaced, causing the pH of the harvested phosphogypsum to increase to a value greater than 5. In general, any removal of impurities has to be kept to a minimum to avoid making the use of phosphogypsum uneconomic compared with the use of relatively inexpensive natural gypsum.

ED_005285_00000684-00152

The use of phosphogypsum as a soil amendment has been studied extensively to determine the extent to which the introduction of additional heavy metals and radionuclides through the application of the phosphogypsum could lead to possible human health effects via the following pathways:

(a) Uptake of radioactivity and heavy metals from the amended soil by edible crops;
(b) Inhalation of radionuclides in airborne dust during the application of the phosphogypsum;
(c) External exposure rates due to the amended soil;
(d) Groundwater contamination;
(e) Radon emission from the amended soil.

In an evaluation of the application of phosphogypsum as a soil amendment and fertilizer [165], phosphogypsum with a ^{226}Ra activity concentration of about 1 Bq/g was assumed to have been applied to the soil every second year for 100 years after an initial application of twice the biennial application rate. Six scenarios were considered, involving various rates of phosphogypsum application in the range 1.66–10 t/ha and tillage depths of 22–46 cm. After the 100 year period, ^{226}Ra concentrations in the soil were calculated to be 0.03–0.12 Bq/g.

An investigation was carried out to determine the effect of phosphogypsum, when used as a calcium fertilizer for the production of crops such as cotton, on the resulting levels and behaviour of radionuclides [166]. Phosphogypsum with a ^{226}Ra activity concentration of 0.51 Bq/g was applied at rates of 13 and 26 t/ha in conjunction with manure at a rate of 30 t/ha. The concentrations of ^{226}Ra in the water draining from the fertilized areas were similar to those reported for non-treated areas (2.6–7.2 mBq/L).[22] The results revealed that the activity concentrations of ^{226}Ra in the crops were not affected by the phosphogypsum treatment and that there was no accumulation of radioactivity in the soil. Similar studies to investigate the buildup of radioactivity in soil or uptake by crops show no significant uptake in most cases [167, 168]. In a study carried out in five land parcels of the central Florida phosphate district, approximately 70 indidividual

[22] While the ^{226}Ra concentrations in the drainage water were not found to be elevated, the concentration of ^{238}U was found to be 200 mBq/L; an order of magnitude higher than normal. However, the ^{234}U:^{238}U isotopic ratio in the uranium-enriched drainage water was 1.16, as opposed to a ratio of 1 in the phosphogypsum and other phosphorus fertilizers used, from which it was concluded that most of the additional uranium in the drainage water did not originate from the phosphogypsum but was thought to originate instead from the uranium naturally present in the soil (at a ^{238}U activity concentration of 0.025 Bq/g) that had become desorbed.

ED_005285_00000684-00153

FIG. 47. Greenhouse studies involving various crops (courtesy: University of Seville, Spain) [170].

food samples were collected and analysed for ^{226}Ra, ^{210}Pb and ^{210}Po [62, 63]. Concentrations of ^{226}Ra and ^{210}Pb in food grown on mined phosphate lands were statistically higher than the concentrations of these nuclides in foods from unmined lands. However, an upper estimate of the likely incremental increase in annual ingestion dose was only 0.027 mSv. A radiological impact assessment of the application of phosphogypsum in agriculture was reported from Greece [169]. The concentration of ^{226}Ra in rice and other agricultural products produced from soil tilled with phosphogypsum ranged from 0.0004 to 0.002 Bq/g and the estimated ingestion dose was 0.86 μSv/a.

A completely randomized greenhouse experiment was carried out in Spain growing tomato (*Lycopersicum esculentum* Mill L.) using a reclaimed marsh soil amended with various rates of phosphogypsum up to 20 t/ha to investigate the transfer of ^{238}U, ^{226}Ra, ^{210}Po, Pb and Cd to the crop [170]. The experimental set-up is shown in Fig. 47. The concentrations of ^{238}U and ^{226}Ra in the crops were below the detection limit in all cases and the concentration of ^{210}Po was 0.0004–0.0007 Bq/g on a dry weight basis. The results also showed that the

ED_005285_00000684-00154

application of phosphogypsum as a calcium amendment for agricultural purposes could lead to some uptake of cadmium in the plants.

In the Cerrado region of Brazil, where significant amounts of phosphogypsum are used for agricultural purposes, a field study explored the impact on two typical soils of the region, one clayey and the other sandy. These analyses included an evaluation of the mineralogical composition, the organic matter content and the concentrations of P, K, Ca, Mg and Al. The concentrations of radionuclides and metals in the phosphogypsum and soil samples were also measured. The organic matter content of the soil samples was low and the potential acidity high. The mean ^{226}Ra activity concentration in the phosphogypsum samples was 0.252 Bq/g. In addition, this study verified that the concentrations of radionuclides and metals in the phosphogypsum were lower than the background concentration in the clayey oxisol soils of Sete Lagoas, Minas Gerais, Brazil. These results indicated that the application of phosphogypsum as a soil amendment in agriculture would not have a significant impact on the environment [171].

A three year field study in Florida, USA, involving the application of phosphogypsum at relatively low rates (up to 4 t/ha), showed no statistically significant increases in radionuclide concentrations in soils and groundwater or in the levels of airborne radon and gamma radiation measured 1 m above the plots [172]. A subsequent study, which has become a benchmark because of its comprehensive methodology and scope [173], developed data to assist in the assessment of the environmental impacts of the application of phosphogypsum at higher rates (up to 20 t/ha) to an established bahia grass pasture, primarily in terms of the radionuclides in phosphogypsum and secondarily in terms of the heavy metal impurities. The results can be summarized as follows:

(a) Exposure from the inhalation of radon progeny was determined from measurements of the ^{226}Ra activity concentration in the soil, the radon flux from the soil and the radon concentrations in the air. For the application of phosphogypsum at a rate of 0.4 t/ha over a 100 year period, the incremental radon flux from the amended soil was projected to be about 40% of the mean value for undisturbed land (with no phosphate mineralization) in the region. For a house constructed on the amended soil, the phosphogypsum in the soil was estimated to increase the indoor radon concentration by about 1–10 Bq/m^3 (representing, for a typical house, an increase of about 2–20%). For a cumulative treatment of up to 40 t/ha, the phosphogypsum was predicted to contribute less than 3.7 Bq/m^3 to the radon concentration over the field.

(b) Exposure to external gamma radiation was determined from dose rate measurements made following a single treatment of phosphosgypsum of up

ED_005285_00000684-00155

to 40 t/ha. After the first year, no gamma exposure attributable to the phosphogypsum could be detected. It was concluded that the radionuclides from the phosphogypsum had penetrated the soil or had been removed by weathering or harvesting. The incremental annual effective dose received by an individual remaining permanently on the treated land was projected to be 0.028 mSv after 100 years.

(c) Exposure from the ingestion of radionuclides in water and food was determined from measurements of the activity concentrations of ^{226}Ra, ^{210}Pb and ^{210}Po in samples of soil, water and forage. The results suggested that the radionuclides contained in the phosphogypsum had limited mobility in surface water and groundwater during the first two years after application to the soil. However, it is possible that they may have been gradually mobilized, appearing in the groundwater at a later date. The activity concentrations of ^{226}Ra in shallow groundwater after 100 years of phosphogypsum use were projected to be about 0.1 Bq/L. Levels of ^{210}Pb were projected to be similar to the baseline levels in runoff and shallow groundwater (<0.04 Bq/L). Doses to humans from the ingestion of animal products that had been contaminated with radionuclides taken up by forage appeared to be within the range of variation in a normal diet.

10.5.2. Construction of buildings

Phosphogypsum has been used as a raw material for cement [174, 175] and as a source of plasterboard. Other construction uses include the production of bricks [176], blocks [177], tiles, artificial stone and even boats [178]. Countries using phosphogypsum for building purposes, usually with certain restrictions, include Belgium, Brazil and India. Phosphogypsum is viewed as a potential building material in South Africa, where the construction of low cost housing is being encouraged. Almost all the uses of phosphogypsum for building products require the phosphogypsum to be well washed to remove the acidity from its residual water content and in some cases further processed to remove residual phosphate.

Recent developments in the phosphate industry in countries with rapidly expanding economies, such as China, have led to a major increase in the production of phosphogypsum, which in turn has stimulated interest in its use, including its use in construction applications [179–182]. As a result, the relevant authorities have taken a greater interest in establishing the necessary conditions for the safe use of phosphogypsum [183, 184]. Exposure to building materials incorporating phosphogypsum has been comprehensively and continuously studied [185, 186]. Exposure levels have been found to depend strongly on exactly how the phosphogypsum is used — exposure from phosphogypsum

ED_005285_00000684-00156

panels, for instance, depends on parameters such as panel design, thickness and density. While most studies show that exposure levels are not likely to be of serious concern, experience suggests that the use of phosphogypsum in building materials is not being given the attention that it perhaps deserves. Attention is often diverted too readily to other, more widely established uses of phosphogypsum such as agricultural applications. This situation appears to have been brought about by two factors in particular:

(i) Compliance with local legal criteria is often raised as an obstacle, often leading to potential uses of phosphogypsum in building materials being dismissed without consideration of the possibility that the criteria themselves might be inappropriate. Ideally, the establishment of criteria for the use of phosphogypsum would be based on empirical scientific evidence relevant to the local situation and would take account of prevailing economic and social factors. Not surprisingly, perhaps, the criteria tend to be based, instead, on a more simplistic approach using theoretical modelling, which is likely to be generic, conservative and limited to purely radiological considerations. Consequently, the criteria end up being unnecessarily restrictive.
(ii) All too often, the use of phosphogypsum is considered only on its direct technical and economic merits as a substitute for other building materials such as natural gypsum (which, in many countries, is in good supply at a competitive price). The broader, less direct benefits of using phosphogypsum in building materials, particularly the additional opportunity that it offers for reducing the financial and environmental liabilities associated with the indefinite storage of phosphogypsum, are not taken into consideration.

Phosphogypsum has also been used in some countries in civil construction applications other than buildings and roads. For instance, the phosphogypsum produced by the largest wet process phosphoric acid plant in China has been used for civil engineering projects such as the construction of the Three Gorges Dam [33], which accounts for nearly 80% of the annual production from the plant.

10.5.2.1. Phosphogypsum in cement

The use of phosphogypsum in cement and related products such as plaster provides an opportunity for consuming large volumes of material. Various options have been pursued in several countries [187–189]. In Europe, the use of phosphogypsum in this manner was well established from the 1960s onwards. In

ED_005285_00000684-00157

former phosphogypsum producing countries such as Belgium and France, the opportunities for significant commercial benefit from the use of phosphogypsum in cement and plaster led to investigations being focused on these applications rather than on other construction applications such as road construction [190].

In Spain, activity concentration measurements were made on two types of cement containing phosphogypsum [185]. The results of the measurements are given in Table 34 — the phosphogypsum used in this application is identified as PG-1 and PG-2. The activity concentrations of ^{226}Ra, ^{210}Pb and ^{210}Po in the cement were much lower than those in the phosphogypsum. The activity concentrations of ^{40}K were higher, while the activity concentrations of ^{232}Th were similar. The significant dilution of activity content indicates the potential for use of phosphogypsum in building materials. Detailed information based on dose assessments can be used to determine further the applications of phosphogypsum as an additive to cement for building applications on a case-by-case basis.

10.5.2.2. Phosphogypsum panels

In a study conducted in Brazil [191–193], exposure levels were measured inside an experimental house constructed using relatively thin, high strength phosphogypsum panels. The walls were composed of double sets of joined panels with a thickness of 1.5 cm and a 15 cm gap between two such joined panels. For ceiling panels the thickness was 1 cm. The house is shown in Fig. 48. The mean radionuclide activity concentrations in the phosphogypsum panel material from three production locations were 0.02–0.39 Bq/g for ^{226}Ra, 0.03–0.85 Bq/g for ^{210}Pb, 0.03–0.25 Bq/g for ^{232}Th and <0.08 Bq/g for ^{40}K. For various realistic scenarios involving the exposure of a house occupant, the projected average incremental dose was found to be 0.02–0.20 mSv/a, with the range of values

TABLE 34. ACTIVITY CONCENTRATIONS IN PHOSPHOGYPSUM AND IN CEMENT CONTAINING PHOSPHOGYPSUM

Material	Activity concentration (Bq/g)				
	Ra-226[a]	Pb-210	Po-210	Th-232[a]	K-40
Phosphogypsum PG-1	0.205	0.161	0.214	0.019	—
Phosphogypsum PG-2	0.170	0.165	0.174	0.006	0.013
Cement 1	0.027	<0.056[b]	0.021	0.017	0.730
Cement 2	0.027	<0.036[b]	0.025	0.013	0.613

[a] The activity concentrations of Ra-226 and Th-232 were determined by equating them to the measured values of Bi-214 and Ac-228, respectively.

[b] Detection limit.

ED_005285_00000684-00158

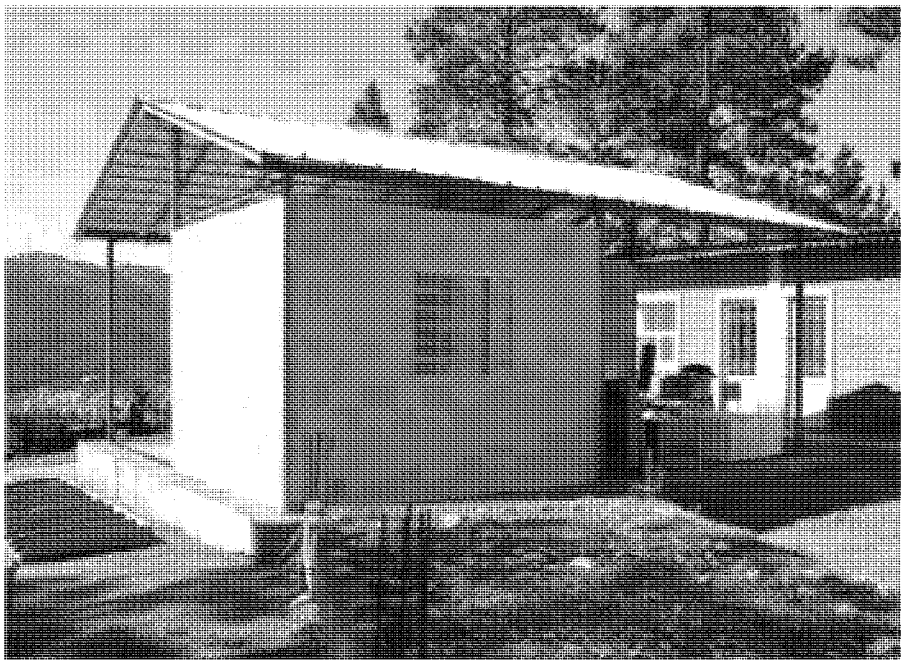

FIG. 48. An experimental house constructed using phosphogypsum.

reflecting the different origins of the phosphogypsum. The radon concentrations measured in the experimental house were found to be 45–119 Bq/m^3, averaged over a period of 15 months, changing detectors every three months. No information on the ventilation conditions in the experimental house was available. However, on the basis of the available data, radon could possibly be an exposure pathway in buildings constructed using phosphogypsum with high radium concentrations.

The use of phosphogypsum plasterboard panels in house construction has also been studied in Australia [194, 195]. The annual effective dose received by the occupant of a room of dimensions 5 m × 5 m × 3 m was calculated, assuming that the walls and ceiling were lined with 1 cm thick phosphogypsum panels having a ^{226}Ra activity concentration of 0.4 Bq/g. The annual effective dose attributable to the phosphogypsum was 0.13 mSv, representing an increment over that for normal construction of 14%. On the basis of measurements made on the panels to determine their ^{226}Ra content and ^{222}Rn exhalation rate, exposure to radon progeny was calculated by modelling a typical building configuration. The measured ^{222}Rn exhalation rates in the untreated plasterboard were in the range 0.0005–0.001 Bq·m^{-2}·s^{-1}. For air exchange rates greater than 0.5 and up to 5 air changes per hour, the incremental annual effective dose from radon progeny

ED_005285_00000684-00159

inhalation was found to be between 0.02 and 0.16 mSv for the maximum measured radon exhalation rate. It was also found that the radon exposure was reduced if the surfaces of the panels were coated with paint or cardboard. Exposure was also reduced by 15–20% if the very fine particles were removed from the phosphogypsum prior to manufacture of the plasterboard. The annual effective dose received via the inhalation of airborne dust by a worker installing the plasterboard was also determined, based on certain assumptions. For particles with an AMAD of 5 μm and having an initial source concentration of 0.4 Bq/g ^{238}U and progeny in equilibrium and a dust concentration of 1 mg/m^3, the inhalation dose was estimated to be 0.05 mSv for an exposure period of 2000 h.

The use of phosphogypsum in building and construction materials has also been investigated in India [196]. Measurements carried out inside a plasterboard plant showed absorbed dose rates in the range 0.03–0.04 μGy/h in the phosphogypsum mixer, aligner, tensioner and hammer mill areas. Higher absorbed dose rates up to 0.1 μGy/h were measured in the product storage area. The mean radionuclide activity concentrations in the 1.25 cm thick plasterboard sheet were 0.09 Bq/g for ^{226}Ra, 0.009 Bq/g for ^{238}U, 0.005 Bq/g for ^{232}Th and 0.015 Bq/g for ^{40}K. Various exposure scenarios were postulated and a dose estimation for each of these scenarios was carried out using methodologies reported elsewhere for the assessment of radiation exposures from building materials containing radionuclides. The maximum doses estimated for the use of phosphogypsum panels in ceilings, walls and floors were in the range 0.15–0.46 mSv/a. Exposure to radon exhaled from the material was not considered, as it was not a significant exposure pathway under the prevailing ventilation conditions. In formulating a regulatory guideline, glass fibre reinforced phosphogypsum panels having dimensions of 12 m × 3 m × 1.25 cm with 48 hollow cavities were evaluated for likely exposures and indicated doses as high as 4.5 mSv/a. However, by restricting the ^{226}Ra concentration in the phosphogypsum to below 1 Bq/g and by applying a surface activity concentration limit of 40 kBq/m^2, the dose could be limited to 0.3 mSv/a. The regulatory guidance also suggested mixing with other ingredients such that the ^{226}Ra concentration in the bulk material is less than 1 Bq/g.

10.5.2.3. Phosphogypsum in glass and glass ceramics

Glass and glass ceramics can be readily manufactured from phosphogypsum and tailings sand [197–201]. Since the materials are vitrified, they exhibit low radon emanation fractions. Products include:

(a) Glass ceramic floor, wall and roof tiles;
(b) Synthetic wollastonite ($CaSiO_3$) fibres used in ceramics and paints and as a non-toxic substitute for asbestos;

ED_005285_00000684-00160

(c) Synthetic stone for building facades;
(d) Abrasives;
(e) Flat 'privacy' glass;
(f) Container glass for selected beverages and agricultural products.

An assessment of doses received by a house occupant as a result of gamma radiation from the use of phosphogypsum in tiles is reported in Ref. [197]. In a typical exposure scenario, the tiles were assumed to be used on the floors of the kitchen, bathroom and entrance hall and on the walls of the bathroom, with the following dimensions:

(a) Tile thickness: 7.6 mm.
(b) Kitchen floor: 5 m × 5 m.
(c) Bathroom and entrance hall floors: 3 m × 3 m.
(d) Bathroom walls: 2 m × 3 m.

The distance from the source was assumed to be 1 m for floor tiles (or 0.2 m for a child) and 0.5 m for wall tiles. The results of the dose assessment for this typical exposure scenario are given in Table 35. Results for what is considered to be an extreme exposure scenario, involving a longer annual exposure period associated with a single 10 m × 10 m room having 7.6 mm thick floor tiles and 10 mm thick roof tiles (unshielded), are also given in Table 35. The most exposed adult is estimated to receive an annual dose of 0.06 mSv (or 0.29 mSv for the extreme scenario), while the most exposed child receives 0.09 mSv (or 0.46 mSv for the extreme scenario).

The use of phosphogypsum glass ceramic tiles in a house has also been investigated in a modelling study with respect to exposure to radon [197]. The material was assumed to consist of CaO and SiO_2 at a mass ratio of 1:3 and to have a ^{226}Ra activity concentration of 0.88 Bq/g, a density of 2600 kg/m^3 and radon emanation of 0.00021 $Bq \cdot m^{-2} \cdot s^{-1}$. The analysis showed that for a house tiled completely with phosphogypsum tiles, the radon exhalation rate was only 10% of that for normal construction materials.

10.5.3. Construction of roads

One of the more widely studied and tested uses of phosphogypsum in construction is for road building [130, 132, 202]. Unpaved phosphogypsum roads are commonplace at phosphoric acid production facilities, especially on and around phosphogypsum stacks. Initial work on the use of phosphogypsum for the construction of paved roads in Belgium [203, 204] and France [205–208] in the 1970s and 1980s focused on its use in embankments [209, 210] and for road

ED_005285_00000684-00161

TABLE 35. EXPOSURE TO CERAMIC TILES MADE WITH PHOSPHOGYPSUM [197]

Location	Absorbed dose rate (μSv/h)		Annual occupancy period (h)		Annual effective dose (mSv)	
	Adult	Child	Adult	Child	Adult	Child
Typical exposure scenario:						
Kitchen	0.025	0.058	2000	1200	0.05	0.07
Entrance hall	0.016	0.048	65	65	<0.01	<0.01
Bathroom, floor	0.016	0.048	250	250	0.004	0.012
Bathroom, walls	0.024	0.024	250	250	0.006	0.006
Total					0.06	0.09
Extreme exposure scenario:						
Floor	0.040	0.070	4500	5250	0.18	0.37
Roof	0.024	0.017	4500	5250	0.11	0.09
Total					0.29	0.46

stabilization [211]. These efforts came to an end for commercial reasons whereby the phosphogypsum under investigation had a more valuable market outlet in wall boards for buildings than in road construction. While some investigative work on the use of phosphogypsum in embankments continued elsewhere [212], ongoing work became focused on the road bed, where phosphogypsum mixed with 5–7% cement and, in some cases, fly ash emerged as the best option [132]. The construction of pilot roads built in this manner has been successfully carried out in climatic regions with wet–dry cycles, such as in Florida, USA [186, 213], South Africa [214] and in climatic regions with freeze–thaw cycles such as in Finland [215]. Although no further paved roads have been built, research into the optimization of the use of phosphogypsum in road construction has continued [216, 217].

It has been determined that the use of phosphogypsum in road base applications could consume 25 000 t per lane kilometre, which would translate into an annual phosphogypsum consumption of some 140 million t in the USA alone. It has also been determined from the pilot studies carried out that the use of phosphogypsum as a road bed material is no more expensive than the use of more

ED_005285_00000684-00162

traditional materials and may actually be less expensive when the full life cycle cost is considered [214]. In Florida, USA, in areas near large quantities of readily available phosphogypsum, the construction cost was found to be close to one third of the cost of using conventional material. With regard to resource conservation and recycling, the pilot studies indicate a potential virgin resource saving of up to two thirds [215]. The major constraints on the use of phosphogypsum in road construction are economic, cultural and regulatory:

(a) Economic constraints [218]: Owing to transport costs, any bulk material used for road construction needs to be readily available from a source located reasonably near the construction site. For phosphogypsum to be viable as a road construction material, it has been estimated that its source would have to be located no more than 150–200 km from the construction site [219].
(b) Cultural constraints: Road builders seem reluctant to substitute phosphogypsum for conventional road bed materials. To overcome such reluctance, a shift in attitudes towards the use of phosphogypsum would be necessary [132]. It has been suggested that the offer of some initial incentive would eventually change current perceptions concerning the use of phosphogypsum, similar to the way in which perceptions in the cement industry have changed from considering fly ash as a waste to considering it as a valuable resource [132].
(c) Regulatory constraints: Even where the environmental impact is considered acceptable once the road is built, other regulatory constraints may still exist. In the USA, for instance, the use of phosphogypsum for road construction is, in effect, prohibited because authorization cannot be obtained for the transport of the material to the construction site [220].

10.5.3.1. Technical considerations

Phosphogypsum has successfully been used as a binder for base course mixtures. Phosphogypsum based mixtures are more workable than clay based mixtures. Delays due to rain during construction are reduced because the compacted mixture does not absorb significant amounts of water. Shrinkage cracks and swelling, which often negatively affect the performance of clay based road beds, are greatly reduced. The stability of compacted phosphogypsum mixtures is superior to that of clay mixtures [186] and there is evidence that the use of phosphogypsum, if correctly optimized, leads to a progressive strengthening of the road bed over time [214, 215].

In Texas, USA, road bases for city streets, shopping centres, truck terminals, parking lots and loading platforms were successfully constructed using

ED_005285_00000684-00163

cement and fly ash stabilized phosphogypsum and fluorogypsum[23] [221, 222]. This was followed, in 1988–1991, by the construction of several experimental sections of road directed towards establishing materials selection criteria, a suitable mix design rationale and construction procedures to permit stabilized phosphogypsum road bases to be used in Texas [223]. The concepts generated were successfully demonstrated in 1991 when a two lane 100 m test section was constructed using a road base consisting of a 7% cement stabilized phosphogypsum mixture with an unconfined seven day compression strength of 3.1 MPa. A second experimental test section was constructed in 1992 using a road base containing equal proportions of bottom ash (comprising three parts boiler slag to one part cinder ash) and phosphogypsum. Two additional road sections were built in 1993 using phosphogypsum blended with fly ash and cement–fly ash, respectively [132]. After two years, these sections were found to be performing well.

In Florida, USA, two experimental roads were built in 1986–1987 using both dihydrate and hemihydrate forms of phosphogypsum [224, 225]. The results of the evaluations are reported in Refs [226–228]. It was concluded that phosphogypsum, when subjected to optimum mixing and compaction, could be transformed into a solid of high strength that is effective as a binder to stabilize on-site soil. Phosphogypsum and sand mixtures, stabilized with a small amount of cement, possessed a load bearing capacity higher than that of locally mined limestone, which was at that time the material of choice for road bases in the region. It was also demonstrated that the incorporation of phosphogypsum into a cement based mixture for making 'roller compacted concrete' (a form of concrete widely used for road construction) led to improved compaction and strength properties [229]. The road bed described in Ref. [224] is shown in Fig. 49, which shows the condition after 25 years of use. The picture was taken during routine resurfacing. While the phosphogypsum is clearly not mixed in fully with other road bed materials, it has, neverthless, lost none of its load bearing strength. As a result, the only maintenance requirement was a new layer of asphalt.

10.5.3.2. Environmental impact

The dissolution and/or leaching of the road bed mix, especially the phosphogypsum component, and any volume change due to changes in water content and/or chemical reactions were evaluated in terms of their potential environmental impact [228]. Laboratory tests showed that leaching from cement

[23] Fluorogypsum is a residue from the production of hydrofluoric acid.

ED_005285_00000684-00164

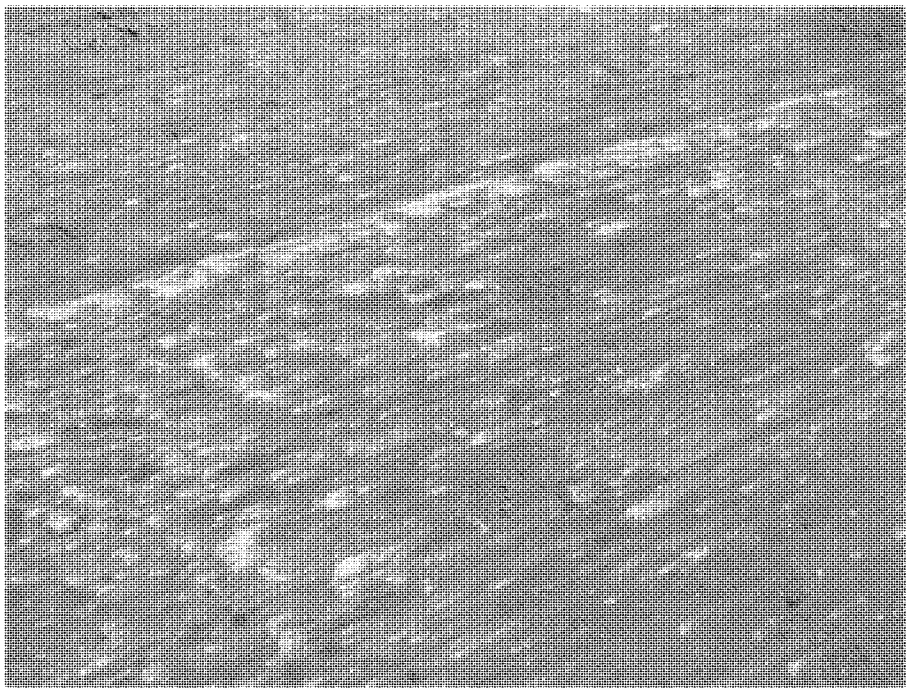

FIG. 49. Experimental road bed in Florida, USA, incorporating phosphogypsum (courtesy: Florida Industrial and Phosphate Research Institute).

stabilized phosphogypsum was below levels of concern, even in the TCLP[24] test designed to simulate the leaching of toxic elements such as mercury and cadmium from material disposed of in a landfill facility. It was found that the leaching of heavy metals into the environment from the phosphogypsum component was lower than that from the cement component. The processes of compaction and cementation were shown to be effective in reducing the leaching of salts. (Compaction also reduced radon exhalation.) It was concluded that no significant leaching of any potentially harmful component of the cement stabilized materials would occur, even where the road base was exposed to free water. The water environment under a road does not change very quickly, since the road bed has a low permeability and the road surface is designed to be impermeable.

The environmental impact of the experimental road bases constructed in Texas, USA, in the early 1990s was evaluated through TCLP analysis of the

[24] TCLP: Toxicity characteristic leaching procedure.

ED_005285_00000684-00165

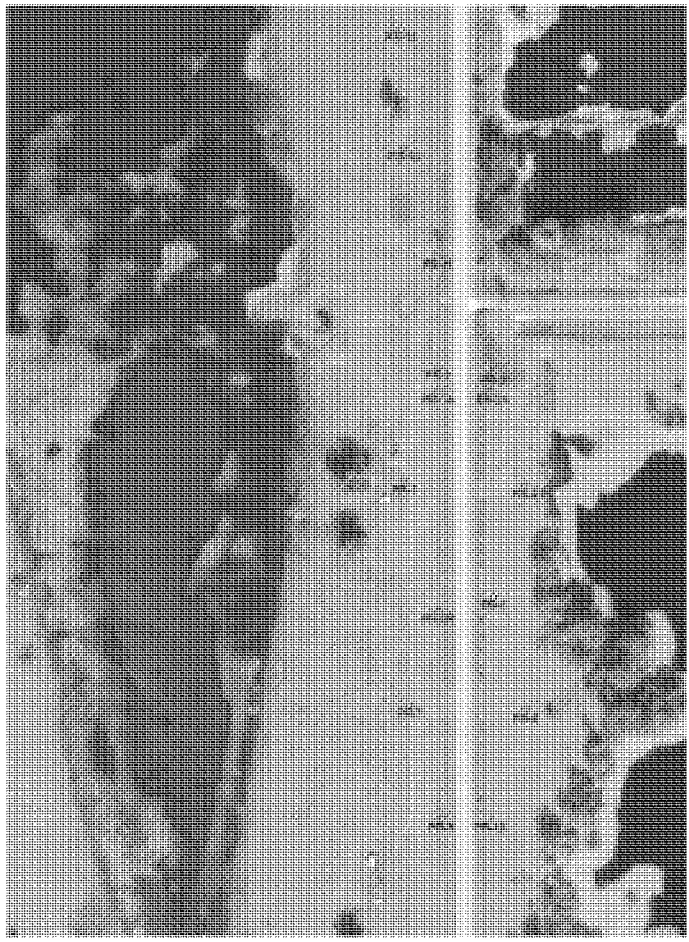

FIG. 50. Aerial view of an experimental road in central Florida, USA, showing the positions of the monitoring wells (courtesy: Florida Industrial and Phosphate Research Institute).

mixture components along with analysis of the groundwater, surface water and leachates [221]. The concentrations of leached chemicals were found to be below levels of environmental concern and in many cases negligible. In central Florida, USA, groundwater monitoring adjacent to one of the two experimental roads constructed in 1986–1987 was undertaken four months prior to construction and thereafter for 27 further months, resulting in a total monitoring period of 31 months [230]. Follow-up monitoring continued until 2008. The positions of the monitoring wells relative to the road are shown in Fig. 50. No significant impact on the groundwater was detected, with the concentrations of leached chemicals all remaining below levels of environmental concern [231].

ED_005285_00000684-00166

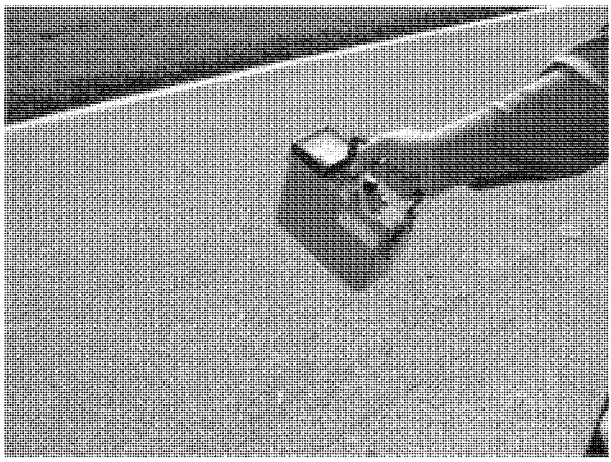

FIG. 51. Monitoring of gamma radiation above an experimental road in Florida, USA (courtesy: Florida Industrial and Phosphate Research Institute).

Groundwater monitoring of the second of the two experimental roads constructed in 1986–1987 was carried out in a similar manner and, again, the experimental road was found to have no measurable impact on the quality of the groundwater.

10.5.3.3. Radiological impact

The two experimental roads constructed in Florida, USA (see Section 10.5.3.1), were subjected to a radiological assessment by monitoring the air, soil and groundwater before and after construction [230]. The monitoring addressed gamma radiation (see Fig. 51), outdoor radon and ^{226}Ra in samples of water and soil. From the results of gamma exposure measurements, it was determined that the absorbed dose rates 1 m above the paved road surface were 0.015–0.035 μGy/h higher than pre-construction values and did not change appreciably over time. These incremental dose rates are within the normal range of variability of background levels. The radon concentrations measured in the air and soil after construction were not significantly different from those measured before construction [232]. The same was found to be the case for the activity concentrations of ^{226}Ra measured in the groundwater (over a one year period) and the soil around the experimental roads. It was concluded, therefore, that the construction of the roads had had no appreciable effect on radon and ^{226}Ra levels in the surrounding environment.

Gamma radiation monitoring was also carried out above an experimental road surface made from roller compacted concrete containing phosphogypsum (described in Section 10.5.3.1) [229]. The absorbed dose rate 1 m above the road

ED_005285_00000684-00167

surface was determined to be 0.009 μGy/h, about 50% lower than that recorded above a nearby asphalt road (0.020 μGy/h) and about 25% lower than that recorded above a nearby non-paved surface (0.012 μGy/h).

10.5.4. Marine applications

Many phosphogypsum stacks are located around low lying coastal areas and the use of this phosphogypsum in marine applications is therefore an attractive proposition from an economic point of view. Marine applications of phosphogypsum offer many potential benefits, including the stabilization of vulnerable coastlines, the protection of areas such as coastal wetlands against the risk of flooding and the re-establishment of coastal industries such as shellfish production.

Research has focused on the stability of mixtures of phosphogypsum, fly ash and cement in seawater environments and their effect on the surrounding marine environment, with particular attention being given to the suitability of such mixtures for making oyster cultch or artificial reefs [233–239]. Mixtures containing various proportions of phosphogypsum (55–73%), cement (2–10%) and fly ash (25–42%) have been found to suffer little degradation in sea water over periods of up to two years. A key factor in creating resistance to degradation in sea water and reducing the diffusion of heavy metals and ^{226}Ra is the formation of a calcite ($CaCO_3$) surface layer that acts as a physical barrier to seawater intrusion. The inclusion of fly ash in the stabilized phosphogypsum mixture promotes the formation of such a layer while limiting the required cement content to only 2–3%. The leaching of heavy metals and ^{226}Ra from stabilized phosphogypsum is comparable with that from pure cement and well below levels that might be of concern for health. Tests in the field have shown that stabilized phosphogypsum mixtures are capable of supporting the growth of oysters and other shellfish and do not lead to any significant bioaccumulation of heavy metals in fish.

10.5.5. Landfill

Phosphogypsum has been shown to have good potential for use as a cover material in landfill disposal facilities [240–242]. In Italy, phosphogypsum has been used experimentally as a liner for landfill on the edge of the Venice lagoon [243]. Laboratory studies and pilot scale testing indicate that the sulphur in the phosphogypsum increases the biological activity in the buried refuse. The increased rate of degradation allows 30–45% more waste to be buried in a given volume of landfill, thus considerably extending the useful life of the facility. Since an industrial landfill facility is designed to isolate the waste from the surrounding environment, for instance through the use of an impervious liner, it is highly unlikely that the additional amounts of heavy metals and ^{226}Ra introduced

ED_005285_00000684-00168

through the phosphogypsum would lead to any significant environmental or radiological impact.

10.5.6. Sulphur recovery

The use of phosphogypsum as a source of sulphur has been studied extensively. Many process routes, both chemical [244–249] and biological [250–252] have been explored, but all require considerable energy inputs. With the availability of low cost by-product sulphur from the oil and gas industry, the recovery of sulphur from phosphogypsum is unlikely to be competitive from a purely economic point of view. However, because of the considerable financial implications associated with the continued storage of phosphogypsum in stacks, the use of phosphogypsum as a source of sulphur could become worthwhile from a broader perspective, particularly since, in the chemical recovery process, the radionuclides in the phosphogypsum appear to migrate to the calcium carbonate by-product, leaving the ammonium sulphate intermediate product free of radioactivity [253]. The radiological aspects of biological recovery processes have not been studied, but it can be expected that the radionuclides would remain in the residue after removal of the sulphur content, leaving the sulphur essentially free of radioactivity.

10.5.7. Other uses

Phosphogypsum has many other uses that have proven to be successful and economic, although the amounts of material involved are generally small. Such uses include:

(a) Treatment of industrial waste:
  (i) Bauxite waste [254];
  (ii) Coal mining waste (removal of barium and radium) [255];
  (iii) Metal finishing waste [256];
  (iv) Textile waste (removal of colour and organics) [257].
(b) Agricultural applications:
  (i) As a binder for fertilizer [258];
  (ii) As an additive to bauxite residue for use in improving phosphorus retention in sandy soil [259].
(c) As an additive for improving the performance of bauxite residue drilling mud [260].
(d) As a filler for 'plastic wood' [261].
(e) As a de-icing additive [262].

ED_005285_00000684-00169

10.6. DISPOSAL OF PHOSPHOGYPSUM

The rate at which phosphogypsum is produced far exceeds the rate at which it is used. In addition, very large stockpiles of phosphogypsum from past production are held in indefinite storage in stacks (see Section 10.1). Unless this phosphogypsum can be put to good use in the foreseeable future, the need for the disposal of large amounts of phosphogypsum will remain. The most common methods of disposal are in situ disposal through stack closure and discharge to water bodies as a dilute slurry. Relatively small amounts of phosphogypsum are also disposed of by backfilling in mined-out areas.

10.6.1. In situ disposal through stack closure

10.6.1.1. Evolution of the approach to closure

The worldwide trend has been for production facilities to become consolidated, resulting in significant increases in production capacity. This has created a tendency to close older, smaller phosphogypsum stacks and to plan for a smaller number of very large ones. As an example, an older type of stack was closed on the edge of Tampa Bay in Florida, USA, in 1992. At the time of closure, the stack covered a land area of 138 ha and its height was 66–69 m. During operation, it was growing in height at a rate of about 6 m per year [263]. Some older stacks were not formally closed, having been abandoned by their owners, and have tended to blend into the landscape over time as a result of local vegetation establishing itself on the stack surface.

Stack closure has become significantly more common in major production centres such as those in Florida, USA, as the industry scales back production or stacks reach their maximum usable height. The closure process in Florida is subject to a formal procedure involving the establishment of detailed specifications and resulting in a published plan, usually subdivided into phases [264, 265]. The Tampa Bay stack closure [263] was completed in just over a year (1992), while a stack at Piney Point required more than two years to close [266].

Although closures of production facilties have become more commonplace since the 1990s, closure of the associated stacks has tended to be carried out in an unplanned or unforeseen way, often as a consequence of the bankruptcy of the producing company. There has been a lack of forward planning, particularly where the closure of production facilities has marked the end of national production capacity. Owing to inadequate communication within and between countries, the lessons learned from stack closure at one site have not been transmitted to other sites. Instead, the approach to stack closure has been ad hoc in nature, resulting in inconsistency between sites and unnecessarily high costs.

ED_005285_00000684-00170

The situation is now changing, however. At some sites, such as that at Huelva, Spain, planned closure is now being pursued actively, leading to the emergence of some best practices that could beneficially be passed on to other sites in due course.

For new production facilities, the adoption of a complete life cycle approach, in which eventual stack closure forms an integral part of the planning of the facility, brings substantial benefits. These include reduced financial and environmental burdens and better prospects for the eventual use of the phosphogypsum, the pond water and the land (thus offsetting the costs of stack closure). One of the many implications of such an approach is that it would put an end to the common practice of burying waste indiscriminately in the stack with no records and, instead, lead to the implementation of a standard operating procedure that designates specific areas for burial with an associated long term management plan. In terms of the life cycle approach, any new facility would have in place, from the outset, a clear plan for stack closure that would be sufficiently detailed to enable the proper financial provision to be included in the planning of the facility as a whole. Lessons learned at facilities such as Gela, Italy, and Piney Point, USA, have shown that the magnitude of this financial provision could be very large. This could have significant implications for countries building production facilities for the first time or which are significantly increasing their current levels of production. The large capital investment required to establish a facility combined with the need to make adequate provision for closure costs could threaten the success of the business enterprise from the outset. This underlines the need for making sensible and well thought out policy and regulatory decisions so that these 'negative externalities' are no greater than they need to be.

10.6.1.2. The closure process

The older the stack, the more likely is the occurrence of problems in the closure process, especially problems related to the very large volumes of process water contained on top of, or within, the stack. Closure activities associated with the stack itself and with the stored process water are interdependent. When the storage capacity of a phosphogypsum stack is exhausted or when a production facility is permanently closed, not only the pond water but also the seepage and rainfall runoff have to be contained within the site and/or treated before discharge. This has to continue for as long as rainwater is able to infiltrate the stack and/or until the water in the pores of the phosphogypsum has drained out. In addition, prolonged rainwater infiltration will produce a network of dissolution cavities that could make it more expensive to cap the stack at a later date.

ED_005285_00000684-00171

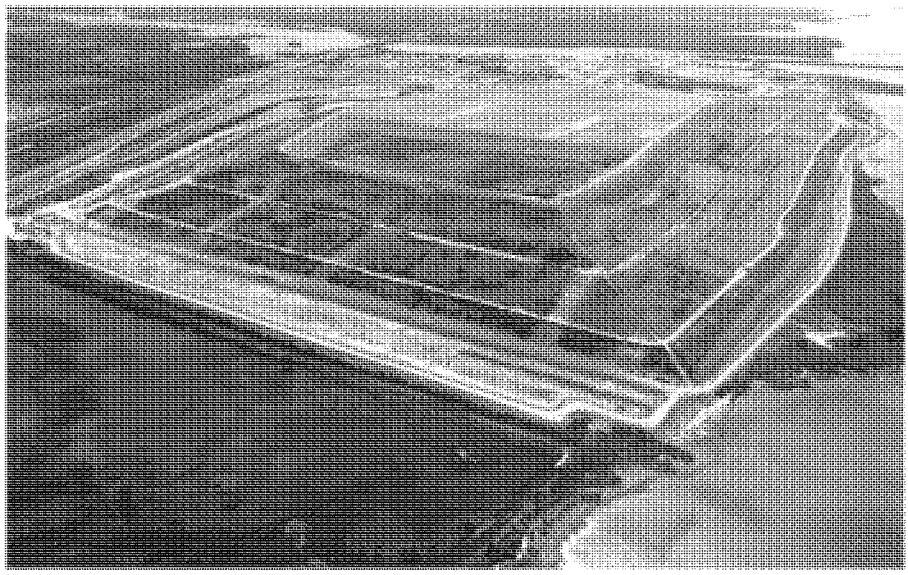

FIG. 52. A computer modified image of the regrading of a stack as part of the closure process (courtesy: Fertiberia, Spain).

Regrading and revegetation of the side slopes, after any necessary surface treatment with dolomitic limestone to rectify magnesium deficiency in the topsoil, may often be sufficient to prevent rainfall (and snow melt) from seeping into the slopes and may thus allow for subsequent runoff to be discharged from the site without treatment. Under favourable climatic conditions and hydrogeological settings, regrading of the top of a gypsum stack to promote surface runoff in combination with good vegetation and/or a relatively impervious clay cover may be sufficient to prevent rainfall infiltration. In other situations, capping with an impervious geosynthetic barrier may be needed. A stack undergoing regrading is shown in Fig. 52.

Revegetation of phosphogypsum stacks is greatly facilitated by the fact that phosphogypsum performs well as a soil. An example of revegetation at a site in Italy is shown in Fig. 53. At this site, stack closure was carried out as part of the total decommissioning of the phosphoric acid production facility — this is possibly the first global example of such an integrated approach to decommissioning and closure. The integrated approach also opens up the possibility of controlling the sequence of activities such that the process equipment in the plant can be used to facilitate stack closure. At the Piney Point facility in Florida, USA, for instance, the cost of stack closure was reduced by redeploying equipment in the phosphoric acid plant to treat the acidic pond water instead.

ED_005285_00000684-00172

FIG. 53. Planned revegetation of a stack at Gela, Italy.

Once infiltration into the stack has been eliminated, the stack will continue to drain until any settling due to consolidation and creep is complete and the moisture in the phosphogypsum pores reaches its maximum retention capacity. Overall, drainage depends on the dimensions and age of the stack, the properties of the phosphogypsum and the hydrogeological setting. A stack constructed on porous ground will drain much more rapidly than one constructed on low permeability clay.

10.6.1.3. Removal of closed stacks

Stack closure is not an irreversible process and it is, therefore, possible for all or part of the phosphogypsum contained within a closed stack to be subsequently retrieved for use. One important consideration in the reopening of a closed stack for this purpose is the presence of other waste materials within the stack that may have significant levels of contamination. One option is for these materials to be reburied within the remnants of the stack. Alternatively, they may be transported to another disposal site.

A stack may also be removed in order to make use of the land on which it stands. The spread of urban development is bringing populated areas ever closer to older stacks, many of which are no longer in operation. Examples of this

ED_005285_00000684-00173

FIG. 54. New housing development next to a phosphogypsum stack at Gela, Italy.

situation can be found in Greece, Italy (see Figs 54 and 55) and Spain (see Fig. 56). In Greece, the city of Athens has actually engulfed a stack associated with a former production facility, with only the surface of the stack itself remaining free of buildings. Owing to the growth in real estate values at many of these sites, there is increasing interest in removing some of these older stacks and remediating the land for development. Developers have indicated an interest in removing a stack at Thessaloniki, Greece, in order to develop the site for residential purposes. A similar situation exists in the Tampa Bay region of Florida, USA, where property developers are seriously evaluating the costs of remediating contaminated sites to enable their use for residential development. Production facilities are often situated in coastal areas that have become increasingly prized by property developers. These sites may offer a good financial return if they can be brought back into consideration for building purposes, especially residential housing. The freeing of land for public use by stack removal has already brought community-wide benefit, as illustrated by examples in Athens, Greece [267], and Sfax, Tunisia [268], where new recreation facilities have been established on the remediated sites. More information on the remediation of a phosphogypsum stack in Tunisia is provided in Annex II.

ED_005285_00000684-00175

10.6.1.4. Radiological aspects

The closure of a stack, when conducted in a planned and effective manner, ensures that any future migration of potential pollutants, such as acidic water, heavy metals and radionuclides, remains at acceptably low levels. Thus, the radiological impact on members of the public living nearby is insignificant. Extensive monitoring carried out over many years at over twenty sites in Florida indicated that radionuclide discharges from stacks and migration to groundwater are insignificant [81]. Operating experience also suggests that doses to the public from legacy sites are negligible. Many older stacks that have already been closed are legacies of former production operations and may not have been closed in accordance with current standards. In such cases, the radiological (and non-radiological) impacts may be greater than those considered acceptable in terms of current standards. Where this is found to be the case, a decision on possible remediation (or removal) would have to be taken by the relevant national authority, bearing in mind that the costs involved could be very high.

10.6.2. Discharge to water bodies

It has been estimated that, up to 2006, a worldwide total of 1.8–3.0 billion t of phosphogypsum had been disposed of by discharge to water bodies, representing 29–50% of all phosphogypsum produced up to that time (see Table 32). This form of disposal was at one time practised widely in Europe. However, as a result of the progressive imposition of legal restrictions on this form of disposal, most phosphoric acid production in Europe (and thus the discharge of phosphogypsum) has now ceased. The situation in the USA and China has been much the same. Discharges to water bodies are currently running at about 31 million t per year, representing 19% of the total amount of phosphogypsum produced annually worldwide. All of these discharges occur in countries outside Europe and the USA, where, on average, they account for about 30% of those countries' current phosphogypsum production. Further information on discharges of phosphogypsum to water bodies is given in Table 36.

The discharge of phosphogypsum as a dilute slurry to the sea has been practised on a large scale by phosphoric acid production facilities situated at coastal locations. In principle, given appropriate conditions in the receiving waterbody, the environmental impact of this form of disposal is apparently negligible. Such conditions were not considered to prevail in the case of discharges to water bodies such as the Irish Sea, the North Sea and parts of the Mediterranean, however, and such discharges have now ceased [269]. For example, discharges into the North Sea from a phosphoric acid facility at Sellafield, UK, were found to have led to the uptake of radionuclides by marine

ED_005285_00000684-00176

TABLE 36. DISCHARGE OF PHOSPHOGYPSUM TO WATER BODIES, BY COUNTRY

Country	Status of discharges
Canada	Former discharges to the bay and inland sea have now ceased.
China	25% of phosphogypsum was discharged to rivers. Discharges have now ceased.
France	Significant discharge to the river in the past and now ceased.
Lebanon	Discharges to the sea.
Morocco	All phosphogypsum is discharged to the sea. The policy for future discharges is under review.
Netherlands	All phosphogypsum was discharged to estuaries. Discharges ceased in 2001 owing to the closure of the plant because of the costs of regulatory compliance.
South Africa	Significant discharge of phosphogypsum to the sea.
Spain	20% of phosphogypsum was discharged to a river estuary. Discharges ceased in 1988.
Tunisia	Progressive termination of discharges to the sea. Discharges planned to cease entirely in 2012.
UK	All phosphogypsum was discharged to the sea. Discharges ceased in 1992, largely because of the costs of regulatory compliance.
USA	An estimated 23% of the phosphogypsum produced up to 1981 (500 million t) was discharged to rivers and to the sea. Discharges ceased in 1982.

food sources [86]. In the light of experience such as this, and because of heightened sensitivities about pollution of the marine environment in general, the discharge of phosphogypsum to the sea is widely regarded as environmentally unacceptable and in contravention of international agreements. In most countries, legislation now prohibits such discharges and the resulting financial consequences have caused many facilities to close down. As a result of these developments, discharges of phosphogypsum to the sea have, since the 1990s, been progressively curtailed [33].

A similar situation exists for discharges to other large water bodies. Discharges to major rivers such as the Yangtse in China or the Mississipi in the USA[25], as well as to estuarine environments such as that at Huelva, Spain, have ceased. Follow-up studies based on field measurements made at Huelva have indicated that, once the discharge ceases, the self-cleaning properties of flowing

[25] A phosphoric acid production facility near Taft, Louisiana, discharged phosphogypsum directly into the Mississippi River from the 1960s to the mid-1980s.

ED_005285_00000684-00177

or tidal waters can be expected to reverse the buildup of contamination back to natural background levels [270–272]. The situation at Huelva is, however, influenced by the presence of an operational phosphogypsum stack that potentially acts as an ongoing source of contamination of the estuary. The evidence suggests that, because of this, the contamination levels in the estuary, while reducing gradually, may remain elevated above background levels for some time [273]. In a study carried out by the European Commission on radionuclide discharge from the phosphate industry to north European marine waters [269], estimated discharges of 65 TBq of ^{226}Ra and ^{210}Po, together and 32 TBq of ^{210}Pb, were reported for a period of more than two decades of operation. Analysis of several marine species indicated increased accumulation of ^{210}Po, possibly attributable to discharges. Probably as a result of closure of some of the industries and technological improvements in existing processing plants, a downward trend in activity discharges was noted.

10.6.3. Backfilling into mined out areas

The pits created by the mining of phosphate ore may, in some instances, be remediated by backfilling with a blend of clay tailings from the beneficiation process and phosphogypsum obtained directly from the filtration system of the phosphoric acid plant. The high calcareous content of the clay neutralizes the acid retained within the phosphogypsum. Such an approach has been adopted at a facility in North Carolina, USA, where a unique set of hydrogeological conditions favour this method of disposal.

10.7. REGULATORY CONSIDERATIONS

The storage of phosphogypsum in stacks, irrespective of its radioactivity content, creates potential environmental and physical safety hazards and, therefore, needs to be controlled by the relevant authorities in a consistent and harmonized manner. Similar controls are necessary when a stack is undergoing closure. Evidence shows that, with such controls in place, there is no necessity for additional regulation for purely radiological purposes. Future liabilities associated with the continued presence of large phosphogypsum stacks place a considerable burden on future generations. This, together with the increasing rate of phosphogypsum production, provides a very compelling reason for creating a regulatory environment that is conducive to identifying and promoting further ways of safely using phosphogypsum as a co-product of phosphoric acid production rather than having to manage it as waste.

ED_005285_00000684-00178

For the forseeable future, the discharge of phosphogypsum to water bodies is largely being phased out but is likely to continue in some countries. Experience has shown that, to ensure acceptable levels of risk to humans and to the environment, such discharges would need to be regulated as part of an authorized practice on the basis of a situation specific risk assessment.

All evidence suggests that the doses received as a result of the use of phosphogypsum in agriculture, road construction, marine applications and in landfill facilities are sufficiently low that no restrictions on such uses are necessary. The uses of phosphogypsum in structural panels for the construction of a house could, in extreme circumstances, result in the occupant receiving an annual effective dose exceeding 1 mSv. Therefore, it would be prudent for the relevant authority to ensure that an appropriate situation specific risk assessment be carried out in order to determine whether any restrictions on this particular use of phosphogypsum are needed. For all other uses of phosphogypsum in home construction, including its use in cement, bricks, plasterboard and tiles, the annual effective dose received by the occupant is unlikely to exceed 1 mSv and restrictions on such use would appear to be unnecessary.

11. DECOMMISSIONING OF WET PROCESS PLANTS AND MANAGEMENT OF SCRAP

Given the substantial capital investment needed to construct wet process facilities, the plants are usually operated for very long periods. Some plants have been in continuous use for well over 50 years and have been in a state of continuous maintenance because of corrosion and the formation of scale and sediments. During the course of routine operations, production is suspended for short periods to allow critical items such as pipes and filter cloths to be cleaned or replaced. Thus, scrap materials are generated throughout the life of the plant, as well as during the eventual decommissioning process. With the possible exception of the decontamination of the land on which the facility is situated, the issues addressed during routine maintenance tend to be similar to those addressed during the decommissioning process.

11.1. DECOMMISSIONING

Considerable knowledge and experience is being established in connection with the ongoing decommissioning of wet process plants, notably in Western

ED_005285_00000684-00179

Europe, where production in most countries has ceased. Examples include plants in France, Italy [31], Greece [274], Netherlands [66] and the UK [68], which were forced to close as a result of new legislation that prohibited the discharge of phosphogypsum to water bodies. In order to continue operating, these plants would have been required to store phosphogypsum in stacks, a process that would have been prohibitively costly and in some cases not even possible because there was no available land on which to locate the stacks. Two such plants are shown in Figs 57 and 58. Usually, decommissioning is carried out as part of the permanent closure of the production facility, in which case the decommissioning process covers the decontamination and dismantling of the plant together with the remediation of the site. There are exceptions, however:

(a) While decommissioning typically includes the dismantling of a plant, or part thereof, a facility may be decommissioned without dismantling. In such instances, after decontamination, the existing or modified structure may be put to another use.
(b) Sometimes, an old plant may be decommissioned so that it can be replaced by a new plant on the same site. In such situations, it is now common practice to address issues such as soil contamination as part of the rebuild rather than deferring them to the time of final closure of the facility.

Normally, the decommissioning process is planned as part of the orderly termination of the business. Sometimes, however, the process is unplanned because outside intervention has become necessary following a failure of the business. In such cases, bearing in mind that an abandoned plant deteriorates rapidly, decommissioning may have to be carried out urgently.

11.1.1. Development of the decommissioning plan

The first step in the decommissioning process is the development of a decommissioning plan. This plan sets out the necessary sequence of administrative and technical actions leading to the eventual removal of some or all of the regulatory controls applied to the facility during its operation. The plan also sets out the necessary policies and procedures, which typically include the following:

(a) A health and safety policy, with allocation of roles and responsibilities;
(b) An outline procedure for dismantling the installation, with flowsheet and timeline;

ED_005285_00000684-00180

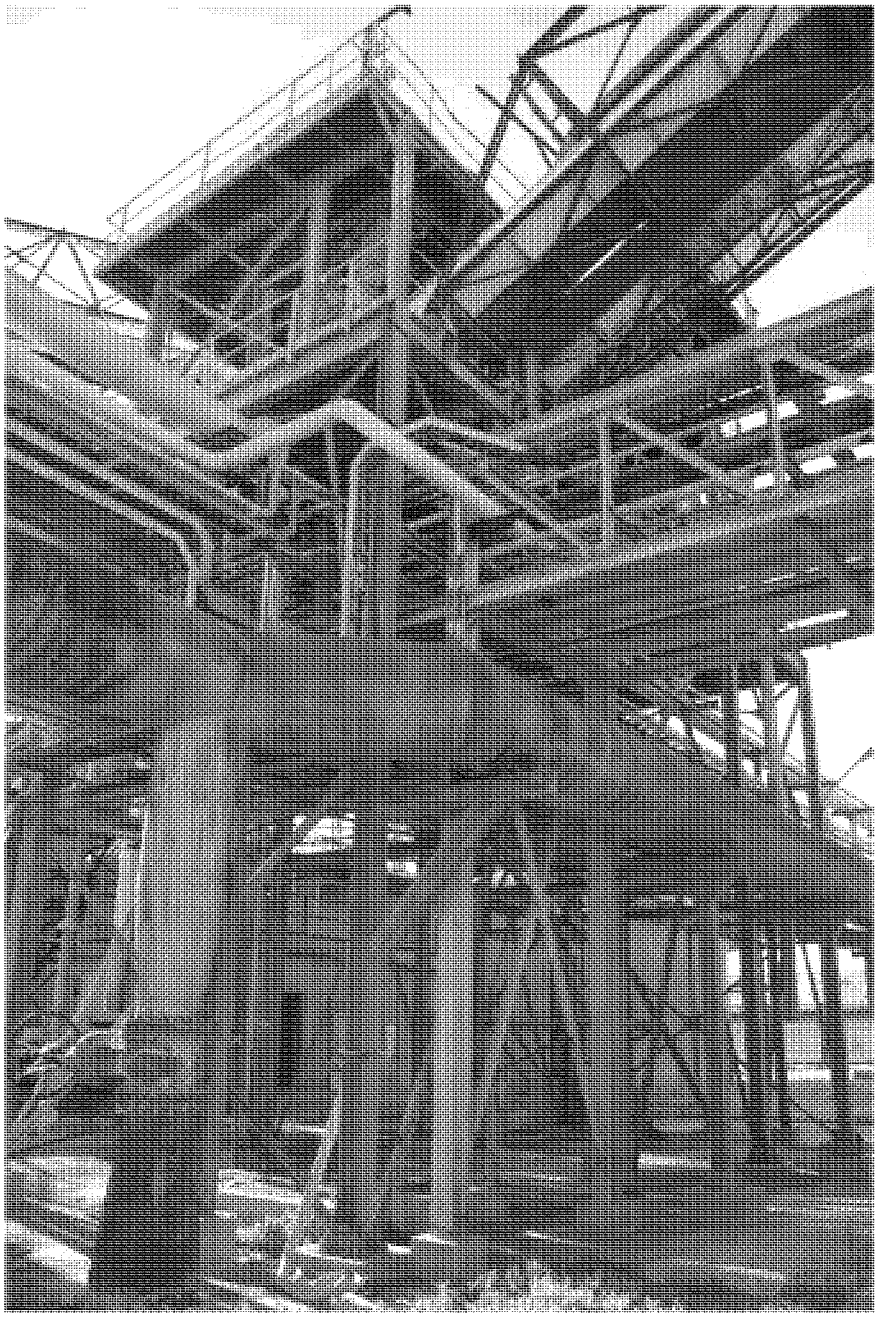

FIG. 57. A deteriorating phosphoric acid plant awaiting dismantling.

ED_005285_00000684-00181

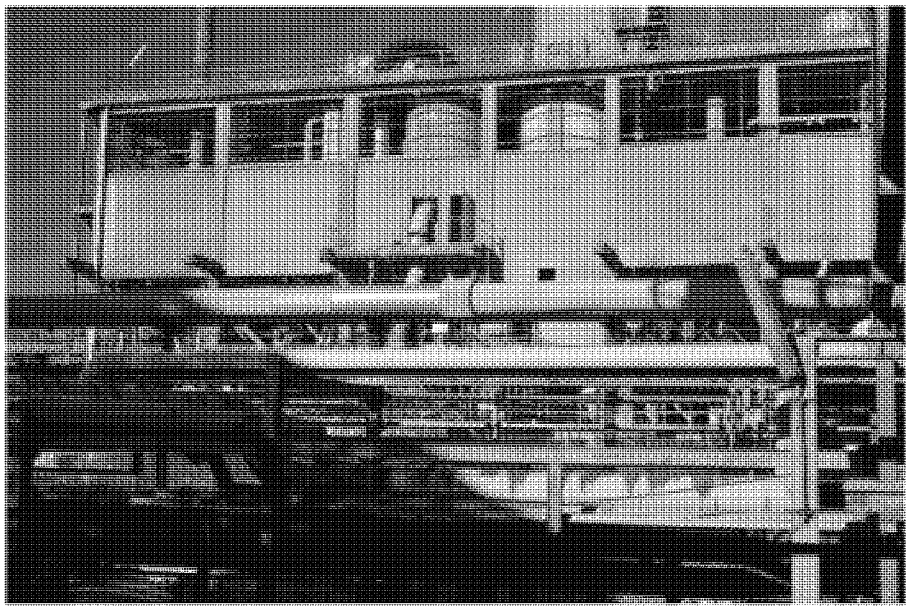

FIG. 58. A wet process plant at Gela, Italy, during decontamination and dismantling.

(c) Procedures for the flushing of process lines, the cleaning of vessels and the categorization of wastes as hazardous, radioactive or mixed;
(d) Standard operating procedures for contractors and third parties, with training and certification requirements as appropriate;
(e) A methodology for the treatment, transport and disposal of scale, other radioactive material and radioactively contaminated equipment, including the necessary documentation;
(f) Contingency arrangements.

The decommissioning plan is based on a comprehensive radiological survey that identifies the location of radioactive material and the resulting exposure levels over the whole site, including peripheral areas used for activities such as transport, cleaning, repair and maintenance. The activity concentrations of radionuclides in environmental media such as water, soil and crops may have to be measured in areas surrounding the site to determine any contamination via airborne dust or entry into water courses. In addition, the survey needs to identify the radiological situation that will prevail during the decommissioning process itself as a result of the presence of radioactive material and contaminated equipment associated with decontamination and waste management activities.

ED_005285_00000684-00182

The decommissioning plan incorporates a detailed description of the facility, including a history of operations at the site compiled from official records and, where appopriate and feasible, from worker interviews. A detailed knowledge of these aspects helps to ensure not only that the radiological objectives of the decommissioning process are achieved but also that the scale and cost of the decommissioning process do not extend beyond what is really necessary. The following historical aspects are typically documented:

(a) All known industrial activities carried out on the site since the land was first occupied and developed;
(b) The process steps in which radioactive material was handled, the locations of the pipes, pumps, valves, tanks and storage areas involved, and the activity concentrations of the materials concerned;
(c) As full a description as possible of plant modifications and changes of ownership;
(d) Known leakages, spillages and movement of radioactive material, including transfers from storage for onward transport and transfers to impoundment areas.

The plan addressses each aspect of the decommissioning process in a level of detail commensurate with the degree of radiological hazard. As a plant undergoing decommissioning is likely to have been in operation for a long time, often with imperfect documentation and record keeping, it can prove difficult to anticipate exactly the location, nature and extent of radioactive deposits and soil contamination that have accumulated over the years of routine plant operation. For this and other reasons, the plan may have to be adjusted in response to unforeseen events as the decommissioning process proceeds.

The decommissioning plan quantifies the likely environmental impacts of the decommissioning process and the risks (both radiological and non-radiological) to workers engaged in the decommissioning work and to members of the public. In this regard, the following process materials are typical of those that have to be considered:

(a) Acids used in the various production processes;
(b) Ammonia;
(c) Hydrogen sulphide that might be present in sulphur storages;
(d) Scale, sludge residues and other materials in which radionuclides, such as radium, and heavy metals, such as arsenic, cadmium, chromium, lead, mercury and selenium, may accumulate.

ED_005285_00000684-00183

The adoption of postulated 'scenarios' can be useful in the planning of a decommissioning process, especially if there are major gaps in the known history of the plant. The scenario concept permits a 'what if' approach to the determination of hazards and risks that may be present at the site. It also facilitates future planning, including the consideration of possible future uses of the site and the likely exposure implications.

The compilation of the necessary risk assessments and other documentation is facilitated by having a comprehensive checklist of all types of equipment on the site, which may typically include:

(a) Reactor vessels, such as the attack tank and defluorination reactor;
(b) Storage tanks;
(c) Buffer tanks for spilled acids;
(d) Evaporators;
(e) Scrubbers;
(f) Pumps, valves and steel pipes, including rubber linings where used;
(g) Stainless steel frames, transport reels and rubber belts from belt filters;
(h) Seal tanks and table filters;
(i) Filter cloths and bag filters;
(j) Metal filter pans;
(k) Machine frames and other metal structures;
(l) Carbon stones and bricks from the reactor lining;
(m) Other bricks and ceramic floor tiles;
(n) Drains, gutters and drain wells.

The decommissioning plan sets out the training and safety procedures to be used, including the keeping of records of the training provided. The responsibility for radiation protection training is generally assigned to a designated radiation protection officer. The training of on-site personnel is of particular significance since few, if any, of these individuals are likely to have had prior experience of working in such an environment. The procedures are usually designed to ensure that work experience is formally documented in order to support a systematic learning process and to ensure that best practices developed during the course of the work are passed on to other decommissioning operations in the future.

11.1.2. Implementation of the decommissioning plan

The decommissioning process is carried out in accordance with the decommissioning plan. An operational survey may be carried out during the process in order to monitor progress and thereby identify any adjustments to the plan that may become necessary.

ED_005285_00000684-00184

Data relating to the dismantling and removal of equipment and the removal of residues, including radiological data such as gamma dose rates and surface contamination levels, are fully documented as the decommissioning process proceeds. The results of the radiological measurements provide the basis for determining how to deal with the materials and equipment and, in particular, whether they meet predetermined clearance criteria and can thus be released from the site. Where provided for in the decommissioning plan, some items of contaminated equipment may be decontaminated at the site in order to bring them into compliance with the clearance criteria. Further information on the management of scrap is given in Section 11.2.

11.1.3. Final report

A final report compiled at the end of the decommissioning process provides a comprehensive record of the work carried out and the results obtained. In this way, the report provides verification that the decommissioning process was carried out according to plan and that the objectives of the process were met. The final report can also assist in the planning and execution of similar decommissioning processes in the future and is of particular value in documenting the lessons learned as a result of having to deviate from the original decommissioning plan because of unforeseen events. It is common practice for a minimum retention period to be specified for the final report, typically 15–50 years, since it may be needed in the event of any future litigation. The content of the final report is illustrated in the following example from the decommissioning of a phosphoric acid plant in the Netherlands [66]:

(a) Historical information, documentation and references;
(b) A summary of the decommissioning project;
(c) A history of the organization and management of the project, including allocation of responsibilities and supervision, with comments on any variations from the initial plan;
(d) The applicable licences;
(e) The results of the preliminary inventory;
(f) An overview and description of the environmental monitoring programme and procedures, with any results or findings;
(g) An overview of the contaminated installation components that were identified;
(h) An overview of the methods applied for treating these components;
(i) The plan of action for each method;
(j) An inventory of the end point disposal of contaminated components;
(k) An overview of the release of equipment used;

ED_005285_00000684-00185

(l) A list of the tools and aids that were applied and released;
(m) A calculation of the doses received by workers and the public, records of which are to be retained for 35 years;
(n) An overview of the quantities and temporary storage of the radioactive waste produced;
(o) The transfer of radioactive material to third parties for the purpose of further processing;
(p) Remediation activities and procedures for the release of the site, with any necessary ongoing monitoring procedures.

11.1.4. Management of residues

The management of residues removed during the decommissioning of a phosphoric acid plant in Rotterdam, Netherlands, is described in Ref. [66]. The residues were categorized as either radioactive waste or chemical waste, depending on the radioactivity concentrations. These two categories of waste were managed in the following way:

(i) Radioactive waste: Radium rich scale and contaminated carbon and rubber having a total mass of 6.7 t were removed. The total ^{226}Ra activity was 7 GBq, implying an average activity concentration of more than 1000 Bq/g. The material was packed into 118 drums of 100 L capacity and transferred to the Centrale Organisatie voor Radioactief Afval (COVRA) along with the HEPA filters[26] used during decontamination operations. In order to meet the COVRA specification that the liquid content be less than 1%, the waste was dried by infrared heating before packing.
(ii) Chemical waste: Water used for high pressure water jet cleaning and having a total mass of 44 t was collected in 16 tank cars. Particles of radioactive scale were removed from the water by an industrial waste company but, because of the chemical impurities that remained dissolved within it, the water was classified as chemical waste and disposed of accordingly. The residual ^{226}Ra activity concentration was less than 1 Bq/L. A total of 750 t of phosphogypsum scale with a ^{226}Ra activity concentration of less than 1 Bq/g was also collected and classified as chemical waste.

[26] HEPA: High efficiency particulate air. A HEPA filter is a type of air filter that satisfies certain standards of efficiency, such as those set by the United States Department of Energy.

ED_005285_00000684-00186

FIG. 59. Typical lay down area for scrap.

11.2. MANAGEMENT OF SCRAP

Various contaminated scrap items are removed from wet process plants during periods of maintenance carried out as part of routine plant operation and during the eventual plant decommissioning process. Decontamination of these items can greatly facilitate the management of this scrap and opens up repair or recycling options that might not otherwise be available. In many cases, however, decontamination is not technically or economically feasible and the scrap, therefore, has to be managed as radioactive material. Many contaminated items take the form of metal components such as structural steel, gratings, pipes, valves, filter pans and vessels, for which refurbishment, repair or recycling by melting are often worthwhile options. If the metal is recycled by melting, the need for decontamination of the scrap metal can usually be avoided.

Generally, each site has designated 'lay down' areas for collecting and segregating scrap items and measuring their surface contamination levels (see Fig. 59). Items are segregated according to the route by which they will be managed. There are four main options for managing scrap at wet process plants:

ED_005285_00000684-00187

FIG. 60. Scrap designated for recovery of the metal content by melting.

(i) Off-site repair by a service company;
(ii) Off-site recovery of the metal by melting (see Fig. 60);
(iii) Off-site disposal in an industrial or hazardous waste landfill facility (see Fig. 61);
(iv) On-site disposal by burial, for instance in the phosphogypsum stack (see Fig. 62).

Procedures for the radiological monitoring of scrap leaving the facililty tend to vary. Some facilities routinely monitor individual items of scrap before they are loaded for transport. Other facilities rely on portal monitors located at the exit from the site to survey loaded trucks before departure.

11.2.1. Decontamination of scrap

There are significant variations in the types of contaminant and their radionuclide concentrations. Although vigorous washing is sometimes sufficient for removing surface contamination, techniques based on water jetting, chemical treatment or mechanical abrasion are usually necessary for removing more persistent contamination, such as the scale deposited in wet process plants.

ED_005285_00000684-00188

FIG. 61. Scrap designated for off-site disposal at a landfill facility.

FIG. 62. Scrap designated for on-site disposal by burial.

ED_005285_00000684-00189

Components that come into contact with acid are often protected by a rubber lining, which becomes progressively contaminated during plant operation. Rubber belts from belt filter systems also become contaminated. In Florida, USA, the contaminated surface layer of a long rubber belt from the belt filter system, including the accompanying transportation reel, was successfully abraded away using high pressure water jetting with a suitable combination of nozzles, pressure and water volume [53]. High pressure water was also used to decontaminate the rubber linings of the attack tank and the acid storage tank in a phosphoric acid plant, using remotely controlled jetting equipment and a suction system to remove and conserve the contaminated water. The mist generated during the decontamination operation was removed via a filter system. The water–air mixture was discharged using a demister and a high performance filter, thus minimizing any migration of radioactivity to the environment. Decontamination of rubber components is not always the chosen option, however. In the decommissioning of a phosphoric acid plant in the Netherlands [66], contaminated rubber was removed together with radium rich scale during dismantling of the plant. In this instance, the rubber was not decontaminated but, instead, was sent with the scale to a radioactive waste storage facility (see Section 11.1.4).

11.2.2. Management of contaminated scrap

Measurements were made on a large variety of scrap items at seven wet process facilities in Florida, USA, over the course of a year [275]. The total ^{238}U and ^{226}Ra activities contained within the items sampled were 106 and 322 MBq, respectively, and the total mass was 66 t. The mean activity concentrations were, thus, 1.6 Bq/g for ^{238}U and 4.9 Bq/g for ^{226}Ra. An analysis showed that more than half of the uranium activity resided in scrap destined for off-site disposal at landfill facilities (see Fig. 63), while 78% of the radium activity resided in scrap destined for burial at the site, usually in a phosphogypsum stack (see Fig. 64). Only a third of the items destined for off-site recycling or disposal exhibited gamma dose rates above background levels. For the four scrap management options (off-site repair, off-site metal recovery by melting, off-site disposal at a landfill facility and on-site disposal by burial), the situation could be summarized as follows:

(i) Only a few items were destined for off-site repair. These were decontaminated before leaving the site and were, therefore, excluded from the radiological analysis.

ED_005285_00000684-00190

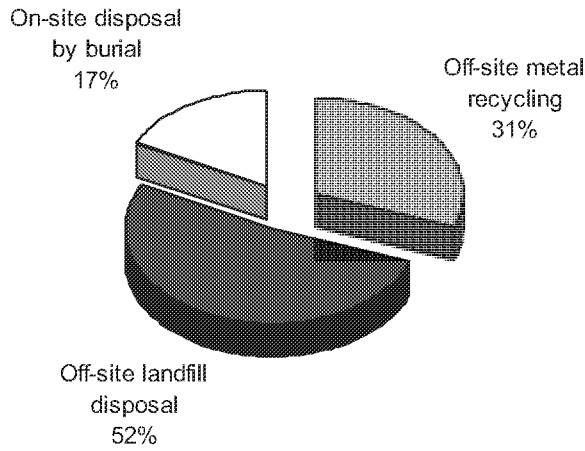

FIG. 63. Destination of ^{238}U activity in scrap arising from facilities in Florida, USA.

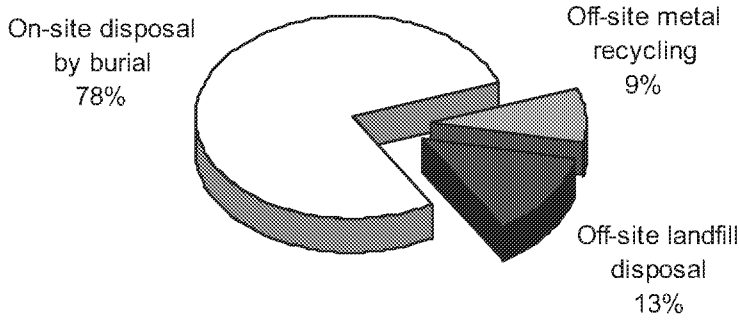

FIG. 64. Destination of ^{226}Ra activity in scrap arising from facilities in Florida, USA.

(ii) Most of the scrap metal (26 t) was sent to off-site metal recycling facilities. The mean activity concentrations of ^{238}U and ^{226}Ra were about 1.25 and 1.1 Bq/g, respectively.

(iii) The scrap sent for off-site disposal in landfill facilities (22 t) consisted predominantly of paper, cardboard and plastic. The mean activity concentrations of ^{238}U and ^{226}Ra were about 2.5 and 2 Bq/g, respectively.

(iv) The scrap retained for burial on-site consisted predominantly of process components such as filter cloths and fibreglass having little value for recycling. The mean activity concentrations of ^{238}U and ^{226}Ra were about 1 and 14 Bq/g, respectively.

ED_005285_00000684-00191

During the decommissioning of a phosphoric acid plant in Rotterdam, Netherlands [66], the following contaminated steel components were identified as suitable for recycling by melting:

(a) Parts of the tilting-pan filter;
(b) All steel pipes, including rubber linings;
(c) Vacuum seal tanks;
(d) Separators;
(e) Buffer tank.

The total activities of ^{226}Ra and ^{210}Pb contained within these items were 1.9 and 0.5 GBq, respectively, and the total mass was 62 t. The mean activity concentrations of ^{226}Ra and ^{210}Pb were, thus, about 30 and 8 Bq/g, respectively. The items were packed into seven closed IP-1 containers and transferred to a specialized melting facility. Objects that were too large, such as tanks, were cut into pieces before being packed.

11.3. OCCUPATIONAL EXPOSURE

The various decommissioning tasks are usually carried out according to standard operating procedures in order to ensure the effectiveness of the work and the safety of the workers involved. Health and safety precautions are incorporated into these procedures to ensure compliance with local OHS laws and regulations. Such precautions help to minimize the radiation exposure of workers. Similar considerations generally apply to the management of scrap.

Depending on the levels of exposure to radioactive material, decommissioning and scrap management work may have to be carried out in accordance with an appropriate radiation protection programme, as described in Ref. [4]. The requirements embodied in the radiation protection programme are likely to include the wearing of personal monitoring devices by selected workers to determine external exposure to gamma radiation and/or internal exposure from the inhalation of radionuclides in airborne dust. Both types of exposure can be significant because of the close proximity of workers to scale and other material with high radionuclide activity concentrations and because of the generation of airborne dust during welding, cutting, dismantling and decontamination activities. The potential for exposure is of particular concern when carrying out dismantling and decontamination work in confined areas such as tanks, especially when dry decontamination methods such as mechanical abrasion are used. During work of this nature, it is common for respiratory protection to be required as part of the standard OHS procedures and, in addition, exposure periods may

ED_005285_00000684-00192

have to be restricted. The use of high pressure water as an alternative to dry decontamination techniques, especially when, in confined areas, it is controlled remotely, as described in Ref. [53], is not only very effective in removing stubborn contamination but also considerably reduces the potential for exposure.

The decommissioning of a phosphoric acid plant at Rotterdam, Netherlands is described in Ref. [66]. The mean effective doses received by decommissioning workers over the duration of the decommissioning process are given in Table 37.

There is no published information on doses arising from the melting of scrap from wet process plants. However, a good estimate can be derived from the results of a detailed dose assessment conducted on an experimental melt of 38 t of uranium contaminated steel scrap from the South African gold mining industry [276]. The radioactivity levels in this scrap were similar to those reported in Ref. [275] for scrap from wet process facilities in Florida. The assessment of worker doses was based on the activity concentrations measured in the various process materials and in the air breathed by the workers. It was found that the inhalation of dust accounted for 96–100% of the dose. By making upward adjustments[27] to the South African results to account for differences in the activity concentrations of individual radionuclides in the uranium decay series, doses from the melting of metal scrap from wet process facilities were estimated and are given in Table 38. The mean annual committed effective dose for each category of worker is less than 1 mSv. The worker receiving the highest dose is the scrap processor. This worker operates the machinery for segmenting the scrap into sizes suitable for the furnace, a dusty operation involving exposure to airborne particles of contaminant during the full work period, assumed to be 2000 h/a. Should the contaminated scrap be mixed with uncontaminated scrap at the melting facility, some of the doses will, of course, be commensurately lower.

TABLE 37. DOSES RECEIVED BY WORKERS IN THE DECOMMISSIONING OF A PHOSPHORIC ACID PLANT [66]

Worker category	Mean effective dose (mSv)
Wet decontamination workers	1.2
Dry decontamination workers	<LLD[a]
Dismantling and construction workers and their assistants	<1.7
Supervisors	<LLD

[a] LLD: Lower limit of detection.

[27] These upward adjustments were 22% for contaminant particles, 69% for slag particles and 45% for flue gas particles.

ED_005285_00000684-00193

TABLE 38. DOSES EXPECTED TO BE RECEIVED BY WORKERS IN THE MELTING OF METAL SCRAP FROM WET PROCESS FACILITIES
(*derived from Refs [275, 276]*)

Worker	Mean annual committed effective dose (mSv)		
	Gamma radiation	Dust inhalation	Total
Scrap loader	0.0006	0.40	0.40
Truck driver	0.0002	Negligible	0.0002
Scrap processor	0.0001	0.99	0.99
Furnace operator	0.005	0.43	0.43
Casting worker	0.00003	0.30	0.30
Slag worker	0.02	0.52	0.55
Crane operator	0.0002	0.39	0.39

11.4. PUBLIC EXPOSURE

Since members of the public do not normally have access to sites on which decommissioning is being carried out, the potential for public exposure is very low. During the decommissioning of a phosphoric acid plant at Rotterdam, Netherlands [66], the annual effective dose received by the most highly exposed member of the public outside the facility was determined to be less than 0.4 μSv over the duration of the decommissioning process.

Doses received by members of the public as a result of the landfill disposal of scrap from wet process plants are likely to be insignificant. The mean radionuclide activity concentrations in the scrap are not expected to exceed 2–3 Bq/g and the possibility of any significant external and internal exposure is very small because the material is buried under controlled conditions designed to isolate the waste from the surrounding environment.

The doses received by members of the public as a result of exposure to steel recycled from wet process facilities have been estimated by considering the radioactivity content of uranium contaminated scrap originating from facilities in Florida, USA [275], together with the results of the dose assessment for steel recycled from similar scrap originating from mining activities in South Africa [276]. Allowances have been made for differences in radionuclide concentrations, principally the higher ^{226}Ra content in the scrap from Florida. In the original dose assessment carried out for mining scrap, the doses resulting from exposure of the public to gamma radiation from various steel products were calculated. It was found that the products giving rise to the highest doses were

ED_005285_00000684-00194

reinforcing bar for use in buildings and large foundry products such as components of large earthmoving equipment (the operators of which could be regarded as members of the public). The corresponding doses for steel recycled from wet process facilities are given in Table 39. The annual doses are all far below 1 mSv. In reality, it is unlikely that the steel used for product fabrication will originate entirely from contaminated scrap. Mixing with uncontaminated steel will take place either before or after the melting process. Consequently, the doses received by members of the public can be expected to be lower than those given in Table 39.

11.5. REGULATORY CONSIDERATIONS

The radionuclide concentrations in the materials encountered during the decommissioning of wet process plants and the management of scrap are frequently above 1 Bq/g and such activities clearly have to be considered for regulation as a practice. There is a potential for high occupational exposure to gamma radiation and radionuclides in airborne dust owing to the close proximity of workers to materials with elevated activity concentrations and the nature of the tasks involved in dismantling and decontamination operations. Moreover, residues designated as waste may need to be disposed of in a controlled manner in hazardous waste facilities. Nevertheless, annual doses received by decommissioning and scrap management workers appear to be below 1 mSv and doses received by members of the public are insignificant. It is important to bear in mind that standard procedures, particularly for decommissioning activities, generally incorporate health and safety precautions that are mandatory in terms of local OHS laws and regulations. While a formal radiation protection programme

TABLE 39. DOSES EXPECTED TO BE RECEIVED BY MEMBERS OF THE PUBLIC FROM EXPOSURE TO STEEL MADE FROM RECYCLED SCRAP DERIVED FROM WET PROCESS FACILITIES
(*derived from Refs [275, 276]*)

Material	Gamma dose rate (μSv/h)	Annual exposure period (h)	Annual effective dose (mSv)
Reinforcing bar used in walls	0.014	1500	0.02
Reinforcing bar used in floors and ceilings	0.025	1500	0.04
Large foundry products	0.057	2000	0.11

ED_005285_00000684-00195

may be desirable or necessary in some situations, it may not always be necessary to introduce additional regulatory controls specifically for purposes of radiation protection. The most appropariate regulatory option is likely to be a requirement for authorizaton in the form of a registration.

Residues arising from decommissioning and decontamination activities, while generally having elevated radionuclide activity concentrations of up to a few becquerels per gram, are, in most cases, likely to remain outside the scope of the Transport Regulations.

12. EXTRACTION OF URANIUM FROM PHOSPHORIC ACID

Phosphoric acid was once an important source of uranium [277], but subsequently, during the slump in uranium prices in the 1980s and 1990s, uranium extraction at phosphoric acid plants declined to the point where, from 1997 onwards, no further production is known to have taken place. Now, as a result of more favourable attitudes towards nuclear power and the depletion of uranium stockpiles, the price of uranium has recovered significantly and there is considerable interest once again in extracting uranium from phosphoric acid. Given that most of the uranium in phosphoric acid currently ends up in phosphate fertilizers, the extraction of uranium provides an added benefit, in that it reduces the potential for buildup of uranium in agricultural soils [278]. This section provides a summary of known best practices that may be adopted once uranium recovery from phosphoric acid is resumed in the near future.

Solvent extraction is currently regarded as the most highly proven and economic method of extracting uranium from phosphoric acid and will probably be the method of choice initially when production resumes. The ion exchange method is a promising alternative, but the technology is as yet unproven economically on a commercial scale. Continuing research into uranium recovery from phosphoric acid has resulted in a number of new, more powerful solvents as well as new ion exchange and membrane processes [279–281].

ED_005285_00000684-00196

12.1. THE SOLVENT EXTRACTION PROCESS

12.1.1. Process description

12.1.1.1. Main process

In general, all successful uranium recovery processes based on solvent extraction consist of five steps:

(i) Acid pretreatment;
(ii) Primary solvent extraction;
(iii) Raffinate post-treatment;
(iv) Secondary solvent extraction;
(v) Uranium refining.

There are also side stream operations such as residue treatment and strip acid preparation. The overall process is shown schematically in Fig. 65.

Acid pretreatment

Phosphoric acid is first cooled from 80°C to 30–50°C. This causes phosphogypsum impurities to come out of solution. These are usually removed by settling and returned to the phosphoric acid production process. Phosphogypsum also accumulates as scale in the heat exchangers and sometimes in the storage tanks. Activated carbon may be used to remove organic impurities from the phosphoric acid, after which the carbon is regenerated, typically with sodium hydroxide. The activated carbon absorbs radon which is not totally removed by the sodium hydroxide. Spent activated carbon is removed from the system as waste. If the uranium is to be extracted with a solvent that requires it to be in the U^{6+} state, the U^{4+} content of the phosphoric acid is oxidized to U^{6+} with air, oxygen, hydrogen peroxide, chlorine or nitric acid. If nitric acid is used, NO_x is emitted and usually has to be removed by a scrubber. If the uranium is to be extracted with a solvent that requires it to be in the U^{4+} state, the U^{6+} content of the phosphoric acid is reduced to U^{4+} by the addition of iron (scrap iron, iron balls or shredded iron) or ferrosilicon dust.

ED_005285_00000684-00197

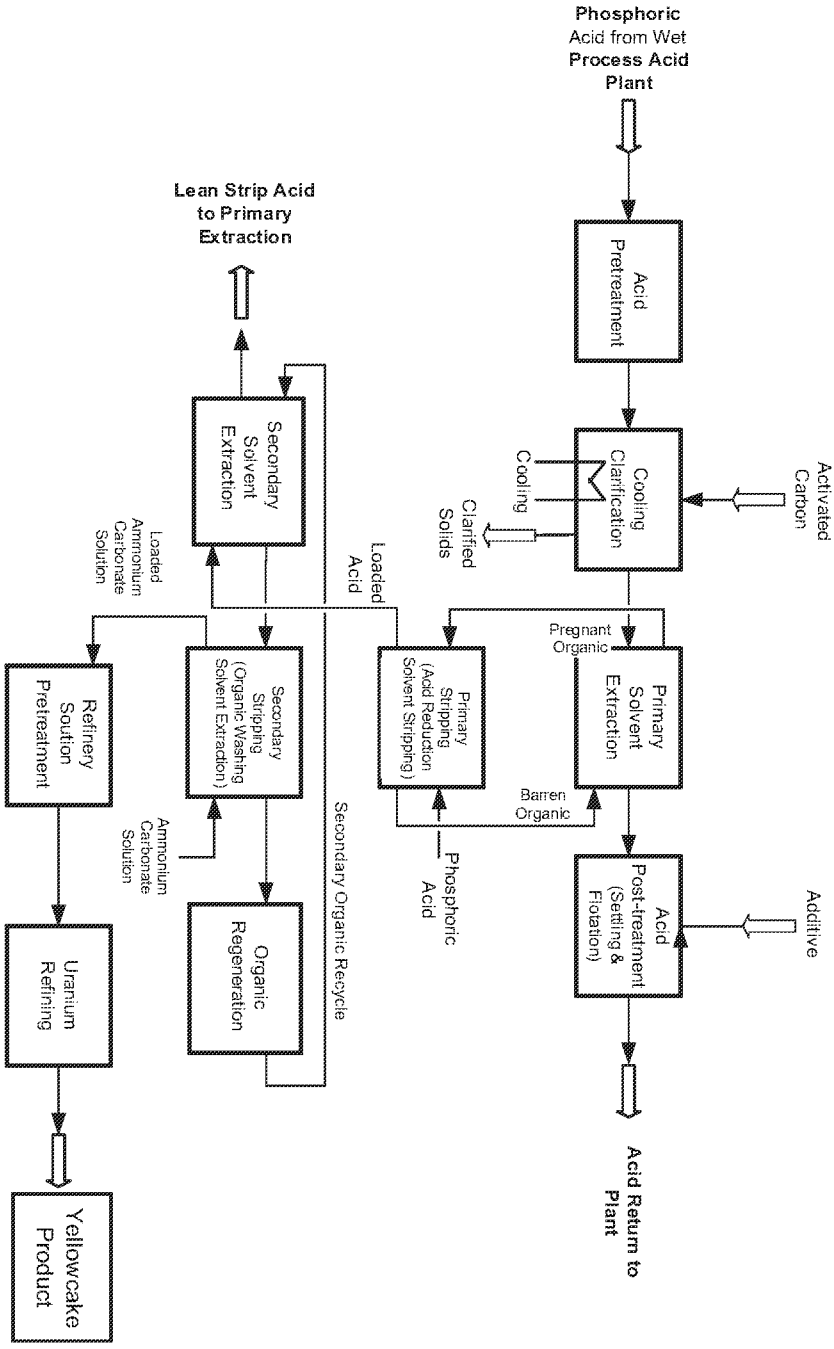

FIG. 65. Uranium recovery from phosphoric acid by solvent extraction.

ED_005285_00000684-00198

Primary solvent extraction

The solvent is a mixture of an extractant and a diluent (typically a petroleum compound). Prior to the suspension of uranium extraction operations in the late 1990s, the most commonly used extractant was a synergistic mixture of di-(2-ethylhexy) phosphoric acid (DEPA or D2EHPA) and tri-octylphosphine oxide (TOPO), which extracted uranium in the U^{6+} state. Octyl-phenylphosphoric acid (OPAP) and octyl-pyrophosphoric acid (OPPA), which extracted the uranium in the U^{4+} state, were also used. The pretreated phosphoric acid is contacted with the solvent in agitated mixer–settlers, in-line mixer–settlers or contacting columns. Typically, 3–6 stages of contact are used to remove 90–98% of the uranium from the acid. Depending on the solvent-to-acid ratio, the concentration of uranium attained in the solvent varies from 0.1 to 0.6 g/L, which is about 1–4 times the concentration in the original phosphoric acid. Stripping of the uranium from the solvent is accomplished by contacting the loaded solvent with phosphoric acid (27–50% P_2O_5). The strip acid is pretreated in one of two ways:

(i) If the uranium has been extracted in the U^{6+} state, iron is first added to the strip acid to convert its entire uranium content to the U^{4+} state. Since the addition of iron can cause rapid and significant iron phosphate scaling, all critical process lines are duplicated so that one can be washed out while the other is in operation. Sulphuric acid may also be added to minimize the precipitation of iron phosphate compounds.
(ii) If the uranium has been extracted in the U^{4+} state, an oxidizer is first added to the strip acid to convert its entire uranium content to the U^{6+} state. Traditionally, hydrogen peroxide has been used as an oxidizer, but oxygen, chlorine or nitric acid may also be used.

The concentration of uranium attained in the strip acid is typically 3–20 g/L.

Raffinate post-treatment

The phosphoric acid raffinate from the primary solvent extraction typically contains residual solvent at a concentration of about 100–500 ppm. Not only does this represent a loss of valuable solvent, but the diluent component can also cause damage to the rubber lined piping, evaporators and tanks that are downstream in the processing plant. The residual solvent is, therefore, removed in flotation cells. Using 5–10 such cells, the organic content of the raffinate can be reduced to less than 50 ppm.

ED_005285_00000684-00199

Secondary solvent extraction

The uranium in the strip acid from the primary solvent extraction is oxidized to the U^{6+} state using oxygen, hydrogen peroxide or nitric acid. The uranium is extracted using, as an extractant, a synergistic combination of DEPA and TOPO in several countercurrent stages employing 3–6 mixer–settlers. The uranium concentration attained in the solvent is about 15–30 g/L. The loaded solvent is washed with water to remove any entrained phosphoric acid. Using ammonium carbonate solution in two stripping stages, almost the entire uranium content is then stripped from the solvent. Since the stripped solvent has an affinity for ammonia, it is subjected to two stages of sulphuric acid washing to remove any ammonia before being recycled back to the front end of the process. Otherwise, the ammonia would react with the iron and phosphate in the oxidized feed acid and cause iron ammonium phosphate to be precipitated. The uranium concentration attained in the ammonium carbonate solution is generally about 15–30 g/L.

Uranium refining

The uranium in the ammonium carbonate solution is precipitated as ammonium diuranate ($(NH_4)_2U_2O_7$), ammonium uranyl tricarbonate ($(NH_4)_4UO_2(CO_3)_3$) or uranyl peroxide ($UO_4 \cdot nH_2O$). The precipitated uranium compound is known as 'yellowcake' because of its colour. The slurry is settled in a clarifier and extracted from the slurry feed either by centrifuging or filtration using pressure filters. The filtered cake is then sent to a dryer and optionally to a calciner. The calcined product contains more than 95% U_3O_8 together with small amounts of UO_2 and UO_3. It is usually drummed and sent by truck to a conversion plant where it is converted to UF_6 for enrichment. A typical truck shipment consists of about 18 t of yellowcake packaged in 40–50 drums, each containing 350–450 kg of product. Drums awaiting shipment are kept in a temporary storage area at the extraction plant accommodating up to 100–150 drums, thus providing sufficient capacity to cater for interruptions in trucking schedules. In areas of the plant where dry yellowcake is handled, the dust levels in the air are carefully controlled by ventilation, air scrubbers and HEPA filters.

12.1.1.2. Management of residues

The spent sodium hydroxide solution from the acid pretreatment step is sent to the acidic process water pond. The spent carbon may have a significant radioactivity content and its handling and disposal is, therefore, controlled

ED_005285_00000684-00200

appropriately. During the primary solvent extraction process, various residues are generated:

(a) An interfacial layer is formed, consisting of an emulsion of 1–5% solids in a similar volume of acid and solvent. The solids are insoluble in both acid and solvent. The layer is removed by suction pumping. While most of the acid and solvent can be removed from this residue using a pre-coat drum filter, chemical treatment or centrifuging, it is still one of the main causes of solvent loss. The formation of this residue is influenced by the effectiveness of the acid pretreatment step. The residue is disposed of either in the phosphogypsum stack or by burial on-site.

(b) Solid residues may be generated in the extraction mixer–settlers. If there is significant cooling of the acid, phosphogypsum and fluosilicates will precipitate. While some of these solids will end up in the interfacial layer, most will collect in the bottom of the settlers, which, therefore, have to be washed out periodically. About 20–40% of the content of the solids consists of acid. The solids, therefore, have a uranium concentration of up to 0.1 g/L. They are disposed of either in the phosphogypsum stack or by burial on-site.

(c) Solids are generated in the strip system when Fe^{2+} is oxidized to Fe^{3+} by the reduction of U^{6+}. This Fe^{3+} reacts with the phosphoric acid and any monovalent cations present to form iron phosphate compounded with ammonium, sodium or potassium. These solids generally end up at the bottom of the settler, but some may become entrained in the interfacial layer. The solids are removed periodically by washing out the solids with water or removing them manually. About 20–40% of the content of the solids consists of acid. The solids, therefore, have a uranium concentration of up to 8 g/L. They are disposed of either in the phosphogypsum stack or by burial on-site.

All the above disposal methods adopted in the past are unlikely to be practised in a future situation mainly owing to technological and regulatory improvements.

In the secondary solvent extraction, since the iron in the feed acid has been oxidized, there is significant precipitation of iron phosphate compounded with ammonium, sodium or potassium. These solids rapidly fill the settlers and must be removed as frequently as every few days. About 20–40% of the content of the solids consists of acid. The solids, therefore, have a uranium concentration of up to 8 g/L.

Throughout the extraction plant, there is a general tendency for uranium rich residues to accumulate on the surfaces of process equipment such as pipes, sumps and drains. Examples of such buildup are shown in Fig. 66.

ED_005285_00000684-00201

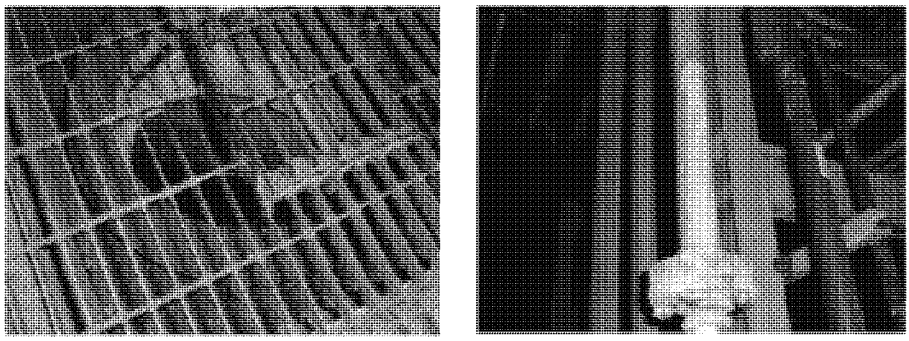

FIG. 66. Buildup of uranium rich residues within a solvent extraction plant.

12.1.2. Radionuclide activity concentrations

Pure uranium oxide (U_3O_8) contains ^{238}U and ^{234}U each at activity concentrations of 12 347 Bq/g and ^{235}U at an activity concentration of 568 Bq/g. It follows from the very purpose of the solvent extraction process, therefore, that many of the process materials and residues involved are likely to contain these uranium isotopes at very high activity concentrations. A summary of ^{238}U activity concentrations in the various process materials and residues associated with the solvent extraction process is given in Table 40 [282]. The dried yellowcake product has a ^{238}U activity concentration of the order of 10 000 Bq/g.

Radionuclides other than ^{238}U and ^{234}U, especially the remaining decay progeny of ^{238}U, are present in significant concentrations in materials associated with the acid pretreatment step. Here, residues consisting essentially of phosphogypsum and having a radionuclide composition similar to that of bulk phosphogypsum are precipitated as solid particles or deposited as scale. The spent activated carbon removed from the acid pretreatment step may have a significant radioactivity content resulting from the absorption of radon. From the point at which uranium is extracted from the phosphoric acid in the primary solvent extraction, the activity concentrations of radionuclides other than ^{238}U, ^{234}U and ^{235}U can be expected to be very low in relative terms. In absolute terms, however, such activity concentrations may still be significant. For instance, the activity concentration of ^{226}Ra in 65% grade yellowcake product is about 7.4 Bq/g.

ED_005285_00000684-00202

TABLE 40. URANIUM-238 ACTIVITY CONCENTRATIONS IN PROCESS MATERIALS AND RESIDUES ASSOCIATED WITH THE SOLVENT EXTRACTION PROCESS

Extraction process	Activity concentration (Bq/L)[a]
Primary solvent extraction:	
Loaded solvent	1300–7900
Loaded strip acid	40 000–260 000
Interfacial residue and, where used, filter pre-coat	Similar to or less than that in the incoming phosphoric acid[b]
Solids from extraction mixer–settlers	Up to 1300
Solids from strip system	Up to 100 000
Secondary solvent extraction:	
Loaded solvent	190 000–380 000
Loaded ammonium carbonate solution	190 000–380 000
Solids from mixer–settlers	Up to 100 000

[a] For solids, the activity concentration is given as becquerels per kilogram.
[b] For phosphoric acid produced from sedimentary rock in Florida, USA, the range of U-238 concentrations is 3500–5200 Bq/L.

12.1.3. Occupational exposure

12.1.3.1. Exposure pathways and exposure levels

Solvent extraction of uranium from phosphoric acid is not a labour intensive process. The number of workers employed per shift in an extraction plant is between 4 and 20, or even fewer in a plant with computerized process control systems. The potential for external gamma exposure is moderate because the workers tend to spend only short periods in areas of high dose rates and the concentrations of gamma emitting radionuclides such as radium and its progeny are relatively low. Furthermore, exposures to the yellowcake product are moderated by the shielding provided by centrifuge enclosures and the drums within which the product is packaged. Nevertheless, exposure to drums of yellowcake can become significant in the temporary storage area because of the number of drums stored. The dose rate on contact with a drum of yellowcake may reach 100 μSv/h, depending on the concentrations of ^{238}U decay progeny. The main potential exposure pathway is the inhalation of airborne dust, particularly for workers engaged in yellowcake drying and packaging activities. Ingestion of

ED_005285_00000684-00203

uranium as a result of contamination of skin and clothing is a concern, but more because of the chemical toxicity of uranium rather than its radiological effects.

12.1.3.2. Monitoring techniques for workers

External exposure is monitored using personal dosimeters (LiF TLDs or Al_2O_3:C OSLDs) worn on the chest and extremity dosimeters worn on the fingers. Monitoring of dust activity concentrations in the air, particularly in areas where yellowcake is handled, is carried out using stationary air sampling or personal air sampling. Workers who routinely handle yellowcake may be monitored using urine analysis, typically on a quarterly basis, to confirm that intakes of uranium continue to be low. The external surfaces of drums of yellowcake are checked with surface contamination monitors before shipping.

12.1.3.3. Effective dose

Although published data on annual effective doses received by workers in past operations are not available, reports suggest that such doses are usually not more than a few millisieverts and well below the occupational dose limit of 20 mSv.

12.1.3.4. Measures to reduce doses

Spillages can lead to workers being unexpectedly exposed to material with high activity concentrations. For instance, if the loaded solvent from secondary solvent extraction is spilled on the floor area surrounding the process equipment (typically a concrete pad), evaporation of the solvent can cause the uranium concentration to rise far above the normal level of 15–30 g/L. If all the solvent evaporates, the uranium content of the residue can be as high as 30%. At this level, the activity concentrations of ^{238}U and ^{234}U will each be almost 4×10^6 Bq/L. Such exposures can be avoided if care is taken to prevent such spillages and, if they do occur, to keep the area around the solvent extraction system flushed with water to prevent the buildup of high activity residues.

The use of thick, concrete walls for the construction of the yellowcake storage area has been found to provide effective shielding from the high dose rates in that area. In this way, the external exposure of workers on the other side of the wall is reduced to levels where no special precautions need be taken against external exposure.

Other measures that are known to be effective in reducing occupational exposure in solvent extraction plants include:

ED_005285_00000684-00204

(a) The adoption and enforcement of procedures to ensure that equipment, especially air filtration equipment, is properly maintained;
(b) The adoption and enforcement of good, general housekeeping measures, including the removal of settled dust and of sediments that build up on equipment such as structural steel, pipes and drains (see Fig. 66), so that the levels of contamination in the plant remain under adequate control;
(c) The use of smooth, hard finishes, such as epoxy coatings on floors and walls, to improve the effectiveness of routine cleaning and to facilitiate the cleanup of spillages;
(d) The provision of suitable bounded areas (berms and sumps) around process equipment having the greatest potential for major spillage;
(e) Maintenance of high levels of worker training and awareness;
(f) The provision of protective clothing, footwear barriers and decontamination facilities;
(g) The provision of respiratory protective equipment for certain tasks such as the changing of air filters, where engineering controls and administrative measures alone are not sufficient to control worker exposures adequately;
(h) Restrictions on eating, drinking and smoking in certain areas;
(i) Ensuring the effectiveness of administrative controls, such as the designation of controlled and supervised areas and the maintenance of strict access control.

12.1.4. Public exposure

There are normally no significant exposure pathways to members of the public from solvent extraction facilities. Liquid effluents are not discharged without adequate treatment. Gaseous discharges from ventilation systems are controlled by scrubbers and HEPA filters. Most of the radioactive residues generated by the process are recycled back to the process or, where disposed of as waste, are buried on the site, either in the phosphogypsum stack or nearby. The traditional practice of on-site burial in or next to the phosphogypsum stack may have to change in future to meet the changing regulatory requirements in respect of waste management practices. If future phosphogypsum stacks are no longer to be treated as disposal sites but, instead, as temporary holding areas pending future use of the phosphogypsum, then radioactive waste from the solvent extraction process will have to be kept separate and transported off the site to a suitable radioactive waste disposal facility.

ED_005285_00000684-00205

12.2. OTHER PROCESSES FOR THE EXTRACTION OF URANIUM

12.2.1. Ion exchange extraction

Ion exchange is a potentially attractive process for uranium recovery from phosphoric acid, presenting both challenges and opportunities [283, 284]. Compared with the solvent extraction process, the ion exchange process requires fewer pretreatment and post-treatment steps and offers potential economic advantages. The technology is, as yet, unproven on a commercial scale, but pilot testing, which is well advanced, has indicated several provisional but nonetheless positive conclusions. Compared with the solvent extraction process, the ion exchange process:

(a) Is potentially advantageous from an environmental point of view, because it avoids the generation of (radioactive) solvent extraction residue;
(b) Is better suited for feed phosphoric acid with uranium concentrations of less than 300 mg/L;
(c) Tends to have lower capital and operating costs for low uranium concentrations in the feed acid;
(d) May be tolerant of higher process temperatures (up to 80°C), a potentially significant cost saving as compared with solvent extraction, which may require the acid feed to be reheated on return to the phosphoric acid plant;
(e) May be more tolerant of organic acids in the feed acid;
(f) Eliminates the requirement for post-treatment of phosphoric acid raffinate;
(g) When used as a fluidized bed system, is tolerant of solids in the feed acid, implying a reduced need for clarification in pretreatment steps.

12.2.2. Solid membrane extraction

Uranium can be removed directly from phosphoric acid in a single step using porous membranes. This process yields very pure phosphoric acid and efficient uranium recovery in a single stage. However, the recovered uranium is a supersaturated concentrate containing chemical impurities that have also been removed from the acid. These impurities must be separated and removed as a waste stream. The membranes themselves are likely to become repeatedly clogged and quickly worn out, necessitating vigilant, well-trained operators and an effective, well-supervised maintenance and renewal regime. The disposal of the impurities removed from the process and of the spent membranes may have radiological implications.

ED_005285_00000684-00206

12.2.3. Liquid membrane extraction

Liquid membrane extraction is based on an emulsion containing both a liquid membrane extractant and a stripping solution. The extractant could be one of those used for solvent extraction, such as OPAP or DEPA–TOPO. Uranium is removed from the surfactant-stabilized membrane in an aqueous stripping phase. Very high uranium recoveries are achieved. A coalescent breaks down the uranium laden emulsion for recovery.

12.3. REGULATORY CONSIDERATIONS

Owing to the very high activity concentrations of uranium isotopes and other radionuclides in the yellowcake product and most of the intermediate process materials and residues, the extraction of uranium from phosphoric acid, regardless of the process used, is unquestionably regulated as a practice. Experience with extraction plants operated in the past has shown that workers received committed effective doses that under normal circumstances did not exceed a few millisieverts per year. There are no significant exposure pathways to members of the public. However, a formal (and effective) radiation protection programme, which includes a comprehensive monitoring programme, is the only way to ensure that workers do not receive much higher doses. Further details on the content of such a programme are given in Ref. [4]. In addition, the disposal of the radioactive waste generated by the solvent extraction process has to be carried out under controlled conditions. Consequently, the most appropriate regulatory option is a requirement for an authorization in the form of a registration or licence, the choice depending very much on the national approach. In many countries, the fact that uranium extraction is part of the front end of the nuclear fuel cycle necessitates that the authorization be in the form of a licence.

Owing to the high activity concentrations, the transport of yellowcake off the site and of any radioactive waste destined for off-site disposal falls firmly within the scope of the Transport Regulations.

ED_005285_00000684-00207

13. PRODUCTION OF ELEMENTAL PHOSPHORUS BY THERMAL PROCESSING OF PHOSPHATE ROCK

Thermal processing of phosphate rock to produce elemental phosphorus using the so-called electric furnace method was developed in the USA from 1933 onwards by the Tennessee Valley Authority (TVA) and was widely used to produce phosphoric acid during the period 1934–1977 in countries such as Canada, China, Germany, Kazakhstan, Netherlands and the USA [45].

In the past, phosphate rock was also thermally processed using the so-called blast furnace method. This process, which was originally used during the period 1929–1939 [45], had the advantage of being able to make use of low grade phosphate rock, provided that the main impurity was silica, with both iron oxide and alumina causing less difficulty in production than was the case for the wet process. In the late 1940s, the TVA investigated further improvements to the blast furnace process [285]. An attempt to revive the process in the late 1960s foundered on the high cost of coke [286], leaving the electric furnace method as the only method in use.

The thermal process has been used mainly for the production of high purity ('furnace grade') phosphoric acid, which is a constituent of products such as industrial chemicals, insecticides, detergents, food additives and feeds. Although the process still plays an important role in phosphoric acid production worldwide, its use has declined from past levels. At the end of 2001, one of the last two elemental phosphorus production facilities in the USA was shut down, leaving only one facility (at Soda Springs, Idaho) in operation in that country. Another facility continues to operate at Vlissingen, Netherlands. More recently, significant increases in the price of sulphur (a source of sulphuric acid used extensively in the wet process) have created conditions for a resurgence of interest in the thermal process. In China, for example, the nature of energy production, largely based on hydroelectric generation at a local level, has supplied inexpensive power to phosphoric acid plants for many decades. Since thermal acid production is very energy intensive, this advantage has been decisive in retaining a large thermal phosphorus production capacity in China, despite the fact that more recent joint ventures with Western companies have now brought wet acid production, as well as MAP and DAP production, to China on a large scale.

ED_005285_00000684-00208

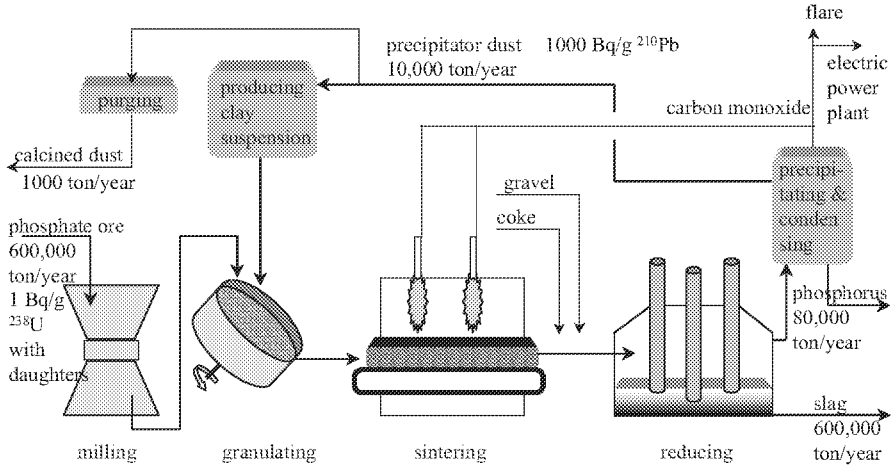

FIG. 67. Schematic representation of the thermal phosphorus process used by TIBV (from Ref. [287]). The numerical values are representative only and may vary considerably, depending on the characteristics of the phosphate rock feedstock.

13.1. PROCESS DESCRIPTION

13.1.1. Main process

Sintered pellets produced from finely powdered phosphate rock are fed into an electric arc furnace together with gravel and coke. The reduction of the phosphate produces elemental phosphorus along with calcium silicate slag, carbon monoxide and calcium fluoride according to the following chemical reaction:

$$2Ca_{10}F_2(PO_4)_6 + 30C + 12SiO_2 \rightarrow 3P_4 + 30CO + 6(3CaO{\cdot}2SiO_2) + 2CaF_2$$

A schematic representation of the process used at a plant operated by Thermphos International BV (TIBV) in the Netherlands (formerly part of Hoechst Holland NV) is shown in Fig. 67. This plant produces 80 000 t of elemental phosphorus, 600 000 t of calcium silicate slag and 4000 t of ferrophosphorus annually. The phosphate ore is first milled to a fine powder, which is then fed to a rotating granulator disc together with a binder consisting of a suspension of clay in water together with recycled precipitator dust. The rotation of the disc results in the formation of pellets. The pellets are fed to the front end of a slowly rotating sintering grate. They pass through a drying zone maintained at a temperature of up to 300°C and are then sintered to hard spheres

ED_005285_00000684-00209

under two large burners at a temperature of about 800°C. The pellets then pass through a cooling zone. The heat released from the pellets is directed to the drying zone. The pellets are then conveyed to an intermediate storage facility where they are stored in large silos in readiness for feeding to the electric furnaces. In sintering plants operating in other countries, the sintering process may differ in that the phosphate rock is not milled and a higher sintering temperature is used.

The sintered phosphate feedstock material is fed into an electric arc furnace together with the gravel and coke. The chemical reaction in which phosphate ore is reduced to elemental phosphorus takes place at temperatures exceeding 1500°C. The elemental phosphorus leaves the furnace as a gas, together with the carbon monoxide formed during the reaction. After removal of entrained dust, the gases are cooled, causing the phosphorus to condense to a stream of liquid phosphorus.

Production of phosphoric acid from elemental phosphorus is reasonably straightforward. Liquid elemental phosphorus is burned in air and the resulting P_2O_5 is then hydrated to create furnace grade phosphoric acid. The overall reaction may be characterized as:

$$P_4 + 5O_2 + 6H_2O \rightarrow 4H_3PO_4$$

13.1.2. Management of residues

The calcium silicate slag produced during the process flows continuously from the furnace. Trace amounts of iron are also reduced in the furnace. These form a separate slag, ferrophosphorus, containing approximately 75% iron, 25% phosphorus and small amounts of other metals. The calcium silicate slag is a stone-like by-product with applications as a construction material for roads, dykes and possibly dwellings. It is a good substitute for gravel, the mining of which can have undesirable environmental consequences through the formation of gravel pits. When used in a road bed, especially when used together with steel slag, its angular structure imparts greater resistance to subsidence.

At the high temperatures prevailing in the furnace, volatile inorganic substances, metals and radionuclides evaporate and condense on dust particles. The dust is trapped in electrostatic precipitators. In the TIBV plant, about 10 000 t of precipitator dust is produced annually, most of which is recycled back to the sintering plant. It is fed to slurry tanks where it is mixed with water and pumped to the 'slurry station' for reuse as a component of the binding suspension used for pelletizing the phosphate powder. When the volatile inorganic substances, metals and radionuclides contained within the precipitator dust reach the furnace for the second time, they evaporate again. In this way, these substances become enriched

ED_005285_00000684-00210

in the so-called precipitator dust cycle. High concentrations of volatile inorganic matter and metals cause instability in the operation of the furnaces. To control the concentration, 500–1000 t of precipitator dust are purged from the system annually by diverting the dust stream to a purge unit housed in the slurry station. The purge unit consists of a high pressure filter and a rotating calcining kiln where the pressed, lumped precipitator dust is calcined at temperatures of 400–500°C before being removed as waste. The recycling of precipitator dust in this manner reduces the amount of solid waste requiring disposal, but increases the emissions of radionuclides to the atmosphere. Modifications to the precipitator dust recycling process have since been made to reduce these radionuclide emissions [288]. In plants in other countries, it has been more common in the past for the precipitator dust to be disposed of rather than recycled back to the process.

Calcined precipitator dust produced in past operations at the TIBV plant at a rate of 500–1000 t/a is stored on-site. Calcined dust from current operations is being stored at the centralized COVRA radioactive waste storage facility. Storage allows the ^{210}Pb to decay sufficiently for the material to be disposed of in a landfill facility after immobilization in cement [289]. For instance, after 150 years, the ^{210}Pb activity concentration will have fallen from 1000 Bq/g to 10 Bq/g. The material at COVRA is stored in containers fitted with plastic linings and stacked in a purpose-built storage building. To avoid taking up excessive space in the storage building, immobilization in cement will be carried out only after the decay storage period has elapsed.

13.2. RADIONUCLIDE ACTIVITY CONCENTRATIONS

During the sintering process, ^{210}Po, which has a half-life of 138 d, volatilizes and escapes from the feedstock material. It passes through the scrubbers that wash the sinter gases and is emitted to the atmosphere. Most of the ^{210}Pb, which is less volatile than ^{210}Po, remains in the sintered feedstock.

In the furnace, the radionuclides above ^{222}Rn in the ^{238}U decay chain (see Appendix I) remain in the melt and become part of the calcium silicate slag. Of the radionuclides escaping from the melt, the two most important in terms of gamma dose (^{214}Pb and ^{214}Bi) grow back into the slag after about two weeks. Since approximately one tonne of slag is formed per tonne of phosphate rock feedstock, the activity concentrations of ^{238}U, ^{214}Pb and ^{214}Bi in the slag are similar to those in the feedstock (about 1 Bq/g). The ^{222}Rn escaping from the melt leaves the furnace along with the carbon monoxide. Only those radionuclides below ^{222}Rn in the ^{238}U decay chain end up in the precipitator dust. Consequently, the ^{238}U activity concentration in the precipitator dust is low, with a maximum

ED_005285_00000684-00211

value of about 1 Bq/g. The behaviour of the radionuclides in the precipitator dust can be summarized as follows:

(a) The short lived progeny of radon (^{218}Po, ^{214}Pb, ^{214}Bi and ^{214}Po) decay within a few hours.
(b) In the TIBV process, the relatively long lived ^{210}Pb (half-life of 22 a) builds up in the precipitator dust during the recycling process to an activity concentration of about 1000 Bq/g, representing a thousandfold enrichment of this radionuclide. Owing to the loss of ^{210}Po during the sintering of the pellets, the activity concentration of ^{210}Po in the precipitator dust is initially only about 60 Bq/g, considerably lower than the activity concentration of ^{210}Pb. The half-lives of ^{210}Bi and ^{210}Po (progeny of ^{210}Pb) are 5 and 138 d, respectively, and after about four half-life periods, these progeny are again present in the precipitator dust at nearly the same activity concentration as that of the parent radionuclide, ^{210}Pb.

Very little radioactivity migrates to the elemental phosphorus product or to the ferrophosphorus slag. The phosphorus contains ^{226}Ra at an activity concentration of 0.03 Bq/g, while the ferrophosphorus contains ^{238}U series radionuclides each at an activity concentration of 0.03 Bq/g.

13.3. OCCUPATIONAL EXPOSURE

13.3.1. Exposure pathways

Phosphorus plant workers are exposed to airborne dust originating from the phosphate rock, but since the activity concentrations are low, the exposure levels are not significant. In the case of the TIBV plant, where the recycling of precipitator dust is carried out, the activity concentrations of ^{210}Pb and ^{210}Po in the dust are approximately 1000 times higher than in the phosphate rock. This then becomes the main source of exposure of plant workers.

13.3.2. Exposure of plant workers

13.3.2.1. Monitoring techniques

This section describes the monitoring techniques used for workers at the TIBV plant. To determine the intakes of radionuclides by workers, TIBV makes measurements using personal air sampling equipment comprising a battery powered air pump connected by a flexible tube to a filter located in a filter holder [287].

ED_005285_00000684-00212

During the period 1998–2003, TIBV sampled the inhalable dust fraction using an IOM sampling cassette (see Fig. 3). Since 2004, a thoracic sampler has been used instead (see Fig. 4) [290], in order to minimize dose assessment errors (see Section 3.3.2). The equipment is carried by the worker in such a way that a continuous sample of the air surrounding the worker passes through the filter. The dust is separated from the air and collected on the filter. The worker carries the personal air sampler for the working shift of 8 h.

Alpha and beta activities on the filter are measured using a proportional counter capable of discriminating between alpha and beta radiations. The achievement of the necessary statistical accuracy requires a counting time of 5 d, necessitating the use of a 10 channel counter. The activity of ^{210}Pb on the filter cannot be measured directly because the beta emission from this radionuclide is very weak. It is determined, instead, from the beta emission from ^{210}Bi, which has a maximum energy of 1.16 MeV. To ensure that ^{210}Bi reaches radioactive equilibrium with its parent ^{210}Pb, it is necessary to retain the filter for three weeks before carrying out the measurement. The alpha emission from ^{210}Po has an energy of 5.3 MeV, allowing the activity of this radionuclide to be measured directly.

The worker's radionuclide intake is determined from the count rates obtained from the filter, the rate of air flow through the filter, the worker's breathing rate (usually taken as 1.2 m^3/h) and the exposure time (typically 8 h). For those work functions associated with the highest intakes and a wide confidence interval, the frequency of measurement is increased in order to narrow the confidence interval and thus obtain a more accurate dose assessment.

Dissolution tests conducted at TIBV indicate that the slowest lung absorption type (S) is the most appropriate for dose calculation purposes. Assuming this lung absorption type, the committed effective doses per unit intake of radionuclide activity have been determined for ^{210}Pb and ^{210}Po as functions of AMAD and GSD. The results are shown in Figs 68 and 69. Since, for AMADs of 0.5–5 μm, the dose coefficients remain within a relatively small range, TIBV uses dose coefficients representative of this range, namely 5.8 and 4.2 μSv/Bq for ^{210}Pb and ^{210}Po, respectively.

TIBV has carried out a dust characterization using a cascade impactor to determine the activity distribution as a function of particle size. The results indicate that there is considerable activity associated with particles having an AMAD greater than 0.5–5 μm, especially where workers produce the dust themselves during cleaning work. Under such circumstances, a considerable part of the activity intake is believed to originate from dust particles with AMADs of 5–10 μm and greater. The implication for a worker involved in cleaning work with freshly produced airborne dust is that the dose determined on the basis of an AMAD of 0.5–5 μm will be overestimated because of the lower dose coefficients associated with these larger particles.

ED_005285_00000684-00214

13.3.2.2. Effective dose

To simplify the dose calculation, it can be assumed that all the inhaled alpha activity originates from ^{210}Po and all the inhaled beta activity originates from ^{210}Pb. The results of the dose assessments carried out since 2004 at the TIBV plant using thoracic sampling devices [288] are given in Table 41. The average

TABLE 41. DOSES RECEIVED BY WORKERS AT THE TIBV THERMAL PHOSPHORUS PLANT [288]

Worker	Annual committed effective dose (mSv)			Contribution of Pb-210 to dose (%)[a]	Average dose for 1998–2003 assessed using 'inhalable dust' samplers (mSv) (for comparison)
	Average	Standard deviation	90% confidence interval		
Sintering plant:					
Indoor operator	0.67	0.57	0.48–0.86	64	1.63
Granulating operator	0.47	0.31	0.31–0.63	52	1.03
Slurry operator	0.48	0.42	0.28–0.68	60	0.66
Cleaning operator	0.74	0.45	0.61–0.87	53	2.17
Overall	0.57	0.39	0.51–0.63	54	1.31
Phosphorus plant:					
Filtration	0.23	0.07	0.18–0.28	63	0.39
Condensation	0.28	0.12	0.21–0.35	58	0.52
Electrode welder	0.33	0.16	0.25–0.41	66	0.63
Daytime operator	0.29	0.12	0.19–0.39	72	0.95
Furnace feed	0.44	0.42	0.29–0.59	67	0.72
Slag operator	0.34	0.21	0.17–0.51	59	0.56
Slurry operator	0.41	0.23	0.32–0.50	70	0.64
Cleaning operator	0.48	0.27	0.36–0.60	72	1.59
Overall	0.33	0.19	0.30–0.36	70	0.90
Supervisors	0.26	0.17	0.22–0.30	65[b], 73[c]	0.65[b], 1.37[c]
Overall (both plants)	0.43	0.35	0.38–0.48	61	1.09

[a] Obtained from 1998–2003 measurements.
[b] Shift supervisor.
[c] Assistant supervisor.

ED_005285_00000684-00215

annual effective doses are well below 1 mSv throughout the plant, with an overall average of 0.43 mSv. The highest dose (upper 90% confidence limit) is 0.87 mSv, received by the cleaning operator in the sintering plant. The contribution of ^{210}Pb to the total dose is about 50–70%, with ^{210}Po accounting for the rest. Also shown in Table 41 are the average doses assessed during 1998–2003 by sampling the inhalable fraction using IOM cassettes. A comparison of the two sets of results gives an indication of the amount by which the dose was overestimated in the past as a result of using an AMAD range of 0.5–5 μm, when a substantial fraction of the activity was associated with particles with AMADs greater than 5 μm (see Section 13.3.2.1). Overall, the doses were overestimated by a factor of 2.5.

The variation in assessed doses is large because work activities can differ from day to day and the concentrations of radionuclides in the air fluctuate widely. In earlier monitoring programmes at TIBV, it was found that the dose assessed over the standard one day measuring period varied from zero up to five times the average daily value [287]. The achievement of small confidence intervals for every work function would require a prohibitively large number of measurements being taken. For all the functions together within one plant, however, the confidence interval was considered acceptable.

The dose variations depend on the process (which is predetermined) and on the specific working conditions and work practices that affect the exposure of the worker (which are less easy to predict). The following examples were found at the TIBV plant:

(a) Two workers carried out the same cleaning work on the same floor. After the work was completed, the first worker was covered in dust while the other was clean. The first worker used a broom for certain cleaning activities whereas the other used only the prescribed vacuum cleaner. Both operators inhaled the same 'background' air. The committed effective dose assessed for the first worker was 0.02 mSv over just that one working shift, while the dose for the second worker was almost zero. This demonstrated that the background air was essentially free of radionuclides and that the dose received was influenced almost entirely by the working activities and especially the way in which they were carried out.

(b) Some workers, such as electrode welders, work in an environment in which there is no contamination of surrounding surfaces and, thus, no possibility of receiving a dose from the resuspension of dust. It was demonstrated, however, that the air in such a workplace was contaminated by the activities necessary to remove slag (into slag beds situated immediately next to the furnace building) and ferrophosphorus from the furnace.

(c) Large surface areas of some workplaces were contaminated by dry precipitator dust containing ^{210}Pb and its progeny at an activity

ED_005285_00000684-00216

concentration of 1000 Bq/g. This contamination did not always lead to a dose; daily monitoring of workers in these areas often gave an assessed dose of zero. Simply walking through the contaminated area did not necessarily lead to inhalation of the dust because of the distance between the resuspension point (the feet) and the inhalation point (the nose and mouth). However, if work had been carried out at a fixed location in that area, the resuspended particles could have been inhaled and would have led to an effective dose of 0.04 mSv committed over the course of just one working shift. On one occasion, a compressed air hose broke loose from its connection and dust was blown from the floor over a period of several minutes. The exposure measured over the full working shift corresponded to a dose of 0.12 mSv committed in just that one shift.

(d) Measurements showed that it was possible to create concentrations of dust that, if inhaled, would result in an effective dose of up to 1 mSv being committed in a 1 h period if highly contaminated parts of an installation were subjected to various mechanical procedures to remove surface contamination, thereby causing the resuspension of contaminant particles into the air. Contamination levels of several hundred becquerels per square centimetre have been measured on internal surfaces of process equipment. Under normal circumstances, workers are not exposed to these high levels of contamination but, when the installation is opened for maintenance or repair, measures have to be taken to prevent large inhalation doses from being received.

13.3.2.3. Measures to reduce doses

At the TIBV plant, by taking more measurements at the same time at different places in a working area and comparing them with earlier measurements, taking the working and process conditions into account, it has been possible to determine the pathways by which the radionuclides liberated from the process reached the workers involved. This has allowed dose reduction measures to be identified. An aerosol monitor giving 3 h average measurements has been used to study the fluctuations in concentration of alpha and beta emitting radionuclides in air. With this device, it is possible to identify sources of dust responsible for enhancing air concentrations.

Measures taken at the TIBV plant to reduce doses from inhalation of dust include the following:

(a) Conduct of large scale continuous cleaning operations;
(b) Renewal and coating of floor surfaces to enable them to be decontaminated more easily;

ED_005285_00000684-00217

FIG. 70. Half-mask respirator.

(c) Prevention of contamination by the installation of new measuring instruments and automation to monitor and control the process;
(d) Improved ventilation at the ferrophosphorus outlet of the furnaces;
(e) Relocation of the slag beds away from the furnace building;
(f) Installation of central vacuum cleaning systems to avoid the need to open and empty mobile vacuum cleaners.

In addition, safety procedures attempt to minimize the possibility of higher exposures. If a vessel, sintering oven or furnace has to be opened and workers have to enter, the surface contamination levels are measured first. If the contamination level is less than 0.25 Bq/cm^2, workers may enter without protective equipment. If the contamination level is 0.25–10 Bq/cm^2, a half-mask respirator with an assigned protection factor of 20 is worn (see Fig. 70). If the contamination level exceeds 10 Bq/cm^2, a full face mask respirator with remote air supply is worn (see Fig. 71). These criteria have been derived conservatively from the results of measurement programmes, but are intended to apply only to inspection work or to other activities that do not produce significant amounts of dust. For activities producing dust, a full face mask respirator with remote air supply is worn, irrespective of the surface contamination level.

FIG. 71. Full face mask respirator with remote air supply.

13.4. PUBLIC EXPOSURE

13.4.1. Discharges from the plant

13.4.1.1. Inhalation exposure

During thermal phosphorus production, the radionuclides above ^{222}Rn in the ^{238}U decay series remain in the slag and are, therefore, not emitted to the atmosphere. Radon escapes from the melt and its short lived progeny ^{218}Po, ^{214}Pb, ^{214}Bi and ^{214}Po decay within a few hours. Exposures of members of the public to radon and its short lived progeny, as well as to ^{210}Bi, are negligible [291]. The only radionuclides of interest from a public exposure point of view are ^{210}Po and ^{210}Pb. The relatively volatile ^{210}Po escapes from the pellets during sintering and most of it is emitted to the atmosphere, despite intensive scrubbing of the exhaust gases. Although ^{210}Pb is less volatile, at the TIBV plant, the recycling of the ^{210}Pb rich precipitator dust can result in an annual emission of this radionuclide relative to ^{210}Po of up to about 50%, depending on the type of ore used in the process.

ED_005285_00000684-00219

Table 42 shows details for the two year period 1994–1995, when the majority of the ore was obtained from Florida, USA [292, 293], and for the two year period 2002–2003, when the majority of the ore was obtained from Mediterranean and Middle Eastern countries [294, 295]. During the former period, the emission of ^{210}Pb was only 8% of that of ^{210}Po. During the latter period, the total activity input (and hence the emission of ^{210}Po) was significantly lower, but the emission of ^{210}Pb rose to 41% of that of ^{210}Po.

Measurements have shown that the AMADs of the dust particles to which the radionuclides are attached are typically 0.5–1 μm and that the most appropriate lung absorption class is S. The committed effective dose per unit inhaled intake was determined from leaching tests to be 4.3 μSv/Bq for ^{210}Pb and 3.6 μSv/Bq for ^{210}Po [296]. A dose assessment conducted in 1998 showed that the inhalation dose received by a member of the public located in a village 4 km distant was 0.020 mSv/a [289]. Without the recycling of precipitator dust to the sintering plant, it was calculated that this dose would have been 2–5 times lower.

13.4.1.2. Ingestion exposure

Doses received by members of the public living near the TIBV plant were assessed by examining the following exposure pathways [289]:

(a) Ingestion of radioactive fallout from discharges into the atmosphere:
  (i) Soil→crops→humans;
  (ii) Soil→grass→cattle→milk→humans;
  (iii) Soil→grass→cattle→meat→humans;
  (iv) Water→shellfish/crustaceans→humans;
  (v) Water→fish→humans.
(b) Ingestion of radioactivity discharged into the surface water environment:
  (i) Water→shellfish/crustaceans→humans;
  (ii) Water→fish→humans.

TABLE 42. EMISSIONS of ^{210}Pb AND ^{210}Po FROM THE TIBV THERMAL PHOSPHORUS PLANT [292–295]

Period	Ore input (million t)	Proportion of Florida ore (%)	^{210}Po activity (GBq)		^{210}Pb activity (GBq)	
			Input	Emission	Input	Emission
1994–1995	1.186	58	1250.7	1008.9	1250.7	80.1
2002–2003	1.147	0.0	723.5	775.5	723.5	315.0

ED_005285_00000684-00220

TABLE 43. RADIONUCLIDE CONCENTRATION FACTORS USED FOR ASSESSING INGESTION DOSES

Radionuclide	Concentration factor		
	Mussels	Shrimps	Fish
^{210}Po	1000	50 000	2000
^{210}Pb	1000	1000	200

The concentration factors used for determining the activity concentration of radionuclides in marine organisms are given in Table 43. Radionuclide decay and ingrowth were taken into account in the dose assessment. The ingestion dose coefficients for ^{210}Pb and ^{210}Po were 0.69 and 1.2 μSv/Bq, respectively, as specified in the BSS [2]. The results of the assessment showed that the dose arising from ingestion of radionuclides discharged from the TIBV plant was very small — about 0.001 mSv/a.

13.4.2. Use of calcium silicate slag

13.4.2.1. Road construction

The use of calcium silicate slag as a construction material is subject to the requirements for existing exposure situations (see Section 3.1.1 and Ref. [2]). In terms of these requirements, workers are regarded as members of the public for the purposes of radiation protection. The exposure of workers involved in the construction of roads using calcium silicate slag is reported in Ref. [296]. Construction workers are exposed to gamma radiation from the material. The radionuclides ^{214}Pb and ^{214}Bi together contribute 99% of the total gamma dose. The external gamma dose rate 1 m above the mid-point of a layer of phosphorus slag 20 m square and 0.4 m thick was estimated, assuming the ^{238}U and ^{232}Th series radionuclides in the phosphorus slag to be in equilibrium with their respective parents. For ^{238}U series radionuclides, the dose rate was found to be 0.28 μSv/h per unit activity concentration (in becquerels per gram). The corresponding dose rates for ^{232}Th series radionuclides and ^{40}K were 0.43 and 0.03 μSv/h, respectively. These could be taken as maximum values, as increasing the dimensions of the slag layer had no effect on the dose rates. In practice, the average dose rate applicable to road construction workers is significantly lower, for the following reasons:

(a) The shielding effect of machines used in road construction reduces the dose rate to the operator by 50%.

ED_005285_00000684-00221

(b) The width of most roads is less than 20 m.
(c) The worker is not always in the centre of the road bed; the dose rate at the edge is approximately 50% lower.

On the basis of these practical considerations and measurements taken at a road construction site in the Netherlands, and assuming an annual exposure time of 1600 h, the effective dose received in a year by a road construction worker from gamma radiation originating from the slag was estimated to be 0.25 mSv per unit activity concentration of ^{238}U in the slag. The corresponding doses for ^{232}Th and ^{40}K were, respectively, 0.388 and 0.025 mSv per unit activity concentration. Assuming realistic dust levels, sustained for the same annual exposure period of 1600 h, the annual committed effective dose from the inhalation of airborne slag particles was estimated to be 0.03 mSv per unit activity concentration of ^{238}U or ^{232}Th (the same value applied to each radionuclide). The inhalation dose from ^{40}K was negligible. Assuming an ^{238}U activity concentration of 2 Bq/g (which is at the upper end of the normal range in phosphorus slag) and ^{232}Th and ^{40}K activity concentrations each of 0.05 Bq/g, the annual effective dose was thus 0.52 mSv from external gamma exposure and 0.06 mSv from dust inhalation, giving a total annual effective dose of 0.58 mSv.

During road construction, a nearby resident may be exposed to dust, but only for a few hours per day and for a construction period in that person's neighbourhood of a few days to a few weeks in the year of construction. Consequently, comparing the situation with that for a road construction worker, the maximum dose received by a member of the public as a result of the inhalation of phosphorus slag particles during road construction will be no more than a few microsieverts only in that year or those years in which construction work is carried out in that person's neighbourhood.

Once the road is constructed, a member of the public may be exposed to external gamma radiation through the use of that road. Doses received as a result of the incorporation of phosphorus slag from the TIBV plant into roads in the Netherlands have been estimated [296]. It was assumed that the exposure occurs in the middle of the road and that the phosphorus slag layer has a thickness of 0.4 m and a ^{238}U activity concentration of 1.25 Bq/g. The top layer of the road surface, which never contains phosphorus slag, was assumed to have a density of 2350 kg/m^3 and a thickness ranging from 0.06 to 0.19 m, depending on the type of road. The maximum exposure time is limited by the fact that the slag production level of the TIBV plant (600 000 t/a) accounts for less than 4% of the total road bed construction material required in the Netherlands. Therefore, the average exposure time was assumed to be 1.5 h per day. On the basis of these assumptions, the annual dose received by a member of the public was estimated to be about 0.060 mSv for a top layer thickness of 0.06 m, about 0.020 mSv for a

ED_005285_00000684-00222

top layer thickness of 0.13 m, and about 0.001 mSv for a top layer thickness of 0.19 m. These dose estimates are likely to be valid for both private and commercial road users. Commercial road users may spend more time on the road, but such time is usually spent on major highways, which have more than one top layer to obtain the necessary construction strength.

13.4.2.2. Dyke construction

A study commissioned by the Dutch Ministry of the Environment investigated the leaching behaviour of the radionuclides in phosphorus slag with a view to determining the radiological impact of using such material in the construction of dykes [289]. In a hypothetical situation in which all the dykes of the Ijsselmeer (the largest lake in the Netherlands) were assumed to have been constructed using phosphorus slag as a filler material, the maximum annual dose received by a member of the public was calculated to be 0.000 012 mSv; an insignificant level.

13.4.2.3. House construction

In principle, phosphorus slag can be considered for use in house construction and in this regard should be treated no differently from other potential construction materials containing elevated levels of natural radionuclides. However, any such application requires careful assessment on a case-by-case basis. The annual dose received by a house occupant depends on the activity concentration of the material and the nature and extent of its incorporation into the structure of the house. Two contrasting situations are highlighted in Ref. [289]. The use of phosphorus slag in very large quantities could be an unacceptable option because of doses being considerably higher than those associated with normal construction materials. As an extreme example, residing for a year on a surface formed entirely by a thick layer of phosphorus slag is estimated to give rise to an annual dose of 5 mSv. On the other hand, the incorporation of phosphorus slag into concrete used for foundation piles could be an acceptable option.

13.5. REGULATORY CONSIDERATIONS

The radionuclide activity concentrations in the phosphate rock feedstock and the calcium silicate slag may, in some cases, exceed 1 Bq/g by a moderate amount. In facilities that recycle the furnace dust extracted from the precipitator, the activity concentrations of ^{210}Pb and ^{210}Po may increase to several hundred

ED_005285_00000684-00223

becquerels per gram as they progressively accumulate in this dust. Consequently, in terms of the Standards, the production of phosphorus by the thermal process should be considered for regulatory control as a practice. The annual doses received by plant workers are less than 1 mSv, although there is clearly potential for doses several times higher if airborne dust in the furnace area is not adequately controlled. The decay storage of precipitator dust prior to its eventual disposal needs to be carried out under controlled conditions because of the high activity concentrations involved. The annual doses received by members of the public from discharges from the plant have been determined to be far below 1 mSv. The most appropriate regulatory option is likely to be a requirement for authorization, most probably in the form of a registration.

When using the calcium silicate by-product for the construction of structures such as roads and dykes, the doses received annually by construction workers and members of the public are far below 1 mSv and no restrictions on such use would appear to be necessary. The use of the material in the construction of dwellings, while not having been studied specifically, would appear to have the potential for giving rise to doses exceeding 1 mSv because of the likelihood of shorter exposure distances and longer exposure periods. Therefore, a situation specific dose assessment would be needed to determine the need for any restrictions on such use.

Appendix I

URANIUM AND THORIUM DECAY SERIES

The ^{238}U and ^{232}Th series are the main decay series of interest. The ^{235}U decay series is less important for radiation protection purposes, except for the radionuclide ^{227}Ac, which can contribute significantly to inhalation exposure. If necessary, the presence of ^{235}U (and, by implication, its decay progeny) can be taken into account on the basis of the abundances of ^{235}U and ^{238}U in natural uranium (0.711 and 99.284%, respectively) — the corresponding ^{235}U:^{238}U activity ratio is 0.046. Details of the ^{238}U and ^{232}Th decay series, as reported in Ref. [297], are given in Tables 44 and 45, respectively.

PHOSPHATE-CONTAINING PRODUCTS AND THEIR APPLICATIONS

TABLE 49. FOOD AND PHARMACEUTICAL APPLICATIONS

Product and chemical formula	Application
Phosphoric acid	
Orthophosphoric acid, H_3PO_4 in H_2O	Acidulent in cola beverages; sugar refining; acid flavouring agent in jams and jellies; ingredient in bread dough and cake flour; yeast nutrient; cottage cheese production
Ammonium phosphates	
MAP, $NH_4H_2PO_4$	Buffer capacity; nutrient source; brewing
DAP, $(NH_4)_2HPO_4$	Buffer; nutrient source; dough strengthener; firming agent; processing aid; biscuits; brewing; sugar refining; ingredient in dentifrice
Calcium phosphates	
MCP, $Ca(H_2PO_4)_2$ or $Ca(H_2PO_4)_2 \cdot H_2O$	Anhydrous: Bakery applications, including self-raising flour, phosphated flour, self-raising corn meal, consumer prepared mixes and baking powder; calcium supplement in foods Monohydrate: Acidulent for foods and beverages; leavening acid; nutrient; dietary supplement; yeast food dough conditioner
DCP, $CaHPO_4$ or $CaHPO_4 \cdot 2H_2O$	Excipient for tableting; polishing ingredient in dentifrice; mineral, dietary and nutritional supplements Dihydrate: Nutrient; yeast food; leavening agent
Tricalcium phosphate, $Ca_5(OH)PO_4)_3$	Flow promoter for powders; suspension polymerization agent; nutritional mineral supplement; ingredient in dentifrice
Magnesium phosphates	
Magnesium phosphate, $MgHPO_4$, $MgHPO_4 \cdot 3H_2O$	Heat activated leavening agent; ingredient in baked goods including cakes, muffins, biscuits and pancakes
Dimagnesium phosphate, $MgHPO_4 \cdot 3H_2O$	Nutrient source; pH control agent; dietary supplement; flow aid

ED_005285_00000684-00231

TABLE 49. FOOD AND PHARMACEUTICAL APPLICATIONS (cont.)

Product and chemical formula	Application
Sodium phosphates	
Monosodium phosphate, NaH_2PO_4	Buffer and emulsifier in food preparation; acid ingredient in effervescent powders and laxatives; acidifier in non-cola beverages; buffers the pH of cheese and interacts with milk proteins to promote emulsification; gelling aid in desserts; prevents discoloration of mixtures of egg whites and yolks
Disodium phosphate, Na_2HPO_4 or $Na_2HPO_4 \cdot 2H_2O$	Anhydrous: Buffer; emulsifier or texturizer for instant puddings, evaporated milk, processed cheese, cereals, pre-cooked meats and pasta products; pharmaceuticals; water treatment in food processing Dihydrate: Emulsifier, especially for processed cheese; texturizer; buffer; nutritional mineral supplement
Trisodium phosphate, Na_3PO_4 or $4(Na_3PO_4 \cdot 12H_2O) \cdot NaOH$	Processed cheese and cheese products; quick cooking cereals; meat, poultry and cheese processing; post-chill antimicrobial treatment for raw poultry; clarifier in sugar mills
Sodium acid pyrophosphate, $Na_2H_2P_2O_7$	Leavening acid for baking powder; cake mixes; refrigerated or frozen dough and cake doughnuts; additive to non-dairy creamers; protects processed potatoes from iron induced darkening; decreases or prevents the formation of struvite crystals in albacore tuna; accelerates the development of a red colour in emulsion type meat products; emulsifying agent in cheese processing
Tetrasodium pyrophosphate, $Na_4P_2O_7$	Production of metal pyrophosphates; dispersant in malted milk powders; coagulant in instant puddings; colour and moisture retention in processed meats; prevents the formation of struvite crystals in canned seafoods and ice crystals in ice cream
Glassy sodium polyphosphates, sodium hexametaphosphates, $Na_{(n+2)}P_nO_{(3n+1)}$	Sequestration of multivalent ions to inhibit oxidative rancidity in food; water binding in cured meats and reduction of moisture loss during thawing and cooking of poultry and pork; emulsifies fat and protein; water treatment agent to prevent staining of the exterior of canned meat and poultry; scalding agent for meat and poultry; suspension agent in food
Sodium trimetaphosphate, $(NaPO_3)_3$	Food processing; starch modification; esterification of food starch; pharmaceuticals
Sodium aluminium phosphate, $Na_2Al_2H_{15}(PO_4)_8$	Heat triggered leavening acid used in bakery products such as refrigerated and frozen products; commercial baking powders and prepared mixes

ED_005285_00000684-00232

TABLE 49. FOOD AND PHARMACEUTICAL APPLICATIONS (cont.)

Product and chemical formula	Application
Potassium phosphates	
Dipotassium phosphate, K_2HPO_4	Nutrient for antibiotic production; pharmaceutical aid (buffering agent); emulsifier in non-dairy coffee creamers; cheese processing
Tripotassium phosphate, K_3PO_4	Emulsifier; alkaline buffer; pharmaceuticals
Potassium tripolyphosphate, $K_5P_3O_{10}$	Meat treatment for moisture binding; emulsifier and suspension agent in food
Phosphate blends	
Sodium acid pyrophosphate + calcium chloride, $Na_2H_2P_2O_7$, $CaCl_2$; l-ascorbic acid, $C_5H_8P_2O_7$; Citric acid, $C_3H_4(OH)(COOH)_3 \cdot H_2O$	Maintains the colour, texture and quality of fresh fruit and vegetables; increases the useful shelf life of most treated foods; delays the onset of oxidative and enzymatic browning
Disodium or trisodium phosphate + sodium metaphosphate, Na_2HPO_4 or Na_3PO_4, $(NaPO_3)_n$, n = 1000–5000	Emulsifying agent in pasteurized processed cheese; protein modifier; improves viscosity, melt spread, body and hardness
Sodium aluminium phosphate + MCP, $Na_3Al_2H_{15}(PO_4)_8$, $Ca(H_2PO_4)_2$ or $Ca(H_2PO_4)_2 \cdot H_2O$, $CaCO_3$, SiO_2	Anhydrous: Double acting leavening agent in self-raising flour, self-raising corn meal and biscuit mixes for a full volumed, light product Monohydrate: Acidulent and leavening agent in bakery applications such as pancakes, waffles, cakes and other prepared mixes; adding to the structure resiliency, crumb whiteness and baking tolerance of white cake mixes
Polyphosphate blends, $Na_5P_3O_{10}$ $Na_{(n+2)}P_nO_{(3n+1)}$, n = 10–16	Sequestration of multivalent metal ions to inhibit oxidative rancidity; reduces moisture loss during thawing and cooking; emulsifies fat and protein; improves solubility; improves gelation properties in surimi; gives a neutral pH and improves emulsion stability
Phosphorus chlorides and oxides	
Phosphorus trichloride, PCl_3	Intermediate in the manufacture of phosphate esters used in the production of several pharmaceuticals
Phosphorus pentachloride, PCl_5 and phosphorus oxychloride, $POCl_3$	Chlorinating agent used in the production of antibiotics
Phosphorus pentoxide, P_2O_5	Used in various organic synthesis reactions to produce intermediates for pharmaceuticals

ED_005285_00000684-00233

TABLE 50. INDUSTRIAL, AGRICULTURAL AND DOMESTIC APPLICATIONS

Product and chemical formula	Application
Phosphoric acid	
Orthophosphoric acid, H_3PO_4 in H_2O	Commercial grade: Manufacture of phosphates and fertilizers; acid cleaners; aluminium brighteners; metal phosphatizing; cement processing; leather tanning; fire bricks, silica bricks, crucibles and moulds; dental cements; opal glass and special glasses, such as that for sodium lamps; toilet preparations; varnish; synthetic rubber; boiler water treatment; potable water treatment Furnace grade: Semiconductor etchant; printed circuit board cleaner; reagent for analytical chemistry
Polyphosphoric acid, $H_{n+2}P_nO_{3n+1}$ Superphosphoric acid (mixture of ortho- and polyphosphoric acids)	Production of phosphates, phosphate esters; phosphorylation of polyols; metal cleaning and phosphatizing; aluminium brightening; electrolyte for fuel cells; refractory bonding; catalyst in organic reactions such as rearrangements, polymerization, dehydration, hydrolysis, nitration, bromination and cyclization
Ammonium phosphates	
MAP, $NH_4H_2PO_4$	Liquid and dry speciality fertilizer; fire and afterglow retardant; bonding agent in ceramics; corrosion inhibitors
DAP, $(NH_4)_2HPO_4$	Liquid and dry speciality fertilizer; fire and afterglow retardant; bonding agent in ceramics; corrosion inhibitors; welding of tin, copper, brass and zinc
Calcium phosphates	
MCP, $Ca(H_2PO_4)_2$ or $Ca(H_2PO_4)_2 \cdot H_2O$	Feed; fertilizer; opaque glass manufacture; paint preparations for steel enamels
DCP, $CaHPO_4$ or $CaHPO_4 \cdot 2H_2O$	Feed; mineral supplement; inner coating of fluorescent lamps; glass manufacture
Tricalcium phosphate, $Ca_5(PO_4)_3$	Feed; flow conditioning and anticaking agent; flow agent in dry powder fire extinguishers; additive to glues and resins in manufacture of plywood and granulated fertilizers; expandable polystyrene manufacture; fluorescent lamps; whitening of porcelain; enamels; glass manufacture

ED_005285_00000684-00234

TABLE 50. INDUSTRIAL, AGRICULTURAL AND DOMESTIC APPLICATIONS (cont.)

Product and chemical formula	Application
Sodium phosphates	
Monosodium phosphate, NaH_2PO_4	Metal cleaning and phosphatizing compounds; boiler water conditioning; dyeing of cotton; mineral supplement; buffer in electroplating; dairy cleaner to remove milkstones; feed supplement; shampoos
Disodium phosphate, Na_2HPO_4 or $Na_2HPO_4 \cdot 2H_2O$	Pigments; enamels; ceramics; detergents; welding Anhydrous: Boiler water conditioning; potable water treatment; phosphatizing metal cleaner; buffering agent in textile dye baths
Trisodium phosphate, Na_3PO_4 or $4(Na_3PO_4 \cdot 12H_2O) \cdot NaOH$	Anhydrous: Industrial and household cleaners; potable water treatment; bottle washing; textile washing; dyeing and bleaching; photographic film developer bath ingredient; builder and filler for soaps; paint remover; metal degreasing Dodecahydrate: Ingredient in alkaline cleaners to emulsify fats, greases and oils; buffering at high pH
Sodium acid pyrophosphate, $Na_2H_2P_2O_7$	Acid cleaners; metal polishes; oil well drilling muds; buffer; detergents; iron phosphatizing; dairy cleaner to remove milkstones; pigment dispersant in water based paints
Tetrasodium pyrophosphate, $Na_4P_2O_7$	Detergents and soaps; dispersant in clay processing; oil well drilling mud conditioner; water conditioning and textile processing; pitch control in paper mills; bleach bath stabilizer; alkaline metal cleaners; paper coating and filling; soil stabilization; manufacture of plastic granules for injection moulding
Glassy sodium polyphosphates, sodium hexametaphosphates, $Na_{(n+2)}P_nO_{(3n+1)}$	Industrial water treatment; potable water treatment; dispersion of pigmenting and dyeing operations in the textile industry; film development; oil well drilling mud deflocculant; sequestrant and suspension agent in clay processing; detergents; refractory binding
Sodium tripolyphosphate, $Na_5P_3O_{10}$ or $Na_5P_3O_{10} \cdot 6H_2O$	Anhydrous: Consumer and industrial cleaning products; detergents, such as for dishwashers, laundry and vehicle washing; potable water treatment; personal care products such as bath beads; clay slurry deflocculation; soil stabilization; cement manufacture; flotation reagent in mining; pitch control in wood pulping; textile operations Hexahydrate: Ingredient in compounds where rapid solubility or freedom from caking is essential; bath water conditioners
Sodium trimetaphosphate, $(NaPO_3)_3$	Consumer and industrial detergents and cleaning products; control of product density; dry bleach bases; phosphate detergent intermediate; potable water treatment

ED_005285_00000684-00235

TABLE 50. INDUSTRIAL, AGRICULTURAL AND DOMESTIC APPLICATIONS (cont.)

Product and chemical formula	Application
Potassium phosphates	
Monopotassium phosphate, KH_2PO_4	Seedbed fertilizer supplements; speciality and household fertilizers; nutrient for bacteria in biological waste treatment; potable water treatment; buffer capacity
Dipotassium phosphate, K_2HPO_4	Corrosion inhibitor in antifreeze; enamel production and paper processing; liquid fertilizers; potable water treatment; dispersion medium in liquid detergents
Tripotassium phosphate, K_3PO_4	Rubber processing; industrial and household cleaners; water conditioning; bottle washing; textile washing; dyeing and bleaching; photographic film developer bath ingredient; builder and filler for soaps; paint remover; metal degreasing
Potassium tripolyphosphate, $K_5P_3O_{10}$	Pigment dispersion in latex emulsion paints; sequestrant in liquid detergents; suspension agent; speciality boiler water compounds
Tetrapotassium pyrophosphate, $K_4P_2O_7$	Builder for liquid detergents and liquid potash soaps; synthetic rubber; buffer and sequestrant in electroplating baths; speciality boiler compounds; dispersant in water based paints; emulsifier of oils and greases; deflocculant in oil well drilling muds
Phosphate blends	
Sodium potassium polyphosphates	Builder for liquid consumer and industrial cleaning products
Phosphorus sulphides	
Phosphorus sesquisulphide, P_4S_3	Safety matches
Phosphorus pentasulphide, P_4S_{10}	Petroleum and lubricant additive intermediate; insecticide intermediate; ore flotation reagent; reaction with alcohols, mercaptans, amines and organic acids to produce thiophosphorus derivatives

ED_005285_00000684-00236

TABLE 50. INDUSTRIAL, AGRICULTURAL AND DOMESTIC APPLICATIONS (cont.)

Product and chemical formula	Application
Phosphorus chlorides and oxides	
Phosphorus trichloride, PCl_3	Intermediate in the manufacture of phosphate esters (used in plasticizers, hydraulic fluids, flame retardants and as a cryoscopy solvent), organophosphorus pesticides, organophosphines, phosphorus oxychloride, surfactants, stabilizers, defoamers and paper products; chlorinating agent; production of special metallic deposits
Phosphorus pentachloride, PCl_5	Chlorinating agent in the manufacture of dyes; catalyst for the condensation and cyclization reaction and to improve the grain structure of light-metal castings; production of materials by the agricultural industry; key ingredient in specialized fire retardants
Phosphorus oxychloride, $POCl_3$	Production of cosmetics and flame retardants
Phosphorus pentoxide, P_2O_5	Use in various organic synthesis reactions to produce intermediates for speciality chemicals; production of phosphate esters; drying agent (making use of its hygroscopic properties)

Appendix IV

COMPOSITION OF PHOSPHATE ROCK

Data on the composition of phosphate rock are given in Table 51 for the main chemical constituents, Table 52 for heavy metals and Table 53 for radionuclides. Some values have been rounded. The values reported are not necessarily representative of current production. The phosphate rock is derived from ore of sedimentary origin except where stated otherwise.

Appendix V

METHODS OF PHOSPHORIC ACID PRODUCTION USING SULPHURIC ACID DIGESTION

V.1. THE DIHYDRATE (DH) METHOD

The DH method is the most widely used of three so-called 'weak acid' methods. The acid digestion is carried out at a temperature of 70–85°C to yield phosphoric acid with a relatively low P_2O_5 content of 24–32% and dihydrate phosphogypsum crystals. A simplified schematic representation of the DH method is shown in Fig. 72.

In order to minimize the amount of unreacted rock remaining within the phosphogypsum, the particle sizes of the feedstock must lie within certain bounds. Some grades of commercial rock already meet this requirement, but most feedstocks require particle size reduction, usually using a ball mill or rod mill. In general, the degree of agitation and the amount of free sulphate in the attack tank determine the amount of milling required — a low free sulphate content and good agitation allows the use of coarser rock particles. Typically, the dihydrate process requires a feedstock particle size distribution in which 60–70% of the particles are less than about 100 μm. Traditional dry milling methods first require the moisture content of the rock to be reduced from 10–15% to, typically, 2%. The energy costs associated with this drying step have encouraged the industry to convert to wet milling, initially using fresh water but more recently making

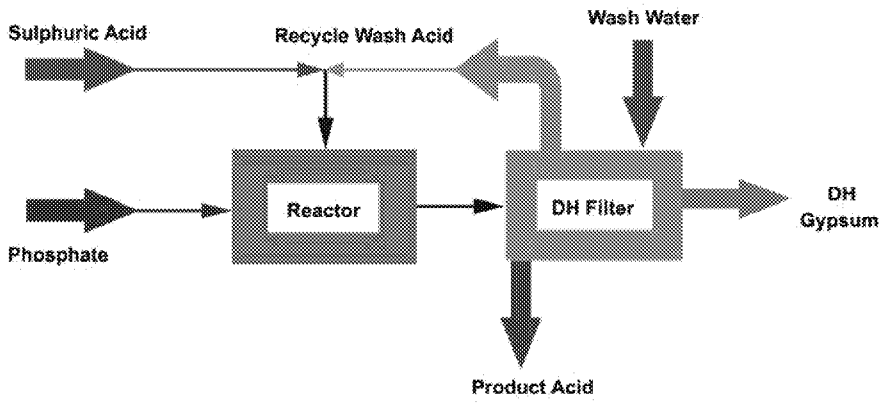

FIG. 72. The DH method [65].

ED_005285_00000684-00245

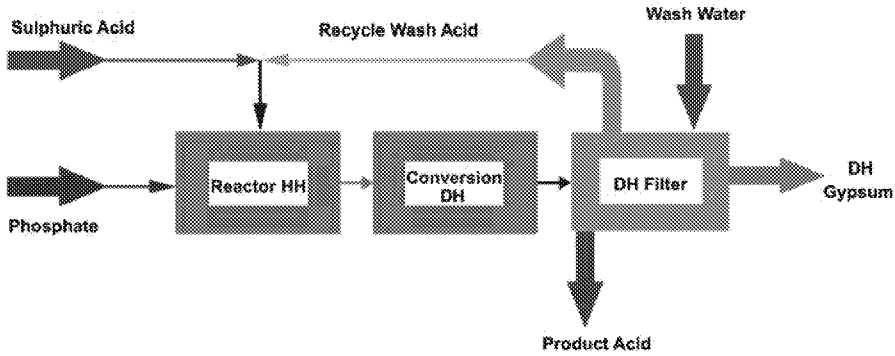

FIG. 73. The HRC method [65].

increased use of the partially neutralized acidic process water ('pond water') recycled from the phosphoric acid production process. In some facilities, the mill liners are manufactured from high alloy materials, allowing the use of 100% pond water without encountering corrosion problems. The use of pond water in this manner reduces the consumption of water and allows the recovery of P_2O_5.

Although a single attack tank is sometimes used, the reaction system more commonly comprises a series of separate tanks or tank compartments. The phosphogypsum crystals produced from the acid digestion process are separated from the phosphoric acid by vacuum filtration followed by up to four stages of countercurrent washing.

V.2. THE HEMIHYDRATE RECRYSTALLIZATION (HRC) METHOD

The HRC method, the second of the three weak acid methods, resembles that of the multiple reactor dihydrate process, except that the initial attack tank operates under hemihydrate conditions (for instance, at a temperature of 90–110°C). Subsequent attack tanks operate under conditions favouring the rehydration of the hemihydrate phosphogypsum to dihydrate phosphogypsum. The hemihydrate phosphogypsum is recrystallized to the dihydrate form without intermediate hemihydrate separation. The dihydrate crystals are then separated from the phosphoric acid by filtration, as described in Section 5.1.1.1. The method yields phosphoric acid with a P_2O_5 content of 30–32%, no better than that obtainable from the DH method (prior to concentration by evaporation), but the phosphogypsum has a higher level of purity. A simplified schematic representation of the method is shown in Fig. 73.

ED_005285_00000684-00246

In a variation of the HRC method, known as the 'repulping process', the phosphogypsum is converted back into a slurry and pumped to a second filtration step. The wash water from this second filtration step is returned to the first filtration where it is reused as the wash water for that step. Most of the free acid which is not removed in the first filtration step is removed in the second filtration step. Depending on the amount of free acid, the repulping process can improve the process efficiency by up to 2%. The residual P_2O_5 content of the phosphogypsum is reduced to only 2.5% [85].

V.3. THE DIHYDRATE–HEMIHYDRATE (DH/HH) METHOD

The DH/HH method is the third of the three weak acid methods. The phosphate rock feedstock is digested under dihydrate conditions and the phosphoric acid and dihydrate phosphogypsum are separated by filtration. However, the phosphogypsum crystals, rather than simply being washed at that stage, are instead converted to the hemihydrate form by heating with steam and additional sulphuric acid. The resulting hemihydrate phosphogypsum slurry is filtered and the liquor, containing residual P_2O_5, is returned to the initial dihydrate process step, thus avoiding the need for achieving a high degree of P_2O_5 recovery during the separation of the acid from the dihydrate phosphogypsum. The hemihydrate recrystallization stage operates at a P_2O_5 concentration of about 20–30% and a sulphuric acid concentration of 10–20%. The phosphoric acid product contains 32–36% P_2O_5. The P_2O_5 content of the phosphogypsum is only 1% [85]. A simplified schematic representation of the method is shown in Fig. 74.

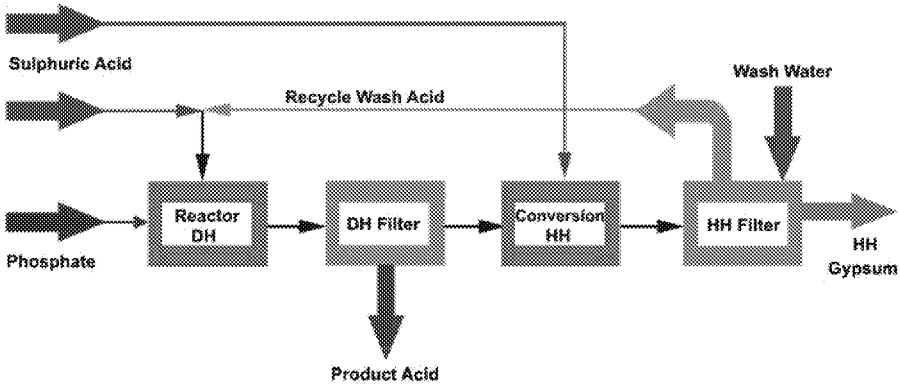

FIG. 74. The DH/HH method [65].

ED_005285_00000684-00247

V.4. THE HEMIHYDRATE (HH) PROCESS

The HH process is the first of two so-called 'strong acid' methods. The acid digestion conditions are controlled such that the phosphogypsum is precipitated in the hemihydrate form. The reaction temperature, for instance, is 90–110°C, higher than that used for dihydrate phosphogypsum production. Phosphoric acid with a P_2O_5 content of 36–52% is produced directly, resulting in significant energy and cost savings, in that the reaction vessels are similar to those used in the dihydrate method, but the need for prior particle size reduction is minimized or avoided. The P_2O_5 content of the phosphogypsum is relatively high (up to 8% [85]). A simplified schematic representation of the method is shown in Fig. 75.

V.5. THE HEMIDIHYDRATE (HDH) METHOD

The HDH method is the second of the two 'strong acid' methods. As with the HH method, the acid digestion conditions are such that the phosphogypsum is precipitated in the hemihydrate form. The hemihydrate crystals are then recrystallized to the dihydrate form and separated by filtration. The filtrate is returned to the process. The phosphoric acid product is removed by filtration at a strength of 42–45%, that is, similar to the values achievable with the HH method but in a narrower range. A simplified schematic representation of the method is shown in Fig. 76.

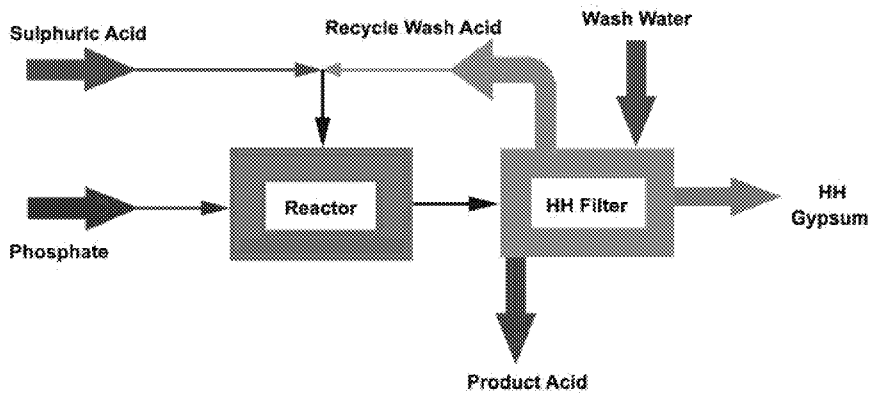

FIG. 75. The HH method [65].

Appendix VI

COMPOSITION OF PHOSPHOGYPSUM

Data on the compostion of phosphogypsum are given in Table 54 for the main chemical constituents, Table 55 for heavy metals and Table 56 for radionuclides. Some values have been rounded.

TABLE 54. MAIN CHEMICAL CONSTITUENTS OF PHOSPHOGYPSUM [48, 85, 133, 205, 209, 217, 325–330]

	Concentration (%)	
	Minimum	Maximum
CaO	24	34
SO_4	48	58
SiO_2	0.5	18
Na_2O	0.12	10
C (organic)	0.1	2.5
F	0.1	1.8
P_2O_5	0.05	8
Al_2O_3	0.05	0.6
Cl	0.035	0.045
MgO	0.01	0.54
Fe_2O_3	0.01	0.25

ED_005285_00000684-00250

TABLE 55. HEAVY METALS AND RARE EARTH ELEMENTS IN PHOSPHOGYPSUM [48, 74, 75, 77, 80, 137–139, 208, 219, 316, 325–327, 331, 332]

Element	Concentration (ppm)		
	Minimum	Maximum[a]	
Ti	26	470	
V	2	40	(190)
Cr	1.6	75	(594)
Mn	3.5	20	
Co	0.05	2.3	
Ni	1.7	250	
Cu	2	195	(508)
Zn	4	315	(351)
As	1.0	42	
Se	0.5	75	(249)
Sr	10	1118	(1606)
Y	2	156	
Zr	10	110[b]	(398)
Mo	1	16	
Ag	0.4	5	(73)
Cd	0.8[c]	40	
Ba	20	236	(810)
Hg	0.005	10	
Pb	0.5	16	(73)
Th	0.4	4	(75)
U	0.5	13.8	(19)
La	42	90	(419)
Ce	21	143	(425)
Nd	30	67	(352)
Sm	5	13	(60)
Eu	1.1	3	(15)
Yb	2.1	3.2	(21)
Lu	0.3	0.4	(2)

[a] Values in parentheses are maximum values reported for the fine fraction (<20 μm) [138, 139].
[b] A value of 700 ppm was reported for phosphogypsum of igneous origin [48].
[c] It is reported that, by adapting the parameters of the sulphuric acid digestion process, the cadmium concentration in the phosphogypsum can be reduced to less than 0.5 ppm, although this is offset by a higher cadmium concentration in the phosphoric acid [85].

Annex I

ASSESSMENT OF THE SOLUBILITY OF AIRBORNE DUST PARTICLES

I–1. INTRODUCTION

Radioactive particles deposited in the respiratory tract are removed by three main routes:

(i) Absorption into the blood;
(ii) Transport to the gastrointestinal tract;
(iii) Transport to regional lymph nodes.

Absorption into the blood involves the dissociation of particles and the uptake into blood of soluble substances and material dissociated from particles. The rate of particle dissolution in lung fluids is a crucial factor in determining the absorption rate. In the absence of specific data on absorption rates, default values are specified by the International Commission on Radiological Protection (ICRP) for the three general lung solubility classes of fast (F), medium (M) and slow (S) [I–1].

When conducting a dose assessment, the assignment of an appropriate solubility class tends to be based on conservative assumptions, leading to the likelihood of the dose being overestimated. This problem can be avoided by directly measuring the solubility of inhaled radioactive particles. In vivo measurements in humans are the most reliable source of data, but such data may be unavailable or insufficient, especially for the inhalation of airborne dust particles containing radionuclides of natural origin. As an alternative method, in vitro dissolution tests have been developed and used as research tools to estimate the solubility of particles. In the study reported in Ref. [I–2], and summarized in this annex, dissolution fractions and dissolution rates were determined for several key radionuclides of the ^{238}U decay series contained within airborne dust particles generated in phosphate fertilizer production plants. Measurements were made using a simulated lung fluid in an in vitro dissolution system.

I–2. ASSESSMENT METHOD

Samples of settled dust, aerosol particles and bulk products originating from the phosphate industry in central Florida, USA, were employed for solubility testing. Bulk products are produced via a dry granulation process using

ED_005285_00000684-00277

phosphoric acid as the feedstock. Dust originates from ungranulated products or small fragments of bulk products, which can be easily suspended as aerosols and subsequently settled. Since the granulator area is located inside a building, there is little possibility of airborne contaminants other than phosphate products. Therefore, the main components of the three types of dissolution test sample are likely to be similar. The sample materials comprised monoammonium phosphate (MAP) and diammonium phosphate (DAP).

The sizes of settled dust samples were found to be widely distributed, ranging from less than 1 μm to greater than 100 μm. The particle inhalability generally decreases with increasing particle size [I–1]. A typical upper size limit for suspended particles is 100 μm [I–3]. Large particles are seldom inhaled and, thus, contribute little to the committed effective dose. Therefore, the large particles were removed from settled dust with a 76 μm sieve prior to conducting the dissolution tests.

The particle size would be expected to influence the dissolution rate because of its relationship to the particle surface area — smaller particles would dissolve more rapidly than larger particles because a larger proportion of the particle mass is available for reaction by being close to the surface [I–4, I–5]. Samples of airborne particles smaller than 10 μm and samples of bulk products (MAP and DAP, with granule diameters of approximately 3 mm) were additionally tested for any potential size effect on particle solubility in the lung. The airborne dust samples were collected at the granulator area at two phosphate processing plants, using a PM_{10} high volume sampler (Sierra-Andersen, Model 1200) at a flow rate of 1130 L/min for 3 d. Particles collected on quartz fibre filters were mechanically detached for dissolution testing.

Various types of in vitro dissolution technique have been used in previous studies [I–4], including:

(i) Flow systems;
(ii) Static systems;
(iii) Batch methods.

The radionuclide mass concentration in phosphate particles is rather low. For example, the mass fraction of uranium in MAP and DAP ranges from 0.014 to 0.025% [I–6]. For dissolution techniques (i) and (ii), there is a lower limit on the applicable mass of target material. Therefore, dissolution technique (iii) — the batch method — was selected in order to increase the quantity of particles and, thus, increase the radionuclide concentrations in solution for analysis.

In previous studies [I–7, I–8], serum ultrafiltrate (SUF) had proved successful as a simulated lung fluid and was, therefore, chosen for this investigation. The SUF was prepared according to the procedures reported in those earlier studies and was

ED_005285_00000684-00278

used in conjunction with the batch method. Samples of material weighing 5 g were suspended in 200 mL of SUF in a flask, which was immersed in a water bath at a controlled temperature of 37°C. For the DAP samples, the pH of the stirred suspension was maintained within the range 7.3–7.4. For the MAP samples, the high fractional dissolution of the material caused the pH to decrease to 5.6–5.8 during the first day. After extracting the solution following that first day, the pH could subsequently be controlled within the range 7.3–7.4 by passing a mixture of 5% CO_2 and 95% air through the solution at a flow rate of 200–1000 mL/min. Leachate samples were collected initially after one day and periodically thereafter for a maximum of 50–85 d. To collect the leachate sample, the entire suspension was first passed through a 0.5 μm filter membrane. After separation of the dissolved fraction, the remaining undissolved particles were washed with 20 mL of SUF and the mixture passed through the same membrane. The filtrate was then passed through a 0.1 μm filter membrane. This double filtration method significantly reduced the possibility of leachate contamination by undissolved particles, which would have resulted in an overestimation of the dissolution rate. The double filtered leachate samples were reserved for subsequent analysis. The undissolved particles were resuspended in 200 mL of fresh SUF for the next leaching and filtration step.

The sample residues obtained from the dissolution tests were dissolved using a mixture of HF and HNO_3 [I–9]. Approximately 40 mg of residues were placed into Savillex screw-top Teflon vials and 0.5 mL of optima grade concentrated HF and 2.5 mL of optima grade concentrated HNO_3 were added. After placing the vials in an oven at 100°C for 24 h, the samples were evaporated to dryness on a hotplate. Then, 3 mL of optima grade concentrated HNO_3 doped with HCl were added to the samples, the vials heated on the hotplate for 24 h and then evaporated once again. The final residues were redissolved in 4 mL of 5% HNO_3 and diluted (about 2000 times) in preparation for analysis.

The solubilities of uranium, thorium and lead in the particles were characterized by measuring their isotope concentrations in the leachates and residues. The measurements were performed by high resolution inductively coupled plasma mass spectrometry (Thermo Electron Corp., Finnigan Element 2). The use of inductively coupled plasma mass spectrometry for health physics studies has increased in recent years owing to its high sensitivity and rapid procedure [I–10] to [I–13]. The intensities of the isotopes were measured at medium resolution. The measuring equipment was calibrated using gravimetrically prepared uranium, thorium and lead calibration standards. The greatest contributor to worker inhalation dose in the Florida phosphate industry is ^{230}Th, followed by ^{234}U and ^{238}U, respectively. Other radionuclides in the ^{238}U series make trivial contributions to worker doses owing to either their relatively low inhalation dose coefficients (^{234}Th and ^{210}Bi) or their low activity concentrations in MAP and DAP aerosol particles (^{226}Ra and ^{210}Po). Although the activity concentrations of ^{234}U,

ED_005285_00000684-00279

^{230}Th and ^{210}Pb in the SUF were comparable to that of ^{238}U, their mass concentrations were too low to measure by mass spectroscopy as their half-lives are short in comparison to that of ^{238}U. The mass concentrations in the SUF were highest for ^{238}U among the uranium isotopes, for ^{232}Th among the thorium isotopes, and for ^{208}Pb among the lead isotopes. Consequently, the solubilities of uranium, thorium and lead were determined from direct measurement of ^{238}U, ^{232}Th and ^{208}Pb.

Since SUF contains background levels of ^{232}Th, the concentrations of ^{232}Th in most leachate samples were below the detection limit — the mean, median, and maximum values of the detection limit were 0.89 ± 0.36, 1.03 and 1.15 mg/L, respectively. In such situations, the concentration of ^{232}Th was taken to be the maximum value of the detection limit. This conservative approach was taken in the light of the fact that an increased blood absorption of ^{230}Th will result in a corresponding increase in the worker effective dose.

The remaining mass fraction at each extraction time step was calculated using the following expression:

$$\text{Remaining fraction} = \frac{M_T - \sum_i M_i}{M_T} \qquad \text{(I–1)}$$

where M_T is the original mass of phosphate ions, ^{238}U, ^{232}Th or ^{208}Pb in the particle sample, and M_i is dissolved mass at each extraction. M_T was estimated as the sum of the cumulative masses measured in the leachate for all extraction steps and the final residual mass at the end of the dissolution test. Dissolution kinetics were expressed as the sum of two exponential functions as given in the lung clearance model described in Ref. [I–1]:

$$\text{Remaining fraction} = f_r e^{-s_r t} + f_s e^{-s_s t} \qquad \text{(I–2)}$$

where f_r and s_r are the dissolution fraction and rate constant for the rapid dissolution component, respectively, f_s and s_s are the corresponding values for the slow dissolution component, and t is the elapsed time [I–4]. Values of f_r, f_s and s_s were determined by means of a least squares analysis using SigmaPlot version 8.0 (SPSS, Inc.) [I–7]. Since the first leachate samples were collected only after one day, the solubility after shorter time periods (for instance, 10 min) was not directly measurable. The ICRP default value of 100 d^{-1} [I–1] was, thus, assigned as the rapid dissolution rate, s_r. A similar approach was adopted in Ref. [I–7].

It was postulated that the lung solubilities of radionuclides contained in the airborne particles of phosphate product are governed mainly by their chemical forms in the particles. The measurements showed that there was no statistically

ED_005285_00000684-00280

significant correlation between the dissolution rate and the product type or particle size. Since the majority of the surrounding phosphate matrix in the particle dissolved very rapidly, particle size did not appear to influence the solubility to any great extent.

I–3. RESULTS

The results of the investigation are shown in Fig. I–1. While the majority of the phosphate (the main component of the inhaled particle) dissolved rapidly in the simulated lung fluid, the dissolution of uranium, thorium and lead was generally less rapid. Between 3 and 14% of the ^{238}U in the particles dissolved rapidly in the simulated lung fluid, while the remaining fraction dissolved with a half-time of 91–315 d. The dissolution kinetics for ^{238}U were noted to be close to, but slightly slower than, those of materials in lung solubility class M in the lung clearance model described in Ref. [I–1]. For ^{232}Th, less than 1.4% of the radioactivity dissolved rapidly in the simulated lung fluid, with the remaining fraction dissolving with a half-time of more than 866 d. Solubility data for ^{208}Pb displayed a wide sample-to-sample variation. Between 3 and 41% of the ^{208}Pb dissolved rapidly, while the remainder dissolved more slowly with a half-time of 38–866 d. It was concluded that, for the purposes of radiation protection of workers in Florida phosphate processing plants, the data supported the selection of lung solubility class M for uranium and lead and class S for thorium.

Annex II

REMEDIATION OF COASTAL AND MARINE PHOSPHATE RESIDUE DEPOSITS: THE TAPARURA PROJECT AT SFAX, TUNISIA

II–1. TUNISIAN PHOSPHATE DEPOSITS

Tunisia's phosphate deposits are found in the north-east of the country, as well as further south. Of these, the most significant are located in the Gafsa basin in the south-central region. In 2010, the Compagnie des Phosphates de Gafsa produced 7.6 million t of phosphate rock from seven open-pit mines and one underground mine, making Tunisia the world's fifth largest producer. Phosphate rock and phosphate products (phosphoric acid, triple superphosphate (TSP), diammonium phosphate (DAP) and dicalcium phosphate (DCP)) together comprise Tunisia's primary export and are sold to 50 countries in five continents.

II–2. MINING AND PRODUCTION

Compagnie des Phosphates de Gafsa supplies approximately 80% of its phosphate rock production to the Groupe Chimique Tunisien, which operates several phosphoric acid plants. The remaining 20% of its production is exported through the port of Sfax. Groupe Chimique Tunisien has the capacity to produce more than 700 000 t/a of phosphoric acid, 1 million t/a of TSP, 600 000 t/a of DAP, 300 000 t/a of nitrogen-phosphate-potash and 100 000 t/a of monoammonium phosphate (MAP).

Groupe Chimique Tunisien owns four industrial production centres located in Sfax and M'dhilla (for TSP), Gabès (for phosphoric acid, DAP and DCP) and Skhira (for phosphoric acid). Approximately 800 000 t of TSP is produced annually at the Sfax and M'dhilla sites.

II–3. PHOSPHATE INDUSTRY ACTIVITIES AT THE CITY OF SFAX

The city of Sfax is located on the Gulf of Gabès, 270 km southeast of Tunis, and has a population of 340 000 (2005). It is the capital of the Sfax Governorate and is a leading centre of industry and commerce. Sfax is the largest port in Tunisia, handling the export of both phosphate rock and phosphate products.

ED_005285_00000684-00284

Rock for export is transported by rail to the docks from the Metlaoui and Jebel M'dhilla mining areas.

The Sfax plant, which commenced production in 1952, was the first phosphate rock processing facility in Tunisia. It was also the birthplace of the multi-tank processing technology known as SIAPE, named after the company Société Industrielle d'Acide Phosphorique et d'Engrais that first developed it. SIAPE is now part of Groupe Chimique Tunisien. This method was designed to handle low grade phosphate ores. It was implemented at the phosphoric acid and TSP plants in Gabes, M'dhilla and Skhira.

The Sfax harbour facility was the location of an industrial area which included a phosphate plant that commenced operation in 1964. Phosphogypsum and other residues were discharged directly on to the beaches and into shallow offshore areas (the latter being, in effect, a 'dilute and disperse' management option), resulting in the accumulation of a large, square phosphogypsum stack close to the harbour and town (see Figs II–1 and II–2). As the stack increased in size, protective sea walls were constructed to confine the material and prevent erosion. The phosphogypsum residue contained low levels of metals, such as cadmium, arsenic and nickel, as well as radionuclides of the uranium decay series and, to a lesser extent, the thorium decay series. The average ^{238}U and ^{226}Ra concentrations in the Sfax phosphogypsum residues are at the lower end of the ranges reported worldwide. The ^{226}Ra activity concentration is approximately 0.4 Bq/g. The beaches were closed and swimming was forbidden in 1978 owing to the pollution arising from the phosphogypsum stack. The plant itself was closed in 1991. The stack, which covered an area of approximately 50 ha and reached a height of up to 8 m above sea level, was surrounded by a crusty layer of phosphogypsum ('plaque') with an area of 90 ha and a depth of up to 3 m.

Public exposure from operating phosphoric acid and fertilizer plants can occur through the inhalation of radon gas released from phosphogypsum stacks and through the migration of radionuclides into groundwater and surface water bodies, including the sea. Previous studies [II–1, II–2] have shown that the discharge of phosphogypsum into surface water bodies can result in significantly elevated levels of radionuclides, such as ^{210}Po in water, sediments and biota. Exposures are estimated to be in the range 2–10 μSv/a [II–3], with maximum values of up to 150 μSv/a [II–4]. The highest values occur where there are discharges to marine water and freshwater, resulting in the contamination of fish and shellfish used as local foodstuffs.

ED_005285_00000684-00285

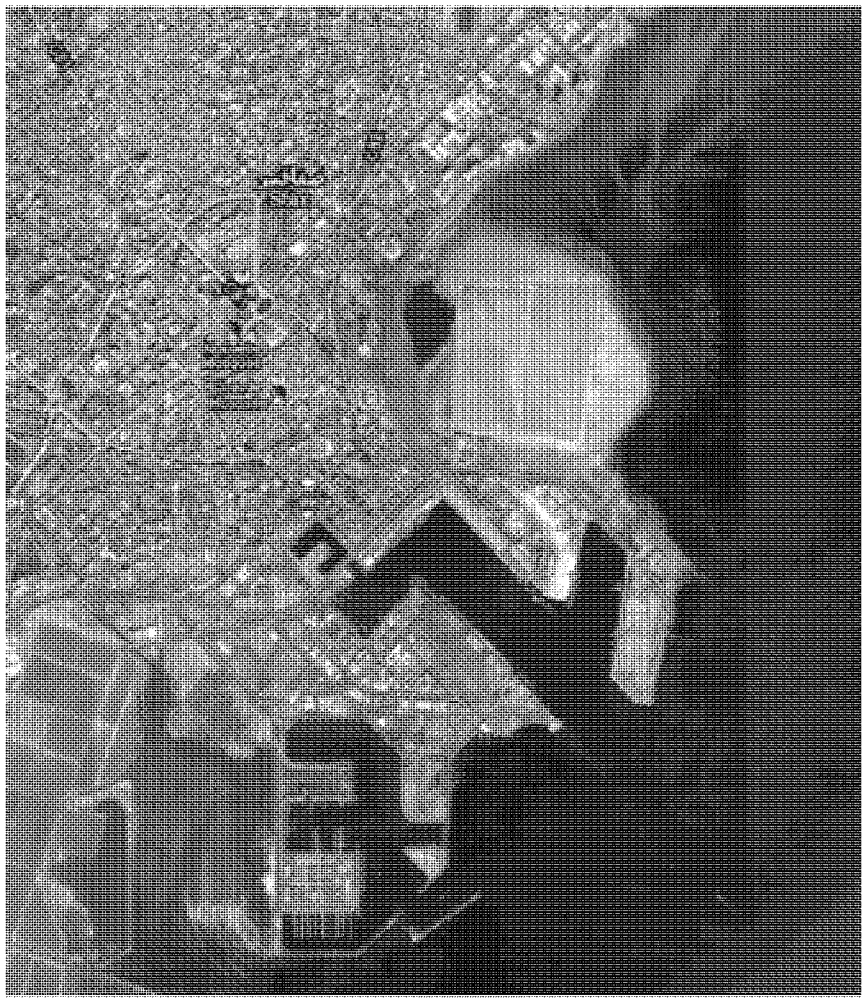

FIG. II–1. Satellite image of the Sfax phosphogypsum stack, harbour and town before the start of remediation work.

II–4. OBJECTIVE OF THE REMEDIATION PROJECT

The Taparura project at the Sfax site was divided into two main phases:

(i) Identification and remediation of the contaminated areas and recovery of land from the sea;
(ii) Development of the area and construction of a new urban centre.

ED_005285_00000684-00286

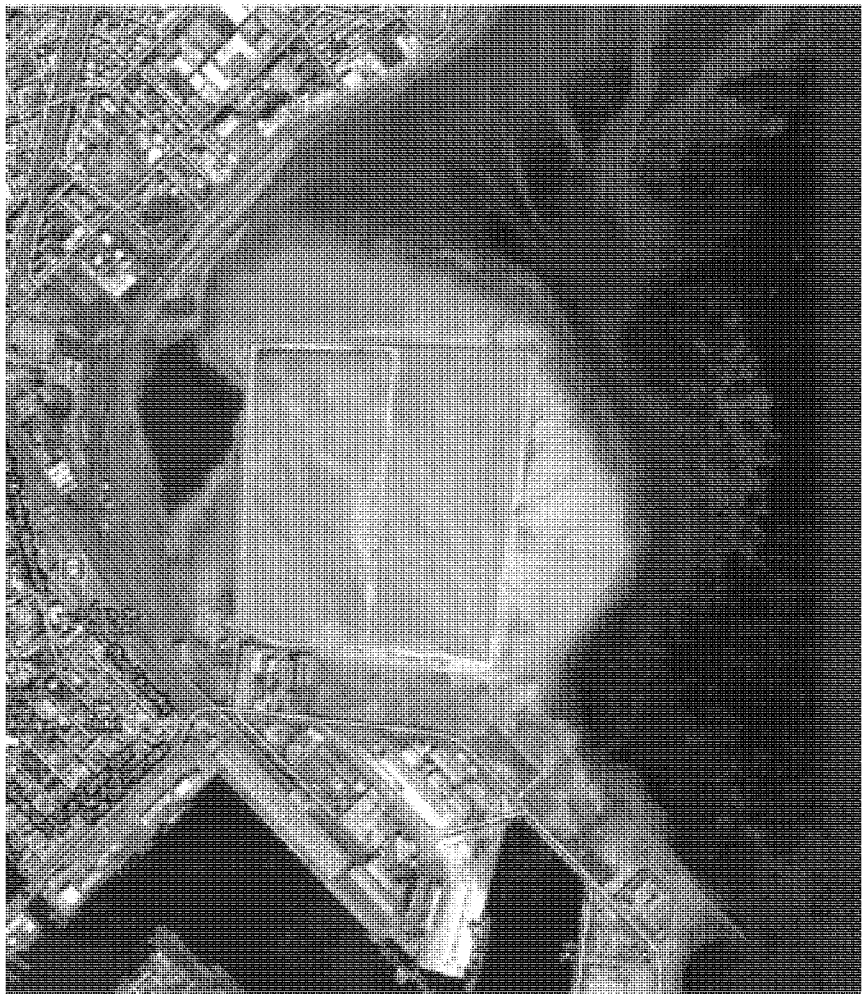

FIG. II–2. Enlarged view of the Sfax phosphogypsum stack before the start of remediation work.

The project was initiated to remove the contaminated materials on the land and in the sea, to consolidate these residues into a designed central containment, to restore the beach facilities close to the town and to reclaim additional land from the sea for urban expansion and tourism. Remediation work on the project began in April 2006 and was carried out over a period of 28 months. The first project phase, involving the removal of contaminated material from the sea and on land, was completed by 2008. The recovered contaminated material was consolidated into an engineered structure and a cover layer was subsequently

ED_005285_00000684-00287

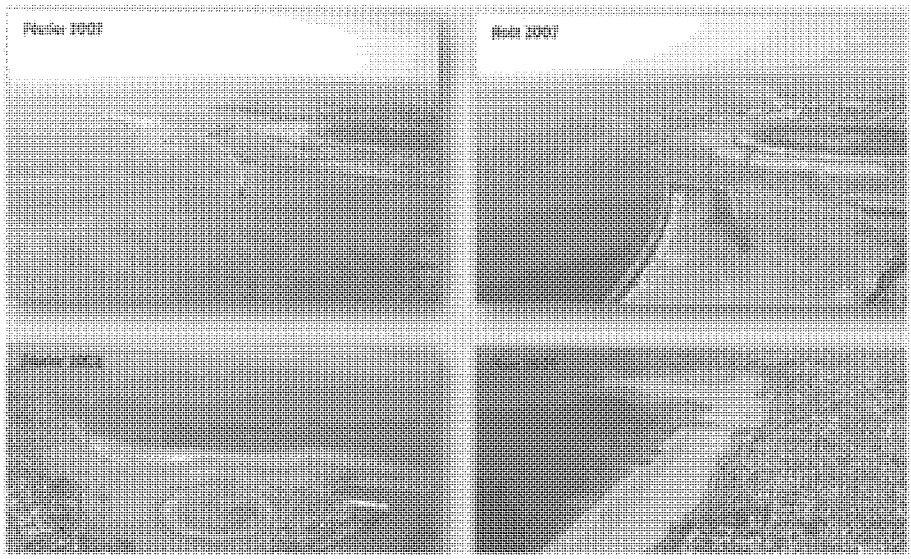

FIG. II–3. Various stages of progress with the remediation project.

added. Revegetation of the cover layer began in 2009. The project entered a two year guarantee period in June 2009, during which the remediated area was inspected and evaluated, with a variety of monitoring programmes (including radiation monitoring) being implemented. Aerial views of the site at various stages of project implementation are shown in Fig. II–3.

II–5. PROJECT MANAGEMENT

Project management was carried out by an autonomous government company Société d'Études et d'Aménagement des Côtes Nord de la Ville de Sfax under the supervision of the Ministry for Infrastructure and Housing. The work of the project was performed by a consortium of specialist companies from Belgium, France, Netherlands and Tunisia. The project, which cost €75 million, was funded through taxes and through loans from the European Investment Bank and financial institutions in Belgium and France.

II–6. DEVELOPMENT OF THE REMEDIATION PLAN

Several comprehensive studies were carried out to characterize the site and to determine the extent of the polluted areas and the quantities of materials to be

ED_005285_00000684-00288

remediated and contained on-site [II–5 to II–7]. The polluted area was assessed on the land and in the shallow sea surrounding the phosphogypsum stack. The monitoring focused on a number of key heavy metals (nickel, copper, cadmium, lead and chromium) and arsenic. The pollutant reference levels used to define the area requiring remediation were derived from Dutch standards on environmental remediation and were related to ecological risk criteria.

Once the extent of the polluted areas and the quantities of contaminants had been defined, the project engineers investigated the remediation options and the technologies required to complete the project. A clear priority was to minimize the contaminated area, which required the removal of significant quantities of solids from land and sea. Another priority was the long term physical stability of the containment and the design technology required to minimize the transport of pollutants from the containment into the surrounding groundwater. The design studies considered a number of long term aspects, such as the physical integrity of the structure and the site, hydrological aspects, the potential for floods and coastal erosion.

The option selected involved excavating the contaminated material (from both land and sea) and, after dewatering, incorporating it into the original phosphogypsum stack. Work carried out on the stack included the reshaping of the slopes, the installation of a vertical barrier around the perimeter in order to create a stable confined area, the installation of a cover layer of uncontaminated sand and the application of a new topsoil layer.

II–7. MOVEMENT OF MATERIAL

Approximately 1.7 million m^3 of various materials were excavated on land, including approximately 1.25 million m^3 of phosphogypsum plaque that surrounded the original stack. The modification of the stack shape from a square to a circular geometry involved the movement of 0.787 million m^3 of material, while a further 0.465 million m^3 of contaminated sediment was dredged from the sea and incorporated into the stack. The use of specialized computer controlled geographic information system positioning technology was required to dredge the polluted material from the sea. The polluted materials were sampled before and after dredging to ensure that the required level of decontamination had been achieved. The wet polluted material was stockpiled and dewatered in a specially designated area on top of the existing stack.

Backfilling of the remediated areas and the creation of a new beach entailed the movement of approximately 8 million m^3 of material. It was necessary to dredge approximately 7 million t of sand from an unpolluted area approximately 20 km from the site using trailer suction hopper dredges. Coastal protection was

ED_005285_00000684-00289

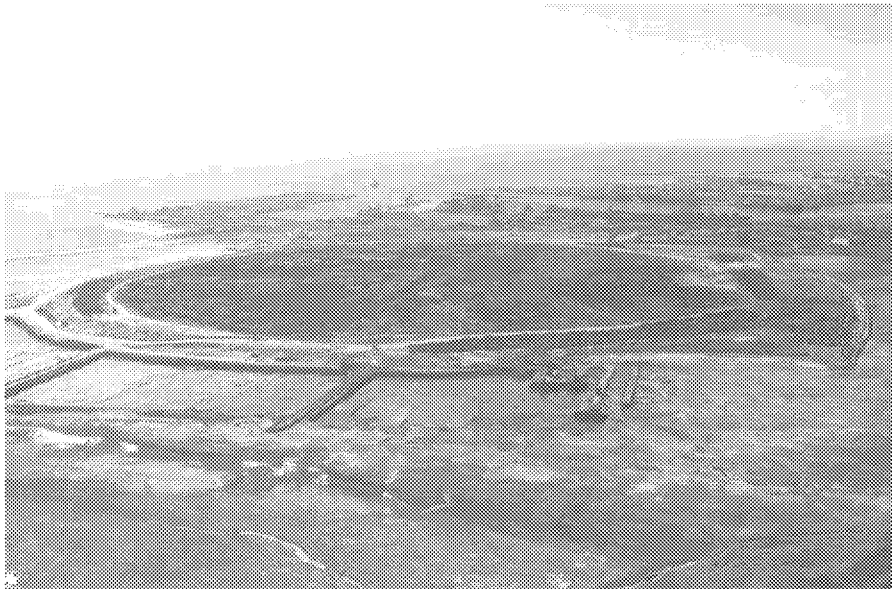

FIG. II–4. View of the site during the relocation of the plaque layers to the remediated stack.

enhanced by the construction of seven breakwaters around the site. The remediated site and containment were further protected by the construction of ring dykes and flood channels (requiring the excavation of approximately 0.45 million m^3 of material) to provide for flood control, to enable the dewatering of the consolidated phosphogypsum and to provide access to the remediated site.

Various activities involved in the movement of material are shown in Figs II–4 to II–7.

II–8. THE REMEDIATED STACK

The rectangular phosphogypsum stack was converted into a circular, terraced structure with a diameter of approximately 0.9 km, an area of 55 ha, a maximum height of 16 m and a 1 in 5 slope (see Fig. II–8). A layer of uncontaminated soil excavated from a site 20 km from Sfax was used to cap the 4 million t of material contained within the structure. The soil thickness varied from 0.8 m (on the top and terraces) to 2 m on the slopes. The design studies and modelling carried out prior to remediation indicated that a minimum thickness of 30 cm of uncontaminated cover was required to attenuate adequately the radon gas and gamma radiation emitted from the contained material. This criterion was

ED_005285_00000684-00290

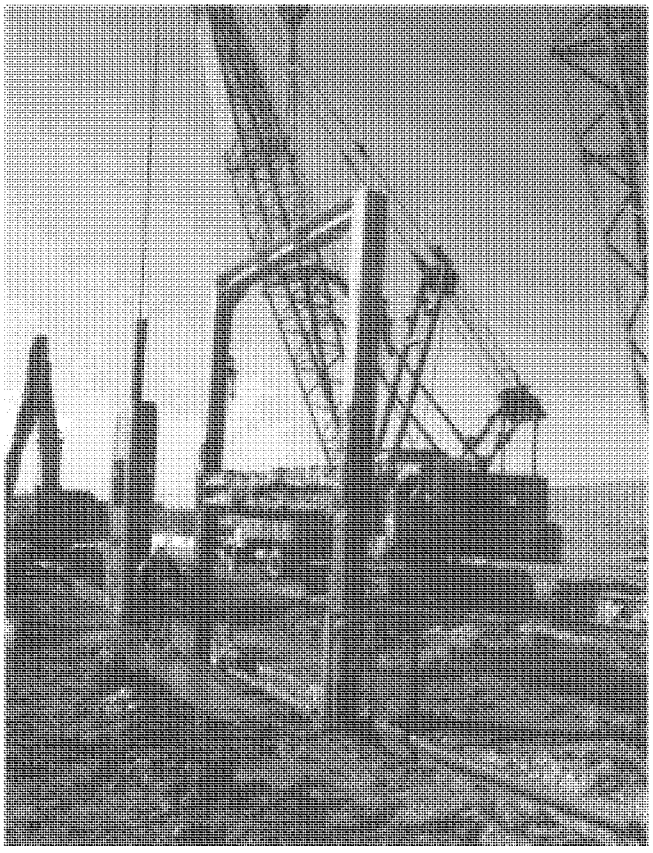

FIG. II–9. Construction of the concrete–HDPE water barrier around the remediated stack.

based on the assumption that permanent structures such as housing or offices would not be constructed on the top of the remediated stack.

The remediated stack is underlain by a sandy silt layer (the original beach). Beneath this, 7–9 m below the ground surface, is a thick layer of natural, consolidated red clay. The stack is surrounded by a barrier comprising vertical, interlocking, 3 mm thick high density polyethylene (HDPE) panels embedded in a bentonite and concrete foundation 2.8 km long, 0.6 m wide and 12 m deep (see Figs II–9 to II–11). This barrier prevents the lateral movement of polluted water from the remediated stack into the surrounding groundwater. The foundation of the circular barrier is embedded in the natural red clay layer to a depth of 2.5 m. The groundwater levels on either side of the lateral barrier are automatically monitored. The design of the remediated stack includes a number of boreholes for sampling and for measurement of groundwater levels.

ED_005285_00000684-00293

ED_005285_00000684-00294

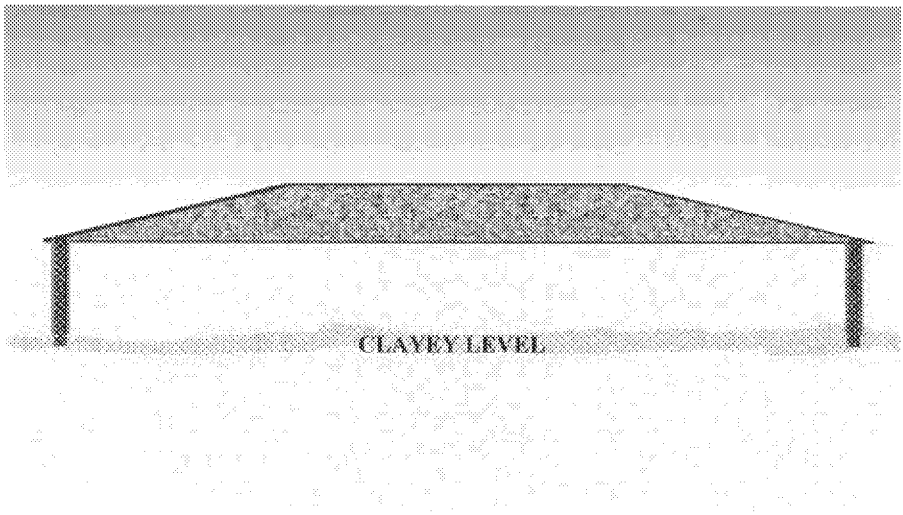

FIG. II–12. Simplified profile of the remediated stack, showing the underlying clay layer.

II–9. CONTROL OF SEEPAGE WATER

The clay layer beneath the remediated stack (see Fig. II–12) retards the downward movement of seepage water and purifies it by retaining a significant fraction of the heavy metal and radionuclide contents. The project engineers have estimated that the thickness of the clay is sufficient for this purification process to continue for several thousands of years.

The groundwater level below the remediated stack is constantly monitored by automatic systems. Water is pumped out automatically whenever the level approaches a height of 10 cm below that of the groundwater outside the water barrier. Seepage water beneath the remediated stack is collected and pumped through pipes into the flood control channel which then discharges into the harbour.

Prior to the remediation process (1994–1998), the seepage water had a high degree of acidity (pH4). Subsequently, the pH value rose towards neutrality and is now neutral. Analysis of the seepage water indicates that it contains elevated concentrations of phosphate and nitrate but very low levels of metal pollution.

ED_005285_00000684-00295

FIG. II–13. Stormwater channel.

II–10. CONTROL OF THE QUALITY OF SURFACE WATER AND GROUNDWATER

The average annual precipitation in the area is approximately 250 mm and from time to time the Sfax area is subject to intense rainfall. In 1984 there was a 1 in 100 year storm resulting in severe flooding of the area. This impact was considered in the design of the project and the flood control canals were built to protect the remediated area and handle the large amount of surface runoff water anticipated from this type of event. The surface runoff is collected and directed into the flood control channel which discharges into the harbour (see Fig. II–13).

II–11. FINAL OUTCOME OF THE PROJECT

Up to 2011, 6 km of coastline had been restored. The project involved the creation of 6 km of beach and 420 ha of land for urban development (260 ha of remediated land and 160 ha of land recovered from the sea). The beach and landfill restorations have provided space for new recreational activities (e.g. beaches, parks and sports grounds), an educational, health and museum infrastructure and social housing programmes. Monitoring of the remediated areas will continue.

ED_005285_00000684-00296

II–12. COMMUNICATION WITH THE PUBLIC

Communication with the public and stakeholder groups (e.g. individuals, community groups, regulatory bodies, universities and news media) was addressed at all stages of the project through a variety of mechanisms such as meetings, workshops, the internet, brochures and media communications. Throughout the project, the Centre Nationale de Radioprotection played a prominent role in addressing concerns about radiation issues.

II–13. RADIOLOGICAL SURVEYS AND ASSESSMENTS

The goal of remediation activities, such as those conducted as part of the Taparura project, is the timely and progressive reduction of the hazard and, eventually, if possible, the removal of regulatory control from the area without restrictions on future use [II–8, II–9]. In terms of IAEA safety standards, the remediation process should:

(a) Reduce the doses received by exposed individuals or groups of individuals;
(b) Avert doses to individuals or groups of individuals that are likely to arise in the future;
(c) Prevent or reduce environmental impacts from the radionuclides present in the contaminated area.

Reductions in the doses received by individuals and the amelioration of environmental impacts can be achieved by actions applied to the source of contamination (e.g. isolation) or by actions to remove the source, to modify the exposure pathways or to reduce the numbers of individuals or other receptors exposed to radiation from the source.

From 1998 onwards, several comprehensive radiological surveys were carried out prior to, during and after the rehabilitation work to assess occupational and public exposures [II–10] to [II–16]. In addition, gamma radiation surveys were conducted to identify and to assess the contaminated areas. The surveys were conducted using portable instruments, fixed monitoring stations and integrating devices (thermoluminescent dosimeters and track etch devices) for gamma radiation, indoor and outdoor radon, radon progeny and airborne dust. After evaluation of the initial radiological assessments, the Centre Nationale de Radioprotection defined a level of public exposure of less than 1 mSv/a above background levels for the future use of the remediated site, which was in line with international recommendations and standards at that time [II–17] to [II–19].

ED_005285_00000684-00297

The radiological assessments have demonstrated that, through the Taparura project, a reduction in the doses received by members of the public has been achieved by concentrating and containing the phosphogypsum residue in a central containment and backfilling the remediated areas with uncontaminated materials. The source is now confined to a small area of the site and the design of the remediated stack ensures that the migration of radioactivity into the environment remains within acceptable levels.

This Safety Report is a compilation of detailed information on the processes and materials used in the phosphate industry and on the radiological considerations that need to be taken into account by the regulatory body when determining the nature and extent of radiation protection measures. It has been developed as part of the IAEA's programme on the application of its safety standards in the fields of radiation, transport and waste safety. The information provided will assist in the implementation of a graded approach to regulation. This Safety Report provides information on expected radionuclide concentrations, exposure levels and the most appropriate regulatory approach for the phosphate industry, including mining and beneficiation of phosphate ore, phosphoric acid production, phosphogypsum and the utilization of rare earth phosphate residues.

Subject: For Review | Draft Subpart R (TFI) Webpage Language

Jess,

Attached is the draft Subpart R webpage language I am proposing. This includes a small section related to the TFI application. Joe has reviewed the draft and had minimal comments. I did not hear back from Jon today.

Ex. 5 Deliberative Process (DP)

Please let me know if you have any questions, and as always, I would appreciate any comments that you have on the draft webpage.

Thanks!
Stefanie

Jess,

Thanks for touching base. Here's where I stand with TFI. Support needed from you is noted below.

Can you both - drop me a note letting me know what actions you are currently taking of TFI. I just want to be able to report out accurately to Rick at my general tomorrow.

Ray - I just called to make sure you have everything you need (including someone working with you) on the TFI FR.

Stefanie - Is there anything you need from me?

Subject: Media Inquiry from Center for Biological Diversity: DDL COB today.
Importance: High

Dear Dan, Jon, and Tom:

The Center for Biological Diversity just sent this question in via the Press Office. Do you think we could provide an answer by COB today? I tried to draft an answer based on the Subpart R website text and our previously approved press answers, but it needs your input and approval. I'll be in our Center meeting starting at 2.

Question:

The last time it was evaluated for use in roads, the EPA found that the gypsum in FL was to radioactive for that use. (http://www.fipr.state.fl.us/about-us/phosphate-primer/phosphogypsum-and-the-epa-ban/). Without seeing the EPA's analysis (assuming there is one), I can't imagine what has changed, except the agency's tolerance for which and how many people get sick or die as a result of exposure.

Subject: RE: Approval of Request for Other Use of Phosphogypsum

It would just save them some time searching, if they don't already have them. You can provide our website link, although it doesn't look like the technical review is posted yet (Tony, is that right?). As of about 8:30, the docket wasn't showing anything other than the FR notice. But the technical review will be on the website and the docket today.

Subject: FW: Approval of Request for Other Use of Phosphogypsum

Here's what I sent ASTSWMO. Kerry Callahan is the ASTSWMO staff person we deal with for the Radiation Task Force, which is under the Materials Management Subcommittee. Feel free to edit as appropriate to make it CRCPD-specific.

I'd suggest having Charlene send anything to the regions. We did have a call yesterday and gave them an overview, and I think they might have the website.

From: Schultheisz, Daniel
Sent: Tuesday, October 20, 2020 8:29 AM
To: Kerry Callahan <KerryC@astswmo.org>
Subject: Approval of Request for Other Use of Phosphogypsum

Kerry:

You may have heard something about this, but I wanted to let you know that on October 14 EPA approved a request by The Fertilizer Institute (TFI) for use of phosphogypsum in government road construction projects. This approval is granted under the Clean Air Act and the provisions in 40 CFR 61.206, which allow EPA to approve other uses of phosphogypsum if they can be demonstrated to be at least as protective as keeping the material in a stack, which is the designated management method.

This approval is subject to terms and conditions, and we are not aware of any such projects under consideration at this time. A government agency proposing to use phosphogypsum in this manner would have to submit additional information to EPA and provide an opportunity for the public to review the proposal and documents related to this approval, including the risk assessment submitted by TFI. A key condition is that the road not be abandoned or converted for non-road uses, unless additional risk analyses are conducted and EPA is notified.

I thought this action would be of interest to the Materials Management Subcommittee, as states contemplating such use may have to conduct their own analyses to approve any such projects. EPA's approval is strictly limited to the Clean Air Act, and does not relieve TFI or end users of the responsibility to comply with any other applicable laws or regulations.

Attached are the approval letter and the Federal Register notice, which was published today. You can find more information at https://www.epa.gov/radiation/subpart-r-national-emission-standards-radon-emissions-phosphogypsum-stacks. The official docket for this action can be accessed through www.regulations.gov, search for Docket No. EPA-HQ-OAR-2020-0442.

Please let me know if you have any questions. Thanks.

Dan

Lee and Jon,

Good morning. I hope this finds you both well.

Attached is a updated version of the PG petition, response to the EPA questions on the risk assessment posed in January, response to the questions on the reclaimer scenario, and other assorted supporting appendices, some of which you have already seen. Not attached are Appendices 1 and 2, which accompanied the submittal in October 2018. I would be happy to resend these to your attention, if so desired.

Please confirm that you received these files (9 in all).

I will reach out early next week to discuss next steps in the petition review process and the potential need for a conference call.

Regards,
Andy

CONTENTS

This Petition and supporting risk analysis were developed by reviewing the "Applying to EPA for Approval of Other Uses of Phosphogypsum: Preparing and Submitting a Complete Petition under 40 CFR 61.206, A Workbook" (EPA PG Workbook) and prior petitions, and through a series of working meetings with EPA staff to obtain EPA input and direction on key elements of the analysis. Throughout this process, the methodologies and technical issues utilized in the technical evaluations were informed by EPA's feedback.

This Petition includes the following sections:

Section	Description
Preamble	Key Definitions
I	Overview
II	Petition Request and Legal Review Process
III	Regulatory History and Recent Developments
IV	Summary of Supporting Scientific Information
V	Application of Risk Management Factors to use of PG in road construction
Attachment A	Reference Road Construction Specifications

This Petition is supported by the following information:

Appendix	Description
Appendix 1	Summary of the Risk Assessment and Metals Screening Report (same as October 2019 Petition submission)
Appendix 2	Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum (same as October 2019 Petition submission)
Appendix 3	Human Health Risk Screening for Metals and Metalloids
Appendix 4	4a: Response to EPA Comments on January 16, 2020 and 4b: Responses to Second Set of USEPA Questions on March 6, 2020 – Reclaimer
Appendix 5	Report on recent measurements of PG radioactivity level in U.S. stacks
Appendix 6	Policy Navigation Group, Economic Analysis of Phosphogypsum Reuse (December 2019)
Appendix 7	Location of PG stacks (mailing address for the Petitioners is the TFI address on the Petition cover and the addresses in Appendix 7)

Appendix 8	Other documents being submitted for the administrative record

ED_005285_00000744-00003

DEFINITION OF KEY TERMS

The basic concepts relevant to this Petition are:

Dose: Dose measures the amount of radiation absorbed by a person. The terms radiation absorbed dose (rad) and gray (Gy) describe measurements of the absorbed dose.

1 gray (Gy) is equivalent to 100 rad; 1 rad = 0.01 Gy

Dose equivalent adjusts the absorbed dose to include the relative medical effects of gamma rays, alpha or beta particles, x-rays, or neutrons, e.g., the effects of alpha and neutron radiation are more damaging to the human body than gamma radiation.

The dose equivalent is measured in rems (roentgen equivalent man) or 1/1000th of a rem (millirem or mrem). A rem for each type of radiation is equal to the absorbed dose (in rads) times a quality factor that reflects the fact that some types of radiation cause more damage than others [see "Units of Radiation Dose," 10 CFR § 20.1004]. The scientific community is shifting to use the nomenclature developed for the international system unit, so the term sievert (Sv) is often used.

1 rem = 0.01 sievert (Sv); 1 sievert (Sv) = 100 rem; 1 millisievert (mSv) = 0.1 rem or 100 mrem.
100 rem is equivalent to 1 Sv or 0.1 rem (or 100 mrem) equals 1 mSv.

Effective Dose is the tissue (organs) weighted sum of equivalent doses summed over all specified tissues and organs where each tissue is assigned its own tissue weighting factor (written as w_T). The tissue weighting factor is intended to represent the relative contribution of that tissue or organ to the total health detriment resulting from unform irradiation of the whole body.

Government Road Project for purposes of this Petition, means a road construction or repair project that is authorized by federal, state or local governments consistent with applicable Federal Highway or state Departments of Transportation (DOT) standards and specifications, including public works departments that have adopted the state DOT standards and specifications or developed such standards in consultation with state regulatory authorities (such as the Federal Highway Administration (FHWA) regulations and guidance, State Department of Transportation (DOT), American Association of State Highway (AASHTO), American Society for Testing and Materials (ASTM)) or other generally accepted specifications for road building.

Petition Maximum average radium (226) concentration limit: The Petition requests that EPA approve use of PG containing an average radium (226) concentration up to 35 pCi/g in road construction. The 3 in 10,000 risk level (EPA's safe level) corresponds to an average radium (226) concentration of 148 pCi/g. Thus, this proposed limit is presumptively safe.

The requested limit of 35 pCi/g is consistent with the 2019 stack sampling and with prior sampling conducted by EPA. Specifically, the broad sampling data demonstrates that PG taken from the stacks is not expected to exceed that limit. As background, the risk assessment used 27 pCi/g for its baseline evaluation (this correlates to the international standard of 1Bq) and extrapolated to reach conclusions for 35 Ci/g (see Nominal radium 226 concentration definition below). An average radium (226) concentration of 35 pCi/g for PG used in road construction materials accounts for potential variability (~30 percent) observed in past testing and during implementation of road construction.

Nominal radium (226) concentration: The radium (226) concentration level utilized in the underlying Risk Assessment filed with the petition (the Petition's Risk Assessment) is a nominal radium (226) concentration of 27 pCi /g. This particular nominal concentration was chosen so that the submission contained a calculated risk using RME, which corresponds to a "nominal" concentration of radium (226). Since the relationship of radium (226) concentration in PG to risk is proportional, the risk from using PG containing any other concentration of radium (226) in road construction can be calculated from the nominal concentration.

Radioactivity is a measure of the amount of gamma rays, alpha or beta particles, x-rays, or neutrons that disintegrate from a gram of the substance being measured (in our situation, in each gram of PG). The amount of radioactivity in a gram of a substance is measured in curies (Ci) or becquerels (Bq). One curie is 3.7×10^{10}

ED_005285_00000744-00004

radioactive decays per second, roughly the amount of decays that occur in 1 gram of radium per second. A Becquerel is one disintegration per second. Historically, scientists originally used units of Ci. The International System of Units (ISU) now uses Bq.

A picocurie (pCi) is one-trillionth of a curie.
1 Bq = 2.70 x 10^{-11} curies = 0.027 pCi

Many substances (often naturally occurring substances) are radioactive. Generally, the sources for this explanation include EPA, *Radiation Terms and Units*, *available at* https://www.epa.gov/radiation/radiation-terms-and-units; NRC, *available at* https://www.nrc.gov; MIT News, *Explained: rad, rem, sieverts, becquerels A guide to terminology about radiation exposure*, *available at* http://news.mit.edu/2011/explained-radioactivity-0328; National Aeronautics and Space Administration, *Radiation Math*, *available at* https://www.nasa.gov.

Radium (226) concentration level that corresponds to 3 in 10,000 risk management level that EPA has designated as safe. The risk assessment performed for the Petition demonstrates that PG containing a radium (226) concentration of 148 pCi/g presents a risk of 3 in 10,000 (EPA's safe level).

Reasonable Maximum Exposure: An estimate of a conservative exposure case, well above the average case, that is still within the range of possible exposures.

Risk: The regulatory risk assessment process converts a dose equivalent (in mrem) into an upper bound risk (or probability) of developing fatal cancers. It is based on a regulatory assumption that the dose equivalent may cause harmful effects and as the magnitude of this dose increases or decreases, the risk increases or decreases, in direct proportion, respectively, i.e., linearly (e.g., if the dose is halved, the calculated risk is halved). The risk assessment performed for this Petition concludes that an effective dose of 600 millirem corresponds to a risk of 3 in 10,000 (i.e., if all of the protective assumptions are valid, 3 in 10,000 people may develop a fatal cancer). The actual risk is likely to be lower.

ED_005285_00000744-00005

I. OVERVIEW

A. INTRODUCTION

Approximately 46 million tons of phosphogypsum (PG) is produced annually in the U.S. as a byproduct of the phosphate fertilizer production process.[1] For decades, the majority of PG has been placed in large engineered gypstacks, instead of using the material in various applications.

Internationally, PG is used in road construction, concrete and building material production, agriculture, mine restoration, marine applications and for daily landfill cover. Scientific studies completed in both the U.S. and internationally support these beneficial uses of PG. The studies demonstrate use of PG in numerous applications is protective of human health and the environment and, at least as protective of human health as storage of PG in a stack.

This Petition, submitted by The Fertilizer Institute[2] (TFI), requests approval for PG use in government road construction projects. The request is submitted pursuant to the United States Environmental Protection Agency's (EPA) rule governing the distribution and use of phosphogypsum for purposes other than disposal in a stack. See 40 CFR §61.206.[3] Under this provision, a request for a proposed use with supporting information[4] must be submitted to EPA. The request is followed by EPA review and a determination allowing or rejecting the proposed use. EPA may make a determination granting the request if the proposed use is at least as protective of public health, in the short and long term, as disposal in a stack. If EPA makes a determination approving the proposed use, specific information in connection with the projects conducted must be certified and maintained for five years. For example, each time PG is removed from the stack for the approved use, the stack owner/operator must certify the identity and location of the user, the quantity of PG provided, a description of the end use, and the average radium 226 concentration.

This Petition should be approved by EPA because:

[4] The supporting information includes: petitioner identity, description of the proposed use, street location and mailing address of the facility where use, handling or processing of PG occurs, quantity of PG to be used, average radium (226) concentration in PG that will be used, measures to prevent PG releases to the environment, risk associated with the proposed use, including ultimate disposition, management of unused PG, requestor signature.

ED_005285_00000744-00006

- The risk of radiation exposure from use of PG in road construction is low, well within EPA's 3 in 10,000 lifetime cancer risk determined to be safe and well below natural background exposure levels.

- Demand for available, cost-effective road construction materials is high. This is particularly true where other materials widely used in road construction, such as coal ash, are anticipated to become scarce and more expensive due to new regulatory contraints on production and storage.[5] Radiation from PG is similar or less than other materials currently used in road construction.

- Use of PG in road construction has environmental and societal benefits, reducing the amount of material required to be stored in stacks (and potentially eliminating existing stacks over the longer term).

- There are other economic and societal benefits (discussed in more detail in Appendix 6).

B. BACKGROUND

PG is a byproduct of the phosphate fertilizer production process. At a typical U.S. facility, approximately five tons of PG are generated per ton of phosphoric acid produced. Prior to 1989, PG was used in various applications (including, among other uses, in the construction of roads and in agriculture).

NESHAP Regulations Governing PG. Thirty years ago, EPA restricted the use of PG based on the estimated risk from exposure to naturally occurring radioactive material (NORM) in the material. These restrictions are set forth in the regulations governing the management of PG in EPA's National Emission Standards for Hazardous Air Pollutants (NESHAP), Subpart R of title 40 of the Code of Federal Regulations. Subpart R requires that, with very limited exceptions for agricultural use and indoor research, PG must be placed in engineered above ground impoundments (commonly referred to as "gypstacks").[6]

With respect to the stacking exceptions, Section 61.206(a) allows removal of PG from stacks without prior approval[7] for: (i) outdoor agricultural use of PG containing an average radium-226 concentration not exceeding 10 picocuries per gram (pCi/g) (§61.204) and (ii) indoor research and development not to exceed 7,000 pounds (§61.205).[8] These uses are self-implementing; no

[6] 40 CFR §§ 61.200 - 201.

[7] EPA later approved placement of PG as landfill cover in a test cell to determine if PG can be used more broadly as a landfill cover. Letter from Jeffrey R. Holmstead, Assistant Administrator of the Office of Air and Radiation, to Michael Lloyd, Jr., Research Director Chemical Processing, Re: FIPR Petition (December 22, 2004) (Holmstead FIPR Letter).

[8] 40 CFR §§ 61.204 - 61.205.

additional authorization is required. However, the stack owner and the user must comply with specific reporting and record keeping requirements.[9]

Any other uses must first be approved by the EPA Assistant Administrator for Air and Radiation. Under Section 61.206(c), the request may be approved if the proposed use is determined to be at least as protective of public health, in both the short term and the long term, as disposal of PG in a stack.

Post-NESHAP Developments. Since the NESHAP was promulgated decades ago there have been a number of developments in various realms that support broader use of PG.

- **New Scientific Information**. New data are available on the average level of radioactivity in the PG. There is also a better understanding in the scientific community concerning radiation protection and management related to PG use. Studies have been completed in the U.S. and internationally supporting expanded beneficial use of residual material from manufacture of fertilizer; these studies demonstrate protectiveness of human health and the environment.

- **Risk Assessment and Policy Updates**. Risk assessment approaches have progressed based on experience, analytical advances, and evolving policies since the 1980s.

  For example, EPA's prior assessments of the risk from use of PG in road construction (e.g., in the 1989 regulations and the EPA 1992 Background Information Document) did not evaluate the potential radiation risk from every possible road design. Rather, EPA recognized that it is not necessary to calculate every potential exposure. It is appropriate and consistent with EPA policy to examine risk by utilizing a "reasonable maximum exposure" approach (RME). According to EPA, the RME is "a conservative exposure case, (i.e., well above the average case) that is still within the range of possible exposures."[10] EPA guidance states that the assessor may derive a high-end estimate of exposure by using maximum or near maximum values for one or more sensitive exposure

[9] 40 CFR §§ 61.206 – 209. Approvals under §61.206(b) require compliance with sampling procedures (§61.207), certification requirements (§61.208), and records rquirements (§61.209(c)), unless the Assistant Administrator decides to waive or modify the record keeping requirements.

[10] EPA, Risk Assessment Guidance for Superfund: Volume III - Part A, Process for Conducting Probabilistic Risk Assessment, EPA 540-R-02-002, 7-1 (2001), *available at* https://www.epa.gov/sites/production/files/2015-09/documents/rags3adt_complete.pdf. (EPA Risk Assessment Guidance for Superfund).

See also Interstate Technology Regulatory Council (ITRC), Decision Making at Contaminated Sites, Issues and Options in Human Health Risk Assessment, 6.1.1 (2015), *available at* https://www.itrcweb.org/risk-3/Default.htm#6.%20Exposure%20Assessment.htm#6.1__Determining_Appropriate_Exposure_Factors%3FTocPath%3D6.%2520Exposure%2520Assessment%7C6.1%2520%2520Determining%2520Appropriate%2520Exposure%2520Factors%2520%7C_____0 (ITRC, Decision Making at Contaminated Sites) (citing EPA Guidance, which states that "[t]he RME . . . can be defined as 'the maximum exposure that is reasonably expected to occur within a potentially exposed population'").

ED_005285_00000744-00008

factors, leaving others at their mean value.[11] Therefore, RME is not the worst-case exposure and a worst-case exposure analysis was not required by EPA.

RME provides the exposure used to calculate the maximum individual risk (MIR). As long as the risk from RME does not exceed 3 in 10,000, the exposure is "safe" (see discussion of EPA's policy on the safe risk level for PG (Section IV, below)). By definition, if the risk from a RME exposure for construction workers, truck drivers, road users, and residents is below 3 in 10,000 and, therefore, safe, all other exposures to workers, truck drivers, road users, and residents present even less risk (and in many cases, the risk is much less than 3 in 10,000).

Additionally, there has been an increased awareness of product lifecycles and sustainability. Accordingly, current EPA policies encourage use and recovery of high-volume, low-risk waste. This includes increased emphasis on understanding product lifecycles and sustainability.

- **Regulatory.** It has become apparent that the current requirement to obtain regulatory approval for each and every application of a new use is unwieldy and slows the process of implementing new uses without providing additional protection of human health (i.e., use of updated scientific and risk assessment assumptions demonstrate that road use is safe). As a result, the past interpretations impede innovation and economic efficiencies. The fact that no PG use requests have been submitted in almost 30 years (except for a landfill cover test cell) illustrates this point.

- **Commercial Economics and International Use Precedents.** The economics of gypstacks have changed. The cost to stack and manage gypstacks has increased substantially beyond original expectations. These costs adversely affect the ability of the U.S. fertilizer industry to compete internationally, where PG may be used.

  PG is used in many countries outside the U.S. in agriculture, mine restoration, building materials, marine applications, daily landfill cover, and for road construction. More than a dozen beneficial uses have been analyzed worldwide, resulting in significant, successful PG use applications in at least 21 countries.[12]

- **Public Perception.** Perceptions of gypstacks have changed. EPA's 1989 final rule did not anticipate the range of public sentiment regarding the long term presence of gypstacks. Public pressure to cease this practice is growing.

This section reviews international and U.S. roads constructed with PG. Other chapters address other uses.

Beneficial Use of PG in Government Road Projects. Based on the developments and framework described above, TFI submits this Petition seeking approval of PG for use in government road projects.[13] The scope of this request is described below.

- **Description.** A paved road consists of a solid surface or top layer that is typically asphalt, concrete, or some other material or mixture approved for use as pavement. The road base is a supporting layer of material approximately 0.25 m thick beneath the surface/pavement and underlying the road base is the sub-grade (as shown in Figure 1). The proposal is for approval of use of PG as road base or surface pavement.

- **Design.** PG may be used as road base or surface pavement when mixed with other materials such as soil, sand or aggregate or in the surface pavement. This Petition requests approval for use of up to (i) 2.5% PG in surface pavement and (ii) 50% PG in road base. This mixture is based on a design of up to equal amounts of PG and soil in roadbed.[14] Using a ratio of 50% or less PG mix in road base, approximately 4000 tons of PG per lane-mile would be used in road base and less than 100 tons per lane-mile would be used in concrete pavement (Appendix 4a: Response to EPA Comments on January 16, 2020).

  These ratios are supported by prior technical evaluations. For example, various ratios of PG to soil were studied (from 100% sand to 100% PG) and all mixes had California Bearing Ratio values higher than sand or PG separately. Studies of the road containing PG in Polk County Florida found similar results (Appendix 4a: Response to EPA Comments on January 16, 2020).

- **Exposure analysis.** The road design features analyzed in the Petition (Appendix 2),[15] the Metals Screening Report (Appendix 3), and Response to EPA Comments on January 16, 2020 (Appendix 4a)) were determined to represent RME for all road designs, regardless of the size of the road. That is, the radioactivity levels emitted from the road in using these design assumptions were RME assumptions and did not exceed 3 in 10,000 (Appendix 4a). Thus, assuming the RME calculation is appropriate, the radioactivity exposure risk associated with all other road designs is less than 3 in 10,000, the EPA determined acceptable risk level.

  EPA's 1992 BID risk assessment approved the use of PG for agricultural soil amendments as safe.[16] The EPA 1992 BID risk assessment assumed biennial applications of PG over 100 years on agricultural soil (with the PG containing a radium

---

[13] The Petition for PG use in road construction covers only paved roads that meet the definition of "Government Road Project" included in this Petition. Unpaved roads have not been evaluated and are not within the request.

[14] This is an upper bound because industry practice recommends similar ratios or less and EPA's 1992 risk assessment used 33.3 percent PG to 66.6 percent soil (see Appendix 2).

[15] EPA, Potential Uses of Phosphogypsum and Associated Risks, Background Information Document, 402 R92 002, 4 26 4 35 (May 1992), *available at* https://www.epa.gov/sites/production/files/2015-07/documents/0000055v.pdf (EPA 1992 BID).

[16] *Id.* at 4-26.

ED_005285_00000744-00010

(226) concentration of 10 pCi/g) and no cover.[17] EPA assumed that approximately 2,700 pounds of PG per acre is "spread over a field and diluted by mixing with the soil." [18]

Unlike PG in agricultural use, PG used in road base is mixed with soil (50% PG and 50% soil), application is one-time and not repeated, and there is no cumulative concentration of radium (226).

In each case, the risk is based on the exposure assumptions utilized. The radiation dose (and, therefore the risk) is a function of the average radium (226) in the road base (or cement), not the volume of PG used in a road application.

Figure 1 provides a conceptual view; municipal roads can vary in width and structure.

- **PG Users.** This Petition requests approval to use PG in ***government*** road construction projects. Thus, the authorized users of the PG would include federal, state and local Departments of Transportation (DOT) or Public Works (PW), and their contractors. Only these governmental agencies are authorized to commission governmental roadways.

- **Project Locations.** Given transportation costs, government PG road construction projects are expected to be located in states that are in sufficient proximity to the PG stacks (i.e., Florida, Georgia, North Carolina, Idaho, Louisiana) to make PG use economically viable. Appendix 7 provides the location of the PG stacks associated with TFI member operations.

- **Project Specifications.** TFI reviewed how similar materials used in road construction are managed to determine how PG would be handled, transported, stored and used in federal, state or local government road projects. PG would not be the first byproduct to be used in road construction (see below). Nor would it be the first byproduct for which road construction specifications were developed to substitute the use of a byproduct for other road building material. Government (particularly State) DOTs have considerable experience in this regard.

While there are distinctions between PG and coal ash, the regulation of coal ash by the states is analogous because the materials are excluded from federal regulation under the RCRA Bevill amendment (42 U.S.C. § 6921(b)(3)(A), Resource Recovery and Conservation Act § 3001(b)(3)(A)). Currently, according to EPA:

> [S]tate environmental agencies are primarily responsible for regulating beneficial use [of coal ash, because the] use of coal combustion residuals is currently excluded from federal regulation under EPA's May 2000 regulatory determination that the Bevill amendment applies to such uses. [and] [t]he April 2015 final … [coal combustion] disposal rule reaffirm[ed] EPA's Bevill determination.[19]

---

[17] *Id.*at 4-5 - 4-6.

[18] *Id.* at 4-5.

[19] EPA, Coal Ash Reuse, How is the Beneficial Use of Coal Ash Currently Regulated? (last updated July 15, 2019), *available at* https://www.epa.gov/coalash/coal-ash-reuse. Tecnically, the Bevill amendment applies to the type of

ED_005285_00000744-00011

Analogously, the use of PG is regulated by the Clean Air Act NESHAP regulatory program based on the radioactivity in PG, but otherwise is excluded from federal regulation under the RCRA Bevill amendment.

Government road projects are constructed in accordance with overarching Federal Highway Administration (FHWA) regulations and guidance, under the direct supervision of state Department of Transportation (DOT) requirements. "Because roadway location and design decisions affect the development of adjacent areas, it is important that environmental variables be given full consideration."[20] These specifications dictate how various materials may be used, based on strength and stiffness considerations, permeability, and stability, among other factors. [21] The FHWA released guidelines for use of coal fly ash and other materials (e.g., kiln dusts) in asphalt concrete, Portland cement concrete, stabilized base, flowable fill, and embankment or fill.[22]

Specifications are designed using various materials testing methods developed by these professional organizations, such as AASHTO and ASTM. Thus, since the RME were selected based on the road construction project meeting these design criteria, the risk assessment represents RME.

State Regulatory Programs. In addition to EPA's NESHAP determination, use of PG in road construction will be subject to state regulation and oversight. State regulatory programs developed for managing use of industrial by-products will apply as will state specifications for road construction.

For example, the Florida Department of Transportation's Standard Specifications For Road and Bridge Construction state that roads must: (a) "[p]rovide erosion control measures where work is accomplished in conjunction with the project, to prevent erosion, pollution of water, detrimental effects to public or private property adjacent to the project right-of-way and damage to work on the project;" (b) "not drive in, operate, or place construction equipment or materials in surface waters, wetlands, groundwater, or property beyond the project limits without permitted

---

waste, not just to the use. The quote describes EPA's application of the Bevill amendment in this particular use. From a broader perspective, it highlights the fact that state regulators have jurisdiction over many types of waste.

[20] Association of State Highway and Transportation Officials (AASHTO), A Policy on Geometric Design of Highways and Streets, 7th Ed., 2-95 (2018), *available at* https://store.transportation.org/item/collectiondetail/180?AspxAutoDetectCookieSupport=1 (The Green Book) (an online guidance that is over 1,000 pages). AASHTO is a nonprofit, nonpartisan association representing highway and transportation departments and a leader in setting technical standards for design, construction of highways and bridges, materials, and many other technical areas. Consideration of impacts on the environment are explicitly required to be considered. *Id.* at 1-2.

ED_005285_00000744-00012

authority for permanent or temporary impacts;" and (c) "not allow water that does not meet state water quality standards or does not meet the permitted criteria to exit the project limits."[23]

There are specifications for and policies encouraging the use of fly ash, slag, and/or other recycled material in roadways in Florida, North Carolina, Louisiana, and Idaho, among other states.[24] In Florida, industrial by-products are defined as:

> Materials that have a demonstrated recycling potential, can be feasibly recycled, and have been diverted or removed from the solid waste stream for sale, use, or reuse. The term does not include any materials that are defined as recovered materials, a mixed waste stream that is processed to removed recyclable materials; or materials the recycling or use of which is specifically addressed in [FDEP] rules, such as construction and demolition debris, ash residue, waste tires, used oil, and compost. Fla. Admin. Code 62-701.200(51).

Industrial by-products are regulated as solid waste unless otherwise exempted under Fla. Admin Code 62-701.200(51).

Florida is required to:

> Encourage recycling and resource recovery as a source of energy and materials. Fla. Stat. §403.704(6);

>
> Assist in and encourage, as much as possible, the development within the state of industries and commercial enterprises which are based on resource recovery, recycling, and reuse of solid waste. Fla. Stat. §403.704(7).[25]

Further, the Florida DOT is required to encourage the use of products and materials with recycled content in its road construction programs and to continually update its bid procedures and specifications to encourage the use of such products and materials, *see* Fla. Stat. §336.044(4). Therefore, once EPA authorizes use of PG in road construction, the Florida DOT will have a clear path under Florida law to consider whether its existing road specifications are adequate or if any modifications are warranted.

Similarly, North Carolina has design specification guidance.[26] Notably, North Carolina includes a policy "to aid in reduction of materials that become a part of our solid waste stream."[27]

In Idaho, using fly ash as an example, materials may be used only if provided by manufacturers approved by the state's Quality Assurance Program (QAP). Manufacturers not approved under the certification program require pre-approval before use.[28] The QAP mandates sampling be conducted by accredited labs, among other requirements. Idaho has recently passed a law that requires the development of a regulatory program for PG use.[29]

Louisiana's Solid Waste Management and Resource Recovery Law directs maximum practicable use of resource recovery procedures. [30] The Louisiana Solid Waste Regulations include Section 1105: Beneficial Use of Other Solid Wastes which allows owners of waste streams to request that the waste be designated for an approved beneficial use. The application process specifies much of the same information required under the NESHAP regulation 40 CFR 61.206(b), and indicates that, at least in Louisiana, prior to any use of PG in road construction, the state may be required to make a determination similar to EPA, including approval of a handling and storage plan. [31]

ED_005285_00000744-00014

The existence of these stringent state regulatory programs coupled with the need for a specific DOT specification for PG use in roadbuilding provide additional assurances that EPA's approval of PG use in road construction will ensure responsible handling and management of PG in road construction. Therefore, once EPA authorizes use of PG in road construction, the states will be able to make informed choices as to the most appropriate and cost-effective road construction material, while still ensuring the protection of the environment.

Public Health and Environmental Evaluation. The Petition is accompanied by a Radiological Risk Assessment (Appendix 2) and a Human Health Risk Screening for Metals and Metalloids (Appendix 3). The scope and approach to these analyses were developed based on the EPA PG Workbook, prior petitions, and a series of working meetings with EPA staff that provided the benefit of EPA input and direction on key elements of the analysis.

To assist in this evaluation, TFI members measured the radioactivity level in the PG from stacks.[32] Results reflect that average radiation levels from the composite samples taken from stacks do not exceed: (a) the nominal radium (226) concentration used in the risk analysis (i.e., 27 pCi/g) and (b) more importantly, the 148 pCi/g radium (226) concentration corresponds to the 3 in 10,000 risk management level that EPA has designated as safe (see Sections II(B), III(G), V, V(D)(3,4), below).

Key points of the Radiological Risk Assessment are provided in Attachment B. In summary, this assessment demonstrates that PG can be used safely for road construction for the following reasons:

Use of Reasonable Maximum Exposures (RME) Ensures Risk is Less than 3 in 10,000

All RMEs resulting from use of PG in road construction correspond to a risk of less than the 3 in 10,000 lifetime cancer risk (the risk level that EPA has determined to be safe for alternative PG uses and well below natural background exposure (see Summary Table 1, below, and the Petition's Risk Assessment summarizing the risks from each of the five exposure scenarios calculated for this Petition)). EPA staff clarified interest in more risk distribution information on how the risk varied with the "variation of the geometry of exposure" and with different exposure time frames (Appendix 4a: Response to EPA comments on January 16, 2020). The risk distribution is similar in each scenario with the the highest risk associated with the RME exposure scenario. Most actual exposures are less than those received by the RME and hence the associated risk would also be lower (Appendix 4a: Response to the EPA Question on January 16, 2020). For example, the risk is lower for workers who are not exposed for the same duration or as directly as the RME scenarios. The analysis also shows that the risks for the residential RME scenario are much lower than for the construction worker, truck driver, and road user. In each case, most of the exposed population have a dose that is lower than the RME dose (see Appendix 4a: Response to EPA Comments on January 16, 2020).

[32] A summary of this data was provided to EPA to support this Petition in a separate report, along with the location and address of each facility (Appendix 5).

ED_005285_00000744-00015

Table 1: Dose, Risk, and Background Summary for All RME Scenarios

Receptor	CSM	Exposure Duration (years)	Exposure Dose (mrem)	Estimated Cancer Risk	Background Dose from Exposure Duration (mrem)	Exposure Dose Percentage of Background Dose (%)
Reasonable Maximum Exposure Scenarios						
Road Construction Worker	PG in Road Base	5	110	0.5 in 10,000	1550	7%
Road User (Motorist/Bicyclist)	PG in Road Base & Surface	26	28	0.1 in 10,000	8060	0.3%
Truck Driver	PG-containing material for Road Base	5	93	0.5 in 10,000	1550	6%
Nearby Resident	PG in Road Base & Surface	26	16	0.08 in 10,000	8060	0.2%
Utility Worker	PG in Road Base	1	0.8	0.004 in 10,000	310	0.3%
	EPA Cancer Risk Management Goal		600	3 in 10,000	600	

Estimated cancer risk below this goal.

- The highest risk in the Petition's Risk Assessment was for the RME construction worker scenario --- 0.5 in 10,000 and the RME worker dose is 7% of the background dose for a worker at a road construction site not using PG (see Table 1, above, summarizing the risks from all exposure scenarios).

- The Response to the EPA Comments on January 16, 2020 expanded on the Risk Assessment by evaluating the uncertainty in each of these exposure scenarios and finding no significant increase even using the assumptions postulated in the EPA comments. In any case, the postulated assumptions were in excess of the RME and did not warrant a change in the risks in the Petition's Risk Assessment.

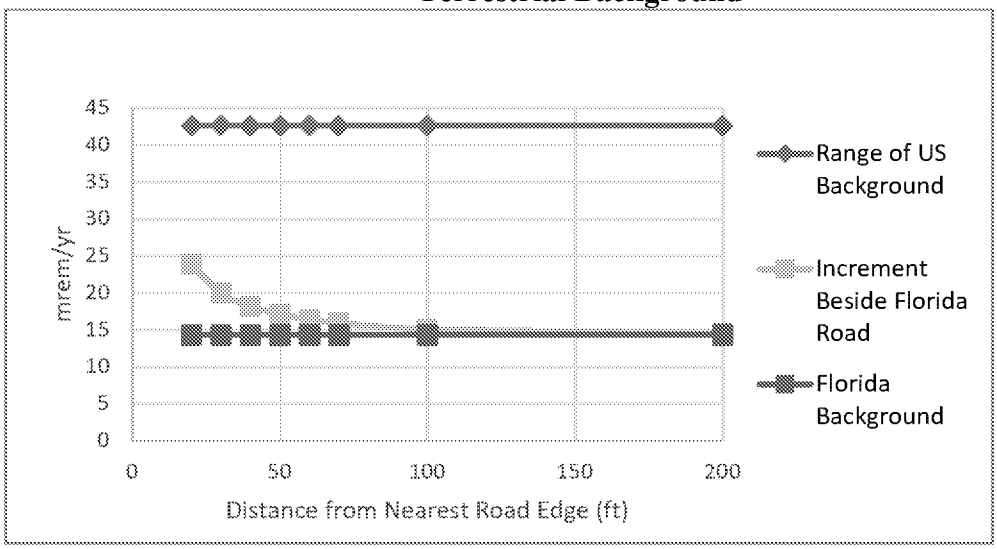
Risk Distribution Issues

Most of the exposed populations have a dose that is lower than the dose of the RME individual. For example, most road construction workers are exposed to a dose of less than 110 mrem, thus the risk is lower than 0.5 in 10,000 (still assuming that the radium (226) concentration is 27 pCi/g).

Residents directly adjacent to the road (the RME individual) are calculated to have a risk of 0.08 in 10,000, which is much lower than the RME construction worker. Additionally, the dose (16 mrem) is only 0.2% of the background radiation dose of the resident adjacent to a road not using PG. Thus, the incremental risk above background from a road containing PG is very low. Dose (and, therefore, risk) decreases substantially as distance from the edge of the PG road increases (see Figure 2 below). As a result, residents whose houses are not adjacent to the PG road have essentially no incremental dose and risk.

ED_005285_00000744-00016

Figure 2: Incremental External Gamma Dose with Distance Compared to Terrestrial Background



(From Response to EPA Questions on January 16, 2020)
N.B.: All natural background (as used in Table 1 is higher than the Terresterial background utilized in this Figure).

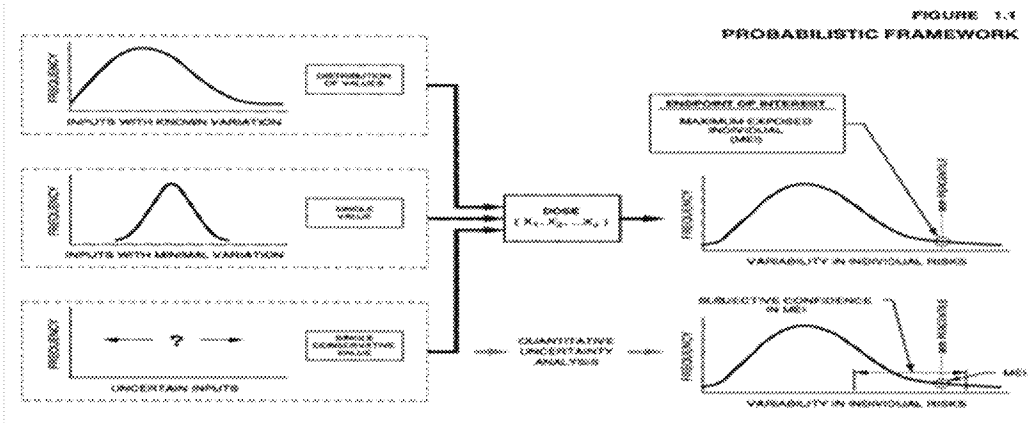
<u>Uncertainties in RME Selection, Design and Average Radium (226) Concentrations</u>

The Petitioner's Risk Assessment and the Arcadis Response to EPA Comments on January 16, 2020 (Appendix 4a) compile and discuss in more detail the potential uncertainties in the risk assessment and the justification for the RMEs. For example, the design criteria used in the risk assessment were set at RME. The process of selecting the RMEs for this Petition was performed after evaluation of the road construction process and extensive pre-petition dialogue with EPA staff.

For example, TFI's consultant intentionally chose (and EPA staff tentatively accepted) a deterministic approach. A full probabilistic approach is resource intensive, but in this situation use of a reasonable maximum exposure (RME) and an explanation of the risk distribution achieves the same goal as a probabilistic approach (see Appendix 4a: Response to EPA Comments on January 16, 2020). The RME is one point on a probabilistic distribution (see conceptual figure provided below, Figure 3, which uses 90th percentile to illustrate the concept). EPA guidance does not dictate a particular percentile as an RME, e.g., the RME for the duration of living at home is 90th percentile, but some EPA risk assessments utilize lower percentiles depending upon the facts.

ED_005285_00000744-00017

Figure 3: Conceptual Illustration of Probabilistic and Deterministic Frameworks



(This conceptual figure uses a 95th percentile to illustrate a high end exposure. But as noted in EPA guidance the assessor may derive a high-end estimate of exposure by using maximum or near maximum values for one or more sensitive exposure factors, leaving others at their mean value.)[33]

The Response to EPA Comments on January 16, 2020[34] describes in more detail the substantive rationale for the RME selections and the impact of variations in design factors.

For example, the Petitioner's Risk Assessment used a distance of 50 ft between roads and homes.[35] According to the Federal Highway Administration, the "new Interstate road needs a right-of-way width of 150 to 300 feet or more; a generation ago, roadbuilders could get by with 50 or 75 feet."[36] The larger the right of way, the lower the radiation level to residents.

Also, the Petition's Risk Assessment calculated the risk based on a road bed containing 50% PG and 50% soil. A 50:50 mixture of PG and local construction materials:

> "[I]s likely to be an overestimate of the actual mix. The EPA for example in their 1992 BID used a 1:2 mix of PG:sand. This is also the ratio in the Polk and Columbia county roads constructed by FIPR with input on the design and testing of the roads from the University of Miami and the Bureau of Materials & Research, the Florida Department of Transportation. This ratio is less than the ratio of two parts PG to one part soil utilized in EPA's 1992 BID risk assessment."[37]

---

[33] Exposure Factors Handbook, *supra* note 11.

[34] Appendix 2 to this Petition is the same as the Petition's Risk Assessment (Petition's Risk Assessment). Appendix 4a addresses questions EPA raised concerning the original risk assessment (Response to EPA Comments on January 16, 2020).

[35] Petition's Risk Assessment at 3-2.

[37] Petition's Risk Assessment, *supra* note 34, at 2-5 n. 9 and Response to EPA Comments on January 16, 2020, *supra* note 34, see answer to EPA question 5.

ED_005285_00000744-00018

Thus, EPA and other precedent accepts a 50-50 ratio as a RME. If the specific design for a particular road contains less than 50% PG then the risk is lower than the risk from RME.

Similarly, the concentration of radionuclides in concrete paving was assumed to be 2.25% PG, based on PG 15% by weight in cement and cement 15% by weight in concrete which is the same assumption utilized in the EPA 1992 BID risk assessment.[38] As a practical matter, the literature on the use of normal "gypsum" supports an upper limit of 15%.[39] If less than 15% PG is used, the average PG in the cement is less than 2.25% PG in surface pavement and the risk is lower than calculated in the Risk Assessment. Consistent with EPA policy, 50% PG for road base and 2.25% for surface pavement are appropriate RMEs. Also evaluated are the inevitable relatively slight variations in the risk potentially due to slight variations in the implementation of a 1 to 1 ratio of PG to soil in the road bed design standard (e.g., if the ratio 1.2 to 0.8 instead of 1 to 1) and the 2.25% PG in road surface design standard (e.g., if percentage of PG in the road surface is 2.7% instead of 2.25%). These variations in the input into the Risk Assessment do not significantly increase the risk. As noted above, various ratios of PG to soil were studied (from 100% sand to 100% PG) and all mixes had California Bearing Ratio values higher than sand or PG separately. See generally Appendix 4a.

As demonstrated in Appendix 4a, most of the other design features do not increase the level of radioactive emissions from the road. For example, the dose to a local resident adjacent to the road does not increase if the road has eight lanes or two lanes.

The data on the concentration of Radium-226 in the stacks (see summary above and more detailed discussions below in this Petition and in Appendix 5) are all well below the nominal concentration used in the risk assessment, therefore, the actual risk from PG use is likely to be well below the risk calculated in the Petition's Risk Assessment.

---

[38] Petition's Risk Assessment, *supra* note 34, at 2-5.

[39] Since PG cannot be used in road construction in the U.S., the literature on PG is limited. However, the literature on the percentage of gypsum used in cement suggests that 15% is a reasonable number. For example, the "optimum addition of gypsum for Atbara clinker would be in the range of 3% to 5%." Amin Abdelrahman & Mohamad H. Aboud, Determination of Optimum Quantity of Raw Gypsum Addition for Atbara Cement Clinker, Khartoum University, 5, *available at* http://www.jeaconf.org/UploadedFiles/Document/82d8a051-43ad-44fa-ab1d-1ac182000608.pdf.

Similarly, the gypsum content of 5% in the composition of cement is referenced. *Available at* https://www.engr.psu.edu/ce/courses/ce584/concrete/library/construction/curing/composition%20of%20cement.htm.

Further, another article cites the use of 3% to 5% gypsum in cement. Karen L. Scrivener, Vanderley M. John, & Ellis M. Gartner, Eco-efficient cements: Potential economically viable solutions for a low-CO2 cement-based materials industry, Cement and Concrete Research. Vol. 114, 2-26 (Dec. 2018), *available at* https://www.sciencedirect.com/science/article/pii/S0008884618301480?via%3Dihub.

There is a significant reduction in the split tensile strength at 15% phosphogypsum content. Thus the optimum amount of phosphogypsum in concrete is found to be 10%. Kuriakose Reju & P.K. Shaji, Effect Of Calcined Phosphogypsum In Portland Pozzolana Cement Concrete, International Research Journal of Engineering and Technology (IRJET) Vol. 05, Issue: 04, 2008 (Apr. 2018), *available at* https://pdfs.semanticscholar.org/d7cc/03c3de65ca412971fff244b37098d479d4ab.pdf.

All of the risk values in Table 1, above, are based on the RME assumptions and the assumption that the average radium (226) concentration in this PG is 27 pCi/g. The use of a radium (226) concentration of 27 pCi/g was chosen so that the submission contained a calculated risk which corresponds to a "nominal" concentration of radium (226).[40] Since the relationship of radium (226) concentration in PG to risk is proportional, the risk from using PG containing any other concentration of radium (226) in road construction can be calculated from the nominal concentration. Thus, a concentration of radium (226) in PG of 35 pCi/g (the radium (226) concentration proposed in the Second Revised Petition as the radium (226) concentration limit on PG used in road construction) can easily be calculated to be 0.65 in 10,000 (well below the risk management level used in the PG use guidance of 3 in 10,000). Conversely, the risk of 3 in 10,000 (EPA's safe risk level) corresponds to a radium (226) concentration in the order of 148 pCi/g (see this section and Sections III(G), V, V(D)(3,4), below). The discussion of the rationale for selecting a radium (226) concentration limit of 35 pCi/g is explained below

The use of 27 pCi/g is a reasonable value for the "nominal" radium (226) concentration given historic sampling of U.S. PG stacks and the average radium (226) concentrations utilized in the 1992 EPA BID risk assessment. However, TFI members sampled nine stacks located in four states in 2019.[41] The average radium (226) concentration of all 90 samples was 18.6 pCi/g with individual samples ranging from 6.3 pCi/g to 27.9 pCi/g.[42] The average concentration of radium (226) per PG stack ranged from 7.44 to 24.7 pCi/g (which is relevant because the PG for road construction use is likely to be from an individual stack). Within each stack sampled, the ratio of the highest to lowest measured concentration ranged from 1.2 to 3.7 pCi/g. These recent data found average stack radium (226) concentrations are well below the nominal concentration of 27 pCi/g used in the Petition's Risk Assessment, the 35 pCi/g concentration limit proposed in the Petition as the limit in the PG used in road construction, and significantly below the 148 pC/g corresponding to the 3 in 10,000 safe risk level.

If the average concentration of radium (226) per PG stack measured by TFI members (i.e., 4.77 to 24.7 pCi/g) is utilized in the risk assessment, the RME construction worker's risk from the PG used in road construction work ranges from about 0.09 in 10,000 to 0.5 in 10,000. Similarly, the risk to nearby residents directly adjacent to the road (the RME individual) is approximately 0.01 in 10,000 (1.4 in one million) to 0.7 in 10,000.

Given the range of individual concentrations in the historic and recent sampling of PG stacks and the variation within the stacks between the highest and lowest radium (226) concentration, it is exceedingly unlikely that the average concentration of radium (226) in any stack would be close to 148 pC/g. Thus, variations in radium (226) will not significantly increase the risk and, in any case, the PG limit is 35 pCi/g, well below the 3 in 10,000 safe risk level. Thus, EPA could approve use of PG from stacks without any sampling.

---

[40] An average of 35 pCi/g also represents the highest average level identified in prior testing by EPA. To account for some potential variability (~30 percent) that has been observed in past testing, the relief sought in this petition seeks approval to use PG containing radioactivity levels of up to an average of 35 pCi/g in road construction materials.

[41] TFI, Supplement to the October 11, 2019 TFI Phosphogypsum Reuse Petition: 2019 Radium-226 Results for U.S. Phosphogympsum Stacks,1 (December 5, 2019) (TFI 2019 Sampling). Further discussion of this new data is provided below.

[42] *Id.* at 1.

The proposal in the 2019 Petition and this Second Revised Petition proposes annual sampling to provide continuing documentation that each shipment does not contain PG with an average radium (226) concentration above 35 pCi/g. The reasons for this suggested limit are as follows. First, a radium (226) concentration of 35 pCi/g is well below the radium (226) concentration of 148 pCi/g that corresponds to the 3 in 10,000 risk level (EPA's "safe" level). Thus, a maxium average concentration of radium (226) of 35 pCi/g is "safe." Second, TFI recognizes that EPA historically has utilized this regulatory approach so the likelihood of approval of the Revised Petition will be enhanced if the approval uses a maximum radium (226) concentration. Third, the requested limit of an average radium (226) of 35 pCi/g represents the highest average level identified in prior testing by EPA. Thus, this approach will make implementation more efficient. Fourth, an average radium (226) concentration of 35 pCi/g for PG used in road construction materials will account for some potential variability (~30 percent) that has been observed in past testing and during implementation of road construction. Finally, as more data is gathered over time during the implementation of this new use, TFI reserves to right to request EPA modify its approval to include a more efficient implementation approach.

The Response to the EPA Comments on January 16, 2020 performed a series of additional evaluations of the impact from the uncertainty in each of the exposure scenarios and found no significant increase in total risk, even when using the assumptions postulated in the EPA comments. In any case, the postulated assumptions are all less conservative than the RME scenario and did not warrant a change in the risks in the Petition's Risk Assessment.

Thus, consistent with the regulations governing EPA's approval of PG uses, the use of PG in road construction is safe and at least as protective as placement of phosphogypsum in a stack.

Table 2, below provides a summary of comments on risk distributions by exposure pathway. The table explains the limited applicability of the RME scenario and the potential for lower exposures and doses to occur for a broader population (taken from the Response to EPA Comments on January 16, 2020).

TABLE 2: SUMMARY OF RISK DISTRIBUTION FROM USE OF PG IN ROAD CONSTRUCTION

Exposure Scenarios	RME (small number of people)	Potential Lower Exposures and Risk Distribution
Road Construction Worker	Risk: 0.5 in 10,000 Few if any workers would fit the RME assumption of 100% of workdays on the uncovered road base. The RME worker is exposed to less than 7% of background levels (for all members of the public).	Much less than 0.5 in 10,000 Most workers are expected to spend less than 100% of the workday on the uncovered road base. Dose and risk reduce linearly with reduced exposure time. Time on a covered road base was shown in the Risk Assessment to be a factor of 5 lower. The dose would range down to essentially zero for management and supervision who would spend very limited time on the road and out of vehicles. The number of workers in a road crew is estimated to be as small as 6 – 8 workers, which limits the risk distribution to a small group.
Road User	Risk: 0.1 in 10,000	Well below 0.1 in 10,000

ED_005285_00000744-00021

TABLE 2: SUMMARY OF RISK DISTRIBUTION FROM USE OF PG IN ROAD CONSTRUCTION		
	This RME is assumed to be a heavy user of the road spending 2 hours daily on the road. This scenario is unlikely to occur until far into the future if PG roads become widely available. Until then it is unlikely a commuter would be able to spend this amount of time on a PG road. In the extreme case, the RME road user is exposed to less than 0.3% of background.	Most road users will be on the road for much less than two hours per day. Dose and risk reduce linearly with reduced exposure time. Initially when PG use in roads is newly implemented the availability of PG roads will be low reducing the opportunity to have substantive usage time. As the total amount of PG roads increase the risk distribution would increase with additional road users and cumulative usage time. The overall risk to an individual however, is not expected to exceed the RME estimates. Most road users would still have limited time on PG roads and this results in a proportionally limited dose and risk. The overall number of road users is difficult to specify as it depends on several factors including the road type and location relative to populated areas. However, the dose to road users would remain a small fraction of that from unavoidable background radiation.
Truck Driver	Risk: 0.5 in 10,000 The Truck Driver RME is limited to workers who participate in PG road construction projects. The assumptions for this scenario are set to estimate the upper end of likely dose and risk for this work. The RME Truck Driver is exposed to less than 6% of background levels.	A truck driver that has less than an RME exposure has lower risk than 0.5 in 10,000. There are a limited number of truck drivers involved in a road construction project. In addition, truck drivers will support numerous construction projects during the course of a year and many not involving use of PG. This limits the risk distribution for this exposure pathway to a relatively small number of people. In many cases, Truck Drivers will not work on PG road construction as much as assumed for the RME, resulting in a lower dose and risk.
Nearby Resident	Risk: 0.08 in 10,000 The Nearby Resident RME is based on extreme assumptions that are unlikely to apply to all residents of a PG road. The assumptions include close exposure to the road and long durations of residency throughout the exposure period. Based on these assumptions the Nearby Resident RME is exposed to 0.2% of background levels.	Most residents near a PG road would be exposed to much lower doses and risk, well below 0.08 in 10,000. Radiation levels from a PG road decrease rapidly with distance from the road and become indistinguishable from background at 50' to 100'. As a result, most residents immediately beside a PG road would be exposed to much less than the RME risk level, and residents beyond the immediately adjacent properties would experience essentially zero incremental risk. The overall risk distribution would depend on the overall length of the PG road and population density along the road but is limited to only those locations immediately beside the PG road.
Utility Worker	Risk: 0.004 in 10,000 The Utility Worker RME scenario represents an extreme case where a worker needs to disrupt the road for	Most Utility Workers would be exposed to risk much less than 0.004 in 10,000. Most utility repair requirements would involve exposure scenarios below those assumed for the RME conditions,

ED_005285_00000744-00022

TABLE 2: SUMMARY OF RISK DISTRIBUTION FROM USE OF PG IN ROAD CONSTRUCTION		
	road or utility maintenance. The assumptions use worst case conditions to estimate the risks and are limited to workers in a trench in a PG road and meeting the other exposure assumptions. The RME Utility Worker is exposed to approximately 0.3% of background levels.	due to smaller trenches and exposure areas, or shorter durations. The number of individuals entering a trench in a PG road is also limited based on the uniqueness of the work and the limited space. As a result, the risk distribution for the Utility Worker is limited to a small number of individuals.
Reclaimer Extreme Scenario	Reclaimer is an extreme scenario well beyond an RME assumption and therefore, is not appropriate to determine whether the use of PG is safe. This example for ultimate disposal was selected due to the use by EPA in 1992. Risk: 0.4 in 10,000 The Reclaimer would be exposed to approximately 1% of background levels. (total exposure of 78 mrem compared to a Background of 8,060 mrem over 26 years)	The Reclaimer scenario represents an extreme situation that is unlikely to even occur as described (Appendix 4b: Responses to Second Set of USEPA Questions - Reclaimer). As a result, the risk distribution is effectively zero. More realistic situations for the ultimate disposal of the road include continued use of the road as a road, or reuse of the PG road base for a new road, if the road was to be relocated or realigned. In the extreme case where a road is abandoned and then the land is reused for other purposes, the land preparation activities will realistically result in blending and mixing of the road base to levels that are indistinguishable from background levels. Overall, the risk distribution would be effectively zero.

In summary, the risk distribution from road construction is negligible, beyond the individuals who are on or immediately beside the road, as assessed in the Risk Assessment document. Thus, consistent with the regulations governing EPA's approval of beneficial uses, the use of PG in road construction is safe and at least as protective as placement of phosphogypsum in a stack. [43]

II. PETITION REQUEST AND LEGAL REVIEW PROCESS

A. Specific Relief Sought

This Petition requests the following:

[43] EPA's "assessment of the maximum individual lifetime risk of fatal cancer from radon emissions from stacks" was "less than three in ten thousand (3 x 10-4) to the maximally exposed individual." EPA, Applying to EPA for Approval of Other Uses of Phosphogypsum: Preparing and Submitting a Complete Petition Under 40 CFR 61.206: A Workbook, 5 (2005), *available at* https://www.epa.gov/sites/production/files/2015-05/documents/wrkbk_sub-r_appl_1105.pdf (EPA PG Workbook).

Therefore, "the risk assessment must demonstrate that the proposed other use will not cause a threat to the public or environment greater than if the phosphogypsum were left in the stack. This means that the risk assessment must show that the chance of developing a fatal cancer in people who are exposed to phosphogypsum as a result of the use for which you are applying must not be more than three in ten thousand (3×10^{-4})." *Id.* at 13.

ED_005285_00000744-00023

A determination by EPA, pursuant to 40 CFR § 61.206, that PG containing up to an average of 35 pCi/g may be used in road base, paving, and various combinations of road base and paving in Government Roadway Projects that meet the commitments of this petition and are:

1. Authorized by federal, state and local Departments of Transportation (DOT) or Public Works (PW), and

2. Conducted as part of a government road project using appropriate, generally accepted road construction standards and specifications such as ASTM, FHWA, federal or state DOT standards and specifications, or standards developed or approved in consultation with the appropriate regulatory DOT or PW authorities.[44]

B. Legal Review Process

1. Components of Petition

40 CFR § 61.206(b) provides the Petition must be in writing and should address the following topics:

- The name and address of the person(s) making the request.
- A description of the proposed use, including any handling and processing that the phosphogypsum will undergo.
- The location of each facility, including suite and/or building number, street, city, county, state, and zip code, where any use, handling, or processing of the phosphogypsum will take place.
- The mailing address of each facility where any use, handling, or processing of the phosphogypsum will take place, if different from paragraph (b) (3) of this section.
- The quantity of phosphogypsum to be used by each facility.
- The average concentration of radium-226 in the phosphogypsum to be used.
- A description of any measures which will be taken to prevent the uncontrolled release of phosphogypsum into the environment.
- An estimate of the maximum individual risk, risk distribution, and incidence associated with the proposed use, including the ultimate disposition of the phosphogypsum or any product in which the phosphogypsum is incorporated.

[44] There are 50 states and each has its highway design guidance documents. Federal and state transportation departments generally cite the Green Book, *supra* note 20. Attachment B contains representative examples of road way specifications (including alternative materials that may be used in road construction from Florida, Louisiana, Idaho, and North Carolina and the Green Book).

ED_005285_00000744-00024

- A description of the intended disposition of any unused phosphogypsum.

- The Petition must be "signed and dated by a corporate officer or public official in charge of the facility."

2. EPA's Determination and Risk Management Decision

The decision to approve a new use for PG must be made by EPA's Assistant Administrator for the Office of Air and Radiation (OAR). As a matter of policy, the decision involves weighing results of a risk assessment, technical analyses, and other factors.[45]

Section IV summarizes the Risk Analysis and metals screening evaluation that have been completed and demonstrate the safety of PG use in road construction. Key exposure and risk calculations and application of EPA's risk management criteria are described.

Section V provides TFI's justification for approval of this Petition and explains these factors as TFI submits they should apply to EPA's risk management decision. In conclusion, the road construction scenarios were evaluated for numerous risks (e.g., a broad scope of RME radiological exposures and non-radiological constituents present in PG). The analyses clearly demonstrate that:

- Use of PG in road construction presents no greater risk than stacking of the material; and

- PG can be safely used in road construction. In scientific terms, the use presents a risk of < 3 x 10,000, the level deemed by EPA to be safe (see discussion below).

3. Information and Certifications Required to Implement EPA Determination

Once the Assistant Administrator decides to approve use of PG in road construction under 40 C.F.R. 61.206(c), each of the reporting and records requirements at §§ 61.206(d) and 61.207-209 must be met. The only limitation on these requirements is that certain record-keeping obligations at § 61.209 may be waived. These reporting requirements include reporting the annual average radium-226 concentration at the removal location, and certification documenting purchaser, quantity and use information, along with a requirement that records must be retained for five years. These requirements ensure that EPA records contain information under §61.206(b) and in any event ensure that PG use and distribution is closely managed even where it is removed from a stack for an approved use.

[45] Basic concepts and definitions to aid the reader's understanding of the Petition can be found in Key Definitions which is a preamble to this Petition.

ED_005285_00000744-00025

III. REGULATORY HISTORY AND CHANGING CONDITIONS

A. Regulatory History

1. The Original 1989 NESHAP Rule

Prior to 1989, PG in the United States was used for beneficial purposes, such as constructing roadways and agricultural soil amendments. The 1989 NESHAP rule required that all PG must be placed in engineered above ground impoundments (commonly referred to as "gypstacks") or in phosphate mines where it can be used as backfill. 40 CFR § 61.202. EPA's 1989 regulatory analysis was based on an estimate of 66 stacks located in 12 states with two-thirds located in Florida, Texas, Illinois, and Louisiana.[46]

2. Post-1989 Regulatory Developments

After the issuance of the 1989 NESHAP rule, TFI petitioned for reconsideration. EPA agreed to reconsider that portion of subpart R that required that all PG be disposed in stacks or mines.[47] On June 3, 1992, EPA published a final rule approving PG use as an agricultural soil amendment and for indoor research and creating a framework for approving additional alternative uses.[48] In particular, EPA approved the use of PG as an agricultural soil amendment as long as the average concentration of radium-226 in the PG does not exceed 10 pCi/g (based on a maximum individual risk of 3 in 10,000 due to the use) and use of PG for research in amounts not to exceed 7,000 pounds. 40 CFR § 61.204-205.[49]

The amended regulations also allowed OAR to approve, on a case-by-case basis, a new use if it is as protective of public health, in both the short and long term, as disposal in a stack or a mine. 40 CFR § 61.206(a)-(c).[50] In 1992, EPA rejected the use of PG in road construction based on an analysis that assumed a roadway constructed with PG might be abandoned in the future, with a home constructed directly on top of the abandoned roadway with no site preparation (i.e., mixing). This hypothetical scenario included several extreme assumptions that resulted in unrealistic levels of exposure (i.e., it was not a RME).[51] For example, the 1992 EPA BID assumed a 70 year period for the duration of residential exposure for the hypothetical reclaimer exposure scenario even though the 1992 EPA BID used 25 years as the duration of a resident's exposure for the nearby resident. EPA's current RME for the duration of residential exposure is 26 years (a 90th percentile of exposure), precisely because "EPA has been criticized for too often

[51] *Id.* at 23,312.

assuming that future use will be residential" and other unrealistic assumptions.[52] Also see Appendix 4b: Responses to Second Set of USEPA Questions – Reclaimer.

3. Prior Petitions

On December 22, 2004, EPA "conditionally" approved the Petition of the Florida Institute of Phosphate Research (FIPR) to use PG as cover material in a demonstration landfill test cell project (discussions with EPA on this project were initiated in 2002 and the petition submitted December 9, 2003).[53] PG, however, was never used as cover material in a landfill test cell. As TFI understands it, by the time the petition was approved, conditions had changed and the landfill owner withdrew its request.

In 2010, Louisiana State University prepared a proposal to allow the use of PG testing to determine if PG could be used to make coastal zone protection devices.[54] TFI's understanding is that this effort proposal did not advance to the submittal of a petition.

These examples illustrate the unwieldiness of EPA's current approach to approvals for PG use. This has resulted in continued stacking, which has been subject to criticism as an unsustainable practice.

B. Factors Influencing Future Uses of PG

A number of factors influence the future uses of PG:

1. Current requirements to obtain regulatory approval prior to each individual new use slow the process of implementing beneficial, safe new uses. In many other countries, PG use is encouraged over storage and there are little or no regulatory restrictions on the use of PG up to an average radium (226) content of 27 pCi/g.[55]

2. The size, costs and complexity of gypstacks have increased (see, Appendix 6 Economic Analysis of Regulatory Costs Savings) well beyond original expectations. When the stacking solution was developed, two key factors were not fully recognized: (1) growth in the industry would result in a significant increase in the volume of PG material that would require storage capacity in stacks, and (2) the beneficial use for which PG could safely be employed. Today, active stacks are concentrated in Florida, Idaho, Louisiana, and North Carolina and contain at least 1.7 billion tons of stored PG. EPA's final rule did not anticipate the significant increase in production that would occur, creating a need for new storage capacity to handle the

[55] IFA Sustainable PG Management Report, *supra* note 12.

PG production rate of 46 million tons per year. As a result, EPA's 1989 final rule and its underlying analysis did not consider the full extent of present (and future) environmental impact and cost of long-term stack storage on a scale compatible with modern fertilizer production facilities.

3. Historically, EPA considered the radium-226 concentrations in individual phosphogypsum samples as ranging from 1.4 to 46 pCi/g.[56] At EPA's request, TFI members performed radiation sampling on gypstacks across the U.S. in 2019 to provide updated information (Appendix 5). Multiple stacks owned and operated by three companies were sampled (ten samples per stack were taken). The 2019 sampling found:[57]

- Radium (226) concentrations of individual PG samples ranged 6.3 to 27.9 pCi/g.
- The average radium (226) concentrations of all 90 PG samples from all stacks is 18.6 pCi/g.
- The average radium (226) concentrations per stack ranged from 7.46 pCi/g to 24.7 pCi/g. An EPA 1988 report states the mean concentrtions of radium (226) from Florida stacks ranged from 25 to 34 pCi/g.
- The average average radium (226) concentrations from PG samples taken from six Central Florida stacks is 19.6 pCi/g and for the Western US stacks is 15.8 pCi/g.
- Limited data reported in the literature on the concentrations of radium (226) in PG outside of the U.S. indicate that concentrations range from 6.7 pCi/g to 38.4 pCi/g, well below 148 pCi/g that corresponds to a risk of 3 in 10,000 (N.B.: Some data are average concentrations and others report as few as one sample).

The 2019 data demonstrate that the average radioactivity level for each stack is significantly lower than the 35 pCi/g radium (226) concentration limit requested in the Petition and less than 148 pCi/g which corresponds to EPA's safe risk level of 3 in 10,000. All of 2019 stack averages are below 27 pCi/g (the nominal concentration used in the risk assessment), thus, the risk for these stacks is below 0.5 in 10,000.[58]

---

[56] EPA 1992 BID, *supra* note 15.

[57] TFI 2019 Sampling, *supra* note 41, at 1-5.

[58] The Risk Assessment found that the nominal level of radium (226) assumed for calculation purposes to be contained in PG (27 pCi/g) corresponds to a maximum risk of 0.5 in 10,000. Thus, the EPA PG risk management limit of 3 in 10,000 corresponds to a level of 148 pCi/g in PG (using the non-rounded risk for the construction worker). Therefore, PG may be safely used as road construction material.

4. The scientific community has developed an updated understanding of relative risks associated with PG.[59] This Petition has been prepared to enable EPA's regulatory decision to be based on the current, best scientific understanding of radiation protection and management related to PG use. The International Atomic Energy Agency (IAEA), an international organization which the U.S. helped establish to provide a scientific source of recommendations on radiation issues, has determined that radionuclide activity concentrations in PG material are less than 1 Bq per gram (Bq/g) (which corresponds to 27 pCi/g) "implying that it is not necessary to regulate."[60] Section IV below summarizes this updated understanding. U.S. and international research, as well as data from uses in developed nations, are now available to support various PG uses and demonstrate that PG use is at least as protective of public health as storage in stacks. More than a dozen beneficial uses have been analyzed worldwide, resulting in significant, successful PG use applications in at least 21 countries.[61]

Further, U.S. risk assessment approaches have changed based on experience and evolving environmental management policies since the 1980s, along with increased awareness of product lifecycles and sustainability. These changed conditions enable a more thorough and appropriate evaluation of PG use in road construction, and a demonstration that this use is protective of human health and the environment.

5. EPA policies encourage use and recovery of high-volume, low-risk waste. EPA's 1989[62] and 1992[63] risk management decisions concerning PG uses acknowledge, but do not provide, an effective mechanism to implement PG use decisions that are consistent with the Agency's overarching policy of supporting recycling. Since 1992, EPA has increased its emphasis on understanding product lifecycles and has adopted sustainability policies and encouraged sustainable practices.

6. The economics of gypstacks have changed. The cost to stack PG and manage gypstacks is increasing. These rising costs are a concern to U.S. phosphate fertilizer producers that must remain competitive in a global marketplace. Fertilizer companies outside the U.S. may use or sell for use their PG material safely utilizing the IAEA standards and avoid costs attendant to stacking. This puts U.S. companies at a significant economic disadvantage. The international community has actively moved in the direction of safe PG use and recycling, creating an increasing competitive

[63] 1992 Rule, *supra* note 48, at 23,306.

disadvantage for U.S. industry, particularly when one considers the costs associated with gypstack maintenance, closure, and long term care.

7. Perceptions of gypstacks have changed. EPA's final rule did not anticipate advese public sentiment from local stakeholders regarding the long-term presence of gypstacks, including aesthetic concerns. Some local governments and communities have expressed a preference for use of PG in a manner that encourages redevelopment of land currently utilized by and around gypstacks.[64] Such use increases economic development by generating jobs associated with the transportation and use of PG, and frees up land for other uses (Appendix 6).

8. TFI's proposal represents a significant regulatory burden reduction that will create new commercial markets, industries and jobs. This is in the context of the dramatic increase in PG use worldwide since 2008, from a baseline of close to zero to 35-40 million tons consumed worldwide by 2015.[65] To make comparable advancements, the U.S. phosphate industry, EPA approval of TFI's Petition would support the industry's sustainable development goals by expanding the list of PG beneficial uses and ameliorate substantial, avoidable regulatory burdens and costs imposed by the NESHAP Subpart R regulations.

IV. SUMMARY OF THE EVALUATIONS CONDUCTED FOR THE PETITION

A. Overview

EPA's document, titled "Applying to EPA for Approval of Other Uses of Phosphogypsum: Preparing and Submitting a Complete Petition under 40 CFR 61.206, A Workbook" (EPA PG Workbook) provides a guide for the Petition.[66] The key requirement expressed in this guidance (and the NESHAP) is that in responding to any proposed petition, EPA must decide whether the radiological risk associated with the alternative use poses no greater risk than placement in stacks.[67]

The decision concerning whether the radionuclide risk associated with PG in alternative uses is acceptable depends upon many risk analysis elements, including:

- The specific exposure scenarios that are determined to be appropriate. This Petition seeks approval of the use of PG in road construction based on a risk analysis for a series of specific exposure scenarios;

---

[64] *See e.g., EPA holds meeting about Mississippi Phosphate Site*, St. Louis Post-Dispatch, Jan. 11, 2018, *available at* https://www.stltoday.com/news/world/epa-holds-meeting-about-mississippi-phosphate-site/html_0a41e1fa-96ef-54bb-a825-8fcaeb4b4463.html (comment of Pasagoula Mayor, Dane Maxwell, at an EPA public meeting regarding the Mississippi Phosphate site cleanup: "We want it clear and ready for development as soon as possible").

[67] *Id.* at 12.

- The RME exposure assumptions or parameters that are selected to estimate a high end radiation dose estimate during the alternative use of PG, i.e., an assumption likely to overestimate exposure. This Petition developed RME exposure assumptions for each exposure scenario and receptor based on high end construction design features that may affect the radiation dose and calculated a high end RME dose;

- The radiation dose to risk conversion factor used, see Attachment A;

- The cancer risk estimate based on RME exposure assumptions and the radiation dose to risk conversion factor of 5 in 10 million mrem;

- EPA's cancer risk limit for new PG uses of 3 in 10,000 during the use;

- A comparison of the estimated cancer risk to EPA's risk limit for new PG uses; and

- EPA's Risk Management Decision considering economic and other risk management factors.

EPA did not assess chemical risk from residual metals in its 1989 risk assessment or its 1992 risk assessment (which approved an agricultural use and denied approval to use PG for road construction).[68] In the 1992 EPA BID risk assessment, EPA stated that PG "contains some trace metals in concentrations which the EPA believes may pose a potential hazard to human health and the environment," particularly arsenic, lead, cadmium, chromium, fluoride, zinc, antimony, and copper.[69] The "trace metals also may be leached… and migrate to nearby surface and groundwater resources."[70] However, EPA explicitly decided in the 1992 EPA BID that these metals "will not be addressed in the risk assessment."[71] Thus, neither the 1992 EPA BID risk assessment for the approved use of PG as an agricultural amendment nor the 1992 risk assessment for use of PG in road construction (which was not approved) included a risk assessment or a screening level assessment for metals in PG.

For this Petition, however, EPA requested that TFI perform a risk screening level evaluation for the naturally-occurring radioactivity and metals. Although there is a question concerning whether EPA's NESHAP program has the legal authority to require an risk assessment of the impact of metals in PG used for road construction, TFI performed a high end exposure (i.e., RME or higher exposure) for the human health risk screening. That screening assessment concluded that the metals levels in PG are not expected to pose an unacceptable level of health risks to construction workers or cause an unacceptable impact in groundwater using PG in roadway construction. Thus, no further risk evaluation is warranted to assess risks from metals in PG used for road construction. Furthermore, proper construction practices employ BMPs such

as wetting surfaces to reduce dust formation, and these measures serve to further lower exposure. Studies and the nature of the petitioned PG use in road construction material compacted or encapsulated below pavement and above the water line indicate that leaching to groundwater (or surface water) is unlikely (ie., it is not a complete exposure pathway that warrants a more detailed risk assessment of the metals). The relevant Department of Transportation has responsibility to ensure that construction, using any construction materials (including PG), is to conduct construction activities in a manner that is protective of human health and the environment.

B. Exposure Scenarios

1. Overview

PG use was considered for road construction. This led to the development of the following RME exposure scenarios evaluated in the risk assessment:

- Road Construction Worker who builds roads exclusively with PG material for five years;
- Road User who routinely commutes on the constructed roadway by vehicle, motorcycle or bicycle for 26 years (motorist/bicyclist was deemed most conservative);
- Nearby Resident who lives in a home located 50 feet or more from a PG roadway for 26 years. To illustrate the amount of exposure reduction with distance, exposure to a resident who resides 20 feet from the PG roadway for 26 years was also calculated;
- Truck Driver who delivers PG for road base material to a construction site for five years; and
- Utility Worker who excavates across a PG roadway during utility maintenance projects and is exposed in a trench for 160 hours in a year.

These exposure scenarios were selected based on a review of prior regulatory submissions as well as discussions with EPA personnel, and the best professional judgment of the scientists assisting in the preparation of the Petition.[72] This analysis includes receptors not utilized by EPA in its 1992 BID risk assessment but added at EPA's request during the working sessions to fully evaluate public health.

This Petition also includes, at EPA's request, a hypothetical scenario which assumes a home is built upon an abandoned road constructed with PG (the so called Reclaimer scenario), which results in an extreme exposure (Extreme Reclaimer), i.e., the exposure is much higher than a RME exposure scenario. The probability of this scenario is very remote and implausible in that this construction scenario would likely never occur under existing road construction practices

[72] Arcadis (a firm specializing in design and consultancy for natural and built assets) and Exponent (an engineering and scientific consulting firm).

ED_005285_00000744-00032

and contraints on future land use for public infrastructure and therefore, the assumed scenario is not reasonably likely (Appendix 4b: Responses to Second Set of USEPA Questions - Reclaimer). Although this scenario also meets the EPA risk management limit of 3 in 10,000, it is not a reasonably likely scenario and therefore should not represent a condition of approval.

The design and construction of roadways is governed by policies and constraints on future land use associated with public infrastructure. The Reclaimer scenario of building a house on top of an abandoned roadway is not consistent with typical land re-use and sustainability policies, is limited by the legal constraints on abandoning public roads, is extremely rare (research has found few, if any, examples), and ignores the economic factors favoring using existing roads even if the land is being redeveloped. Therefore it is not a reasonably anticipated land use.

Nevertheless, EPA requested this evaluation to provide historical context for the 1992 EPA BID and confirm that this scenario is not a logical concern. This is discussed in further detail in Section IV (D)(9), below.

2. Reasonable Maximum Exposure (RME)

In order for there to be a risk, there must be exposure. EPA uses an RME metric to assess exposure risk. The "intent of the RME is to estimate a conservative exposure case (i.e., well above the average case) that is still within the range of possible exposures."[73] Each exposure factor used to estimate the RME should be selected "so that the resulting estimate of exposure is consistent with the higher end of the range of plausible exposures" (citing EPA's 1991 guidance).[74]

A National Academy of Science (NAS) Committee reviewing EPA's regulation of technologically enhanced naturally occurring radioactive material (TENORM) recommended that EPA "should use exposure and dose risk assessments that are 'reasonably realistic'" in developing standards for exposure to the various types of low level naturally occurring radiation.[75] "The Committee defined 'reasonably realistic' as 'not....intended to greatly overestimate or underestimate actual effects for the exposure situation of concern,'" and EPA agreed with the Committee's recommendations.[76]

The exposure calculations in the Petition use currently accepted radiation modeling methods such as RESRAD and MicroShield. State regulators, citing to EPA guidance, note that "if high-end values are chosen for every exposure factor, then the resulting exposure estimate may no longer be consistent with the RME and may exceed the realm of possibility altogether."[77]

[76] *Id.*

[77] ITRC, Decision Making at Contaminated Sites, *supra* note 10, at 6.1.1.

The use of reasonable exposure assumptions is supported by the courts, which have long held that exposure assumptions "must bear some rational relationship" to actual conditions, and disallowed unduly conservative approaches. For example, a court rejected EPA's use of an extreme assumption - that a child eats sludge applied to roadside cemeteries every day for a five year period.[78]

Scenario-specific exposure assumptions were selected for this analysis in accordance with EPA guidance and methodology (see Table 3 below). These exposure assumptions are contained in appendices and accompanied by detailed scientific support, citations to guidance, discussion of best professional judgment and prior precedent used to make the selections. A summary of key exposure assumptions is provided in Table 3 below.

Table 3: Summary of Key Exposure Assumptions

Person	Description	Years	Model	Rationale
RME Scenarios				
Road Worker	Builds roads exclusively with PG material	5	RESRAD	The worker who uses PG to build a road is closest to the PG mixtures in road base and/or paving. Used Florida Department of Transportation construction project data and EPA guidance. Other road construction workers have lower exposure and therefore less risk.
Truck Driver	Delivers PG to the construction site to be used in road base and/or paving materials	5	MicroShield	A truck driver hauls PG to the road construction site for 5 years (the truck body provides some shielding).
Nearby Resident	Resident lives in a home located 50 feet or more from a road	26	MicroShield	EPA guidance on exposure values. To illustrate the amount of exposure reduction with distance, exposure to a resident who resides 20 feet from the PG roadway for 26 years was also calculated.
Road User	Resident drives on the road in a vehicle, or on a motorcycle or bicycle (the motorist/bicyclist is evaluated as the most conservative)	26	RESRAD	EPA guidance on exposure values.
Utility Worker	Worker in trench dug across a PG roadway (e.g., utility work)	160 days	MicroShield	Best professional judgment, based, in part, on limited time trenching occurs (since, among

[78] *Leather Indus. of America v. EPA*, 40 F.3d 392, 405 (D.C. Cir. 1994).

				other reasons, it obstructs traffic).

At EPA's request, the Petitioner provided a "reclaimer scenario" (an assessment of the extreme hypothetical exposure if the road is abandoned and a house is constructed on the abandoned roadbed (see Table 4)).

Table 4: Reclaimer Scenario Exposure Assumption (see the Petition's Risk Assessment and Appendix 4b: Responses to Second Set of USEPA Questions – Reclaimer)

Hypothetical Extreme Exposure Reclaimer Use Scenario				
Reclaimer Resident	Home constructed on an abandoned road	26	RESRAD (for gamma) Spreadsheet for radon	The abandonment of a road and construction of residential housing at the location is an extremely unlikely event included to evaluate the lifecycle and ultimate disposition of a PG road and is not a RME exposure. See discussion at Section IV(D)(9), below.

The RME is used to calculate the dose (i.e., the amount of radiation that the individual in the exposure scenario receives over a particular unit of time). In our situation, the annual and total doses depend on the length of time exposure occurs for that exposure scenario. Different exposure scenarios have different lengths of exposure. Risk is assumed to increase in direct proportion to the RME dose (i.e., if the RME dose increases by a factor of two, the risk increases by a factor of two).

The risk is then compared to the EPA risk management levels. EPA has long utilized (and courts have long upheld) the principle that a 1 in 10,000 risk level is "safe," although "[t]he upper boundary of the risk range [i.e., the 1 in 10,000 risk level] is not a discrete line." [79] As a unanimous *en banc* ruling of the Court of Appeals for the District of Columbia Circuit candidly noted, the basis for claiming harm from exposure to chemicals at extremely low environmental levels is more a function of "the rules of arithmetic rather than because of any knowledge" and there was "no particular reason to think that the actual line of the incidence of harm is represented" by the assumption selected by EPA.[80]

This acknowledgment is also apt for the risks from radionuclides. EPA's guidance for new uses of PG states unequivocally that for new PG uses to be approved, a petitioner must demonstrate that the cancer risk to those exposed to phosphogypsum as a result of proposed use "must not be

[79] EPA, Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions, OSWER DIRECTIVE 9355.0-30, 2 (Apr. 22, 1991), *available at* https://www.epa.gov/sites/production/files/2015-11/documents/baseline.pdf.

[80] *Natural Resources Defense Council, Inc. v. U.S. EPA*, 824 F.2d 1146, 1165 (D.C. Cir. 1987).

more than three in ten thousand" (i.e., 3 x10^{-4} or 3 in 10,000).[81] In the radionuclides NESHAP, EPA primarily, but not exclusively, evaluated the maximum individual risk (MIR) (which is the added chance of a cancer) and compared it to the NESHAP risk management level of 3 in 10,000.[82]

The use of the 3 in 10,000 "risk threshold is consistent with the determination of a 'safe' level first announced in the NESHAP for certain benzene source categories (54 FR 38044, September 13, 1989)."[83] As noted above, in the 1989 radionuclide rulemaking, EPA determined that six radionuclide source industries presented a cancer risk higher than 1 in 10,000 but that nonetheless was "essentially equivalent" to EPA's safe risk level "in light of the numerous uncertainties."[84] Similarly, EPA reaffirmed in 1992 that a 3 in 10,000 risk level was protective of human health and consistent with EPA's long-standing risk management goals.[85] In particular, EPA "determined" that the 3 in 10,000 risk level provided "an ample margin of safety, considering the cost, scientific uncertainty, and technological feasibility of control technologies needed to further reduce the radon emissions from [the PG] stacks."[86]

In summary, EPA explicitly has determined that the 3 in 10,000 cancer risk for radionuclides (including PG) is safe, consistent with overall EPA risk management policy. EPA has concluded that the "proposed other use will not cause a threat to the public or environment greater than if the phosphogypsum were stored in the stack," if the risk is not "more than three in ten thousand [3 in 10,000]."[87]

The relationship between exposure dose and risk is further elaborated on in Appendices 1 and 2.

C. International Commission of Radiological Protection (ICRP) Dose to Risk Relationship

The risk assessment selected in this Petition is the ICRP dose to risk conversion factor. The ICRP sets out the basis for evaluating health effects from radiological exposure along with recommendations for using specific values for regulatory purposes. While there are broad uncertainty bounds at low-dose exposures, the assumption of a linear relationship between exposure and risk is maintained regardless of the possibility of a threshold below which there is

[82] 1989 Rule, *supra* note 3, at 51,654, 51,659, 51,660. In this context, the risk distribution (i.e. the range of risks to which the population is exposed) decreases as distance to the road increases, for PG use in road construction. Relatively quickly the dose falls below the dose that corresponds to background. The exposure to the residents is below the 3 in 10,000 safe level.

[83] EPA PG Workbook, *supra* note 43, at 5.

[84] 1989 Rule, *supra* note 3, at 51,654, 51,664, 51,666, 51,668-69, 51,677, 51,682. Risks ranged between 1 in 10,000 and 3 in 10,000. *Id.*

[87] *Id.* at 13.

no risk. In Publication 103, ICRP provides an analysis of the exposure values considered in that analysis. On the basis of model uncertainty and epidemiological evidence, the ICRP recommends a dose-to-risk coefficient of 5% per Sievert (one Sievert is equivalent to 100 rems or 100,000 mrem, see explanation of terms in Attachment A).[88] This coefficient is the basis for current international radiation safety standards, and is considered by ICRP to be "appropriate for the purposes of radiological protection." Although it is based on cancer mortality as the endpoint, it is also approximate for all calculated detrimental effects.

For our risk analysis, we use a dose conversion expressed in terms of millirems or mrem.[89] Translating the 5% risk per Sievert recommended by the ICRP for regulatory purposes yields 5 x 10^{-7} risk per mrem.

The risk assessment submitted as part of this Petition estimates the annual dose for each of the exposure scenarios, summed over the associated years of exposure, to provide a total dose that is then converted to a cancer risk using a dose-to-risk conversion factor of 5×10^{-7} risk per mrem (i.e., 5/10,000,000).

Our use of 5 x 10^{-7} as a conversion factor is consistent with EPA risk assessment procedures.[90] The EPA's 2011 guidance provides cancer risk factors for uniform whole-body exposures of low-dose gamma radiation to the entire population, and reports an estimated 90% confidence interval for cancer mortality of 2.8% to 10% per Gy[91] (i.e., from 2.8 x 10^{-7} to 10 x 10^{-7} per mrem).[92] This range is essentially the same dose to risk conversion range derived by ICRP.

The value we use is also consistent with the perspective of the National Council on Radiation Protection and Measurements (NCRP) (the U.S. organization chartered by the U.S. Congress in 1964 to, among other things, "develop … recommendations about …protection against radiation" (i.e., NCRP uses the same dose to risk conversion factor as in the 2007 ICRP)).[93]

---

[88] International Commission on Radiological Protection (ICRP), The 2007 Recommendations of the International Commission on Radiological Protection, ICRP Publication 103, 55, 87 (2007), *available at* https://www.icrp.org/publication.asp?id=ICRP%20Publication%20103 (2007 ICRP Recommendations).

[89] The mrem is a common unit of radiation dose. In this report, "dose" refers to effective dose, which simply means that when a person is exposed to a uniform radiation (e.g., external gamma radiation), all of the doses to the different organs are weighted by their radiosensitivity and added together. See Appendices 1 and 2 for more detailed discussion of the definitions and application of these factors.

[90] Similarly, the international community has widely adopted the International Atomic Energy Agency (IAEA) determination that 1 millisievert (1 mSv) per year is the acceptable level of radiation exposure (for example, the European Union [EU] regulations). *See* Radiation Protection and Management of NORM Residues, *supra* note 59, at 165. The IAEA and EU determinations are also based on the International Commission on Radiological Protection. 2007 ICRP Recommendations, *supra* note 88, at 55, 97, Table 5, 116, and Table 8.

[91] For practical purposes as to gamma radiation, 1 Gy = 1 Sv = 100 rem = 100,000 mrem.

ED_005285_00000744-00037

The ICRP analysis was also relied upon by the European Union (EU) in selecting its general population acceptable dose level.[94] The EU appointed a group of experts to provide advice on the basic safety standards, taking into account the 2007 recommendations of the ICRP (specifically, ICRP Publication 103 since the ICRP reflected "new scientific evidence and operational experience").[95]

The most recent report of the NCRP (2018) (Report No. 180) provides a detailed discussion of the risks from exposure to ionizing radiation and states that "[*t]he value of 5 % Sv*$^{-1}$ [i.e., 5/10,000,000 per mrem] *is a rounded value for radiation detriment used to inform all the NCRP recommendations regarding stochastic effects*,"[96] (emphasis added).

In summary, the use of the ICRP dose to risk relationship is scientifically sound and supported by many independent governmental entities, including EPA and NCRP. We elaborate further in Appendices 1 and 2. The "conservative" nature of the assumptions underlying the dose to risk relationship and associated uncertainties are discussed below.

For the reasons noted above, the risk estimates derived for PG using the ICRP dose to risk conversion factor are based on a linear relationship between dose and risk for the very low dose exposures derived for this report. Therefore, they are appropriate for use in the Petition and can be relied upon by EPA in its decision making.

D. Calculation of Risk that Corresponds to the RME

This section summarizes the RME doses calculated in the Risk Assessment and explains generally how they are derived.

1. Deriving Dose for the Period of Use

A dose is the cumulative amount of radioactivity absorbed (weighted to take into account the different medical impacts of different types of radiation). The dose is calculated using the RME associated with each scenario.

Duration is specific to the exposure scenario. For a resident, the exposure period is 26 years based on standard EPA guidance.[97] For a road construction worker, the length of exposure is

---

[94] ICRP is an international expert advisory body that offers its recommendations to regulatory and advisory agencies, mainly by providing guidance on the fundamental principles on which appropriate radiological protection is based. The 2007 recommendation was produced "after eight years of discussions, involving scientists, regulators, and users all around the world." 2007 ICRP Recommendations, *supra* note 88, at 3.

five years (based on data from roadway construction projects, DOT manuals, and EPA guidance (see Petition's Risk Assessment (Appendix 2) and discussed in more detail in Appendix 4a: Response to EPA Comments on January 16, 2020, and below in this Petition, Section V). The risk assessment determined that the 3 in 10,000 risk level corresponded to a total cumulative dose of 600 mrem and this value can be used to judge the magnitudes of exposure for each scenario. Table 5 below summarizes the exposure doses calculated in the risk assessment on an annual and scenario basis.

Table 5: Total Dose Summary

Person Exposed	Annual Dose	Years	Total Use Exposure Dose (mrem)
Road Worker	22 mrem	5	110
Truck Driver	18.6 mrem	5	93
Nearby Resident	multiple exposures over 26 years	26	16
Road User	1 mrem	26	28
Utility Worker	0.8	160 hours in 1 year	0.8

2. Converting the Total Use Dose to Risk

Radiation risk for cancer is calculated as the product of the RME exposure dose for each scenario and the dose-to-risk conversion factor. The distance from the road and durations of exposure are key considerations in calculating the total dose risk. While the RME is designed to bound these, most residents would be located at greater distances from the road and/or experience shorter durations of exposure than the RME individual. Thus, actual doses for the populations would be less than those presented here.

As noted above, using a dose-to-risk conversion factor of $5x10^{-7}$ risk per mrem, 600 mrem corresponds to a 3 in 10,000 risk level. From this relationship, one can calculate the risk for a particular dose. The result of the risk calculations are summarized in Table 6 below. The results of the calculations are provided in Appendices 1 and 2 of this Petition.

Table 6: Total Use Dose and Risk Table Compared to Background

RME Exposure Scenario	Total Use Dose (mrem)	Years	Risk From the Use
Road Construction Worker	110	5	0.5 in 10,000
Truck Driver	93	5	0.5 in 10,000
Road User	28	26	0.1 in 10,000
Nearby Resident	16	26	0.08 in 10,000
Utility Worker	0.8	160 hours in 1 year	0.004 in 10,000

(Feb. 6, 2014), *available at* https://www.epa.gov/sites/production/files/2015-11/documents/oswer_directive_9200.1-120_exposurefactors_corrected2.pdf (Update of Standard Default Exposure Factors).

3. Road Construction Worker Risk

Based on the assessments provided in this Petition, the highest estimated RME exposure is for the road construction worker placing road base containing PG that contains radium -226 at 27 picocuries per gram. The exposure dose amounts to ~22 mrem/year (which results in a 110 mrem total dose for the exposure period of five years). This dose corresponds approximately to an incremental cancer risk of 0.5 in 10,000, which is over 5 times less than the PG use risk management level of 3 in 10,000.

4. Risk to the Nearby Resident

In addition to the highest risk individual (a road construction worker), the risk assessment also evaluated the exposure doses and risk to a resident who may live immediately adjacent to the road. Consideration was given to all stages of life from childhood through adult. Exposure depends on distance, with exposures dropping off quickly as distance from the road increases. Nevertheless, for people living immediately adjacent to the road, the exposures and risks are well below the risk management level of 3 in 10,000.

The exposure doses and risks were estimated without considering shielding during the period of construction; shielding was included when estimating doses following construction of the road. Shielding of residents was afforded by the road surface as well as by embankments and other structures that cover the sides of the road base.

The cumulative incremental dose associated with living in a house adjacent to a road with a PG base is 16 mrem and the associated risk is 0.08 in 10,000. These RME exposure dose and risk estimates to nearby residents are well below the EPA risk management levels.

5. RME Risk from the Other Exposure Scenarios

Doses and associated risks for all other RME exposure scenarios (the truck driver delivering the PG, the users of the road, and the utility worker in a trench near the road) are lower than those for the road construction worker (see Table 1 and 6).

6. RME Exposures/Risks, by Definition, are the Highest Exposures

All exposure scenarios have doses and risks that are less than the EPA's risk management levels. The RME risks are constructed to overestimate rather than underestimate the actual risks and this provides confidence for making decisions that are health protective.

Other workers who are more distant from the PG have lower exposures than the construction worker (and, therefore, lower risk). Similarly, most residents living near roadways are exposed to lower risk levels and most PG will contain lower radiation levels used in this calculation. Moreover, the dominant source of dose is gamma radiation which decreases with distance and hence, residents who live more than 50 feet from a road will receive a lower dose (and consequent risk) than the RME at a distance of 50 feet from the edge of the road.

A summary of the risk distribution provided in Table 2, above (which is from Appendix 4a).

In summary, the risk distribution from road construction is negligible, beyond the individuals who are on or immediately beside the road, as assessed in the Risk Assessment document.

7. Comparison to Background

Because radiation is always present naturally, it is helpful to compare the incremental radiological exposures to background levels to provide important perspective. While natural background varies geographically (between states and even within states), a value of approximately 310 mrem a year was used for comparison because it is a widely used national background level. Background radiation varies naturally from ~100 mrem to 1,000 mrem. Thus, the ratio of total use exposure to background will vary depending upon the location of the road (see Table 1 below and provided above). Given the conservative nature of the exposure estimates, these incremental exposures would likely be within the variability of measurement for ambient radiation.

Table 1: Dose, Risk, and Background Summary for All RME Scenarios (repeated for the convenience of the reader)

Receptor	Site	Exposure Duration (years)	Exposure Dose (mrem)	Estimated Cancer Risk	Background Dose from Exposure Duration (mrem)	Exposure Dose Percentage of Background Dose (%)
Reasonable Maximum Exposure Scenarios						
Road Construction Worker	PG in Road Base	5	110	0.5 in 10,000	1550	7%
Road User (Motorist/Bicyclist)	PG in Road Base & Surface	26	28	0.1 in 10,000	8060	0.3%
Truck Driver	PG-containing material for Road Base	5	93	0.5 in 10,000	1550	6%
Nearby Resident	PG in Road Base & Surface	26	16	0.08 in 10,000	8060	0.2%
Utility Worker	PG in Road Base	1	0.8	0.004 in 10,000	310	0.3%
	EPA Cancer Risk Management Goal		600	3 in 10,000	600	

Estimated cancer risk below this goal.

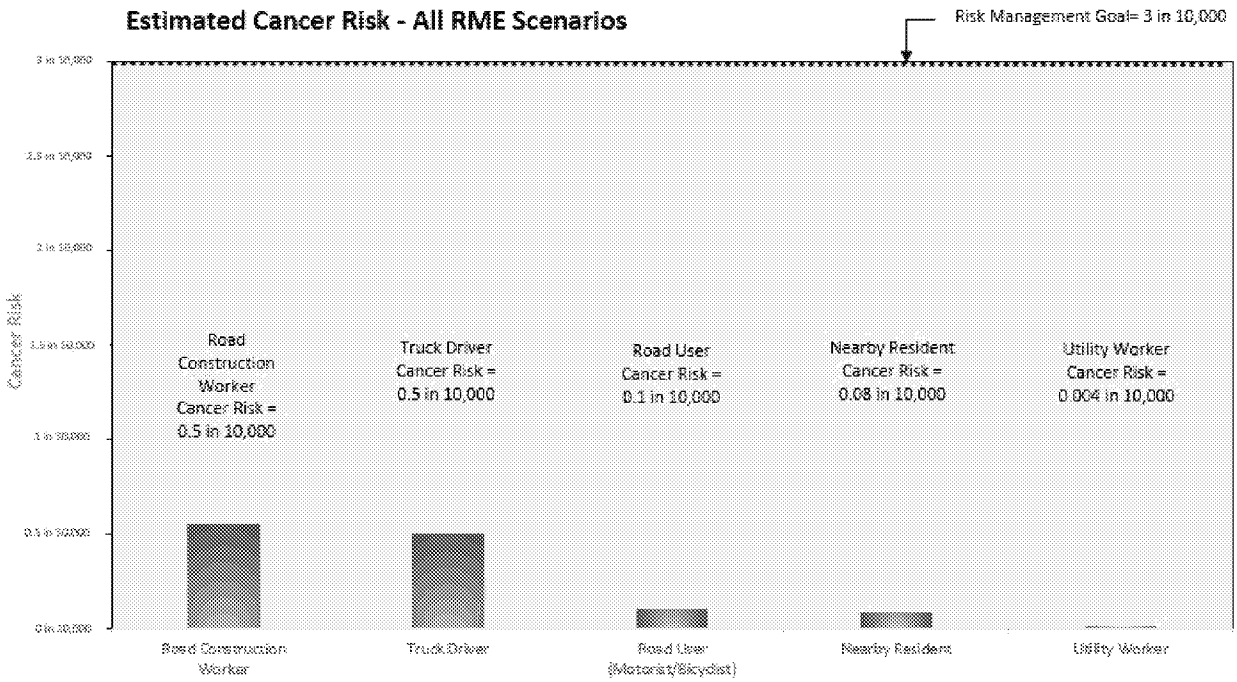
Figure 4: Estimated Cancer Risks



8. Disposition Scenario

The EPA PG use regulations require an assessment of the risk from the ultimate disposition of PG for any product in which the PG is incorporated.[98] The RME for the ultimate disposition of a new road constructed with PG is that it serves as an established part of municipal (county, state, or federal) infrastructure and as such would require periodic repair and expansion as needed. Road maintenance activities include removing the surface, grinding and reusing or disposing of the materials consistent with federal, state, and local regulations. Exposures and risks associated with maintenance of roads and reuse of construction materials are expected to be comparable to or less than those detailed in the risk assessment for road construction (Appendix 4a: Response to EPA Comments on January 16, 2020).

9. Extreme Hypothetical Reclaimer Requested By EPA (> RME)

Our evaluation is that, in light of current policies and known constraints on future land use for public infrastructure, a hypothetical reclaimer scenario does not represent a reasonably foreseeable future use for inclusion in the risk analysis for this Petition (Appendix 4b: Responses to Second Set of USEPA Questions - Reclaimer).[99]

The reclaimer scenario used in the 1992 BID Risk Assessment as a reasonable disposition scenario (without any explanation or scientific support) was the assumption that a house is built

[98] 40 C.F.R. § 61.206 (a)(8)(1).

[99] Memorandum from TFI to Lee Veal, Director, Radiation Protection Division, U.S. Environmental Protection Agency (April 24, 2019). This detailed memorandum explains the reasons that the Reclaimer Exposure Scenario is not a RME.

on the roadbed at some future time after the road is closed and the road surface has crumbled and been removed. (EPA 1992 BID, p. 4-10). This was not an RME disposition scenario then, nor is it realistic now.

First, a diligent search has not found any documentation of paved roads being abandoned and residential housing being constructed immediately on the abandoned pavement.[100]

If there are any examples, they are rare (i.e., 90th percentile or above) and beyond the RME exposure.

Second, there are many institutional and legal obstacles to abandoning roads, much less constructing homes on them. All public roadways and associated rights of way are owned and operated by the government and by law are dedicated to public use. All of these public roadways are subject to governmental jurisdiction with zoning and land use requirements that support continued roadway use. For example, to abandon a road in Florida, there must be notice of the intent to abandon the road, a public hearing, a duly adopted and entered resolution of abandonment, and notice of the abandonment resolution.[101] A road cannot be abandoned if it is a public road and is used by the public (see Florida, Idaho, Louisiana, Alabama and several other state laws). Some states, such as Alabama, have a statutory preference against abandonment. Federal highways can be decommissioned, consistent with a robust public process. In the case of the Pennsylvania Turnpike, part of it was converted to a bike path.[102] Similarly, the West Side highway in New York City was converted into an urban park, not housing. In any event, roads built with PG will be constructed and and maintained consistent with state and federal laws. Any effort to abandon and repurpose these roads, including for development, also must be consistent with federal and state statutes and local ordinances.

Similarly, some county roads are abandoned to become state roads and some state roads are abandoned to become federal roads. Transfer of a state road to the federal highway system or vice a versa is not relevant since the road remains a road.

Maintaining public roadways and associated rights of way into the future is consistent with current trends in community plans to maintain and expand roadway infrastructure and utility services (buried within right of ways) and to provide access (e.g., ingress/egress to surrounding parcels). Converting a roadway to a residential property must be done consistent with state laws and would complicate or eliminate access to surrounding parcels in addition to the redeveloped residential property[103] and is not a realistic assumption. Furthermore "[v]acating a road that

---

[100] Abandonment of unpaved roads is not relevant since we are not seeking to approve of the use of PG on unpaved roads. This factor and the other factors in the text are summarized from the Petition's Risk Assessment (Appendix 2), Responses to Second Set of USEPA Questions – Reclaimer (Appendix 4b), and the legal research on the legal obstacles on abandonment of roads provided in the Revised Petition.

[102] *Abandoned Stretch of Turnpike in PA*, ConstructionEquipmentGuide.com, Jan. 11, 2006, *available at* https://www.constructionequipmentguide.com/redirect/6495?story=6495.

[103] *See* James J. Fazzalaro, Local Road Abandonment and Abutting Property Owners, OLR Research Report, 2003-R-0897 (December 24, 2003), *available at* https://www.cga.ct.gov/2003/olrdata/tra/rpt/2003-R-0897.htm.

eliminates or substantially diminishes access for abutting property owners may likely amount to a taking,"[104] which is another disincentive to abandonment.

Third, economics dictates that if an abandoned road is transferred to a housing association, the land will remain as a road maintained by the housing association. More generally, since storm drains and often utility lines are placed along rights of way, the abandoned road is more likely to be used as a private road, not housing. While it is not impossible for a house to be be built on an abandoned roadway, it is certain to be extremely rare.

Fourth, the sustainability of roads and the use of road construction materials are key aspects of guidance and plans for roads under the jurisdictions of the Federal Highway Administration and state Departments of Transportation. The in-place abandonment of municipal infrastructure and allowance for construction of residences on top of these abandoned roads runs counter to sustainable infrastructure projects involving road construction. In any case, the construction activities required for road maintenance result in less exposure than during the original road construction (i.e., the construction activities on scale).

Thus, road abandonment, and the construction of a home on the abandoned road is not an RME exposure and, therefore, is not an ultimate disposition scenario. The fact that this extreme exposure scenario corresponds to a risk below the EPA risk management level confirms that the lesser exposure in the ultimate disposition scenario need not include a numerical risk assessment.

Finally, normally, the removal of unused PG during the road construction project is not an appropriate ultimate disposition because from an economic perspective, it is unreasonable to purchase more PG than will be used. Appropriate planning will ensure that all PG is mixed with soil (in a one to one ratio) and used in the road. In the rare case where there is unused PG, it can be used in another ongoing road construction project or returned to the PG source to be stored on a PG stack. Thus, a Reclaimer Exposure Scenario should not be utilized to determine whether to approve the use of PG for road construction.[105]

But, since EPA requested that the risk analysis include the extreme hypothetical reclaimer scenario, it is summarized below (see Petition's Risk Assessment and Appendix 4b: Responses

---

Florida Office of the Attorney General, Counties, roads and streets, dedication, vacation, Advisory Legal Opinion – AGO 78-118 (Sep. 27, 1978), *available at* http://www.myfloridalegal.com/ago.nsf/Opinions/1F43FA7B5F1C0AF18525659300627D32. [104] Thomas Ruppert, Erin Deady, Jason M. Evans, & Crystal Goodson, Legal Issues When Managing Public Roads Affected by Sea Level Rise: Florida, 5 (Spring 2019), *available at* https://www.researchgate.net/publication/332528839_Legal_Issues_When_Managing_Public_Roads_Affected_by_Sea_Level_Rise_Florida.

[105] As a practical matter, if a risk assessment uses extreme enough assumptions, the calculated risk will exceed any risk management safe level. Thus, realistic but high-end RME are used.

ED_005285_00000744-00044

to Second Set of USEPA Questions – Reclaimer, which responds to the technical issues relating to the extreme Reclaimer scenario). As part of the hypothetical reclaimer scenario, the exposure assumptions still need to be RME assumptions. The duration of exposure is 26 years (because that is EPA's RME residential exposure (i.e., the 90th percentile of exposure)).[106] Normal house construction practices were utilized, such as use of non-PG fill to grade the land (which mixes the PG with non-PG soil), the use of vapor barriers and a slab beneath the house, and the like (as described in Appendix 4a: Response to EPA Comments). The annual total radiation dose is 3 mrem, which converts to 78 mrem over 26 years (the total use dose). The resident reclaimer scenario requested by EPA is an extreme exposure duration. Nonetheless, this risk (which is higher than an RME risk) corresponds to about a 0.4 in 10,000 risk, still below the PG use risk management level of 3 in 10,000.

Even this extreme hypothetical scenario does not result in exposures and risks that exceed the EPA risk management level of 3 in 10,000. It must be emphasized that the use of the reclaimer scenario does not mean it is a foreseeable ultimate disposition. In any event, the fact that this extreme exposure scenario presents a risk below 3 in 10,000 demonstrates that any conceivable RME scenario related to ultimate disposition will meet the EPA's risk management level.

E. Groundwater Pathway Screening Analysis

EPA's PG Petition guidance suggests that the Petition should address other potential pathways of exposure, such as the ground water pathway, if they are relevant.[107] The Petition used a screening analysis to address these pathways and, where appropriate, referenced EPA's prior evaluations. A conservative screening level analysis generally is used to determine at an early stage that no further analysis is warranted.

1. Radionuclides in Groundwater

EPA performed extensive modeling of the likely migration of radionuclides in a 1992 assessment of the risk from PG used in agriculture and road construction. Neither concluded that the groundwater pathway supported restrictions on the use of PG.[108] EPA's risk assessment determined in 1992 that "no radionuclides are calculated to reach the onsite well via the groundwater pathway" nor are any "radionuclide calculated to reach the off-site river or well via groundwater."[109] (see SENES 1997[110] which also examined the potential for impacts to

---

[106] 90th percentile exposure means that 90% of the exposed population has that level of exposure or less and only 10% of the population has higher exposure. EPA published its Superfund Land Use Directive in 1995 (Land Use in the CERCLA Remedy Selection Process, *supra* note 52) and reaffirmed the policy in 2001 (EPA, Reuse Assessments: A Tool To Implement The Superfund Land Use Directive, OSWER 9355.7 - 06P (June 4, 2001), *available at* https://nepis.epa.gov). EPA's 1995 Land Use Directive acknowledges that "EPA has been criticized for too often assuming that future use will be residential" and identifies several evaluation factors to identify reasonably anticipated future land use, such as current land use, zoning laws and maps, community master planning, population growth patterns and projections, accessibility to existing infrastructure, site location, federal/state land use designation, and others.

[107] EPA PG Workbook, *supra* note 43, at 10.

[108] EPA 1992 BID, *supra* note 15, at Chp 4. See discussion in Appendix 2.

[109] EPA 1992 BID, *supra* note 15, at 4-31, 4-34, Scenario 8, Tables 4-5, 4-18, n. C, Scenario 11, among other sources.

ED_005285_00000744-00045

groundwater and surface water pathways). These studies found no realistic potential for impacts to these pathways, i.e.:

> No radionuclides are calculated to reach the on-site well via the groundwater pathway for almost 10,000 years, or the off-site river or well for more than 100,000 years because of groundwater velocities and retardation factors.[111]

The radionuclide risks were found to be negligible. The TFI consultants agree with these prior assessments and no additional evaluation was deemed necessary. No monitoring data reviewed indicates significant groundwater impact from radionuclides. The Response to EPA Comments on January 16, 2020 (Appendix 4a) provides a more detailed explanation of the extremely low risks from radionuclides in groundwater, which was the basis from the Petition's Risk Assessment not duplicating these conservative calculations.

2. Screening Evaluation of the Potential Impact of Non-Radionuclides in PG

The EPA PG Guidance states:

> [A petitioner] "must provide information on the other toxic or hazardous constituents of the waste…to assure that the proposed use does not cause non-radiological risks to human health and the environment."[112]
>
> To the extent the phosphogypsum is land applied or will remain in place following the test, the risk assessment must examine other potential pathways of exposure, in particular with respect to ground-water and surface water. Consideration of multiple pathways, particularly pathways associated with ground water, are consistent with our review of alternative uses as found in the 1992 rulemaking on phosphogypsum.[113]

Despite this, EPA did not include an assessment of the impact of metals in its review of alternative uses of PG in 1989 or 1992 (see Appendix 3).

However, EPA requested that TFI perform screening analyses of the potential impact of direct contact with PG by road construction workers, and evaluate potential metals leaching on ground and surface water quality. Thus, these assessments were performed and appear in Appendix 3.

These analyses confirm that PG is "safe" for worker handling with respect to non-radionucldes as well. Road construction workers were assumed to come into direct contact with PG (incidental ingestion, inhalation, and dermal contact). The PG concentrations were then compared to health-based screening levels. The chemicals in PG were found to be either a low risk or present at background levels.

[112] EPA PG Workbook, *supra* note 43, at 9.

[113] *Id.* at 12.

Appendix 3 contains an assessment of the potential for metals to leach from a roadbed using PG. The design of new roads affects the potential for exposures by creating a degree of isolation of the base layer from the environment. The PG in the proposed alternative use is placed above the water table and underneath the road's paved surface. Additionally, the roads are sloped to drain precipitation.[114] This further limits water contact with the PG isolated within the base layer. Thus, for purposes of the Petition, leaching of PG to groundwater or surface water is likely not a complete exposure pathway of concern for roadbed use and therefore no more detailed risk assessment is needed based on the typical screening level approach.

The metals concentration in the road base (and, therefore, the amount that is leached) is only 50% of the concentration of metals in PG because the PG is mixed with soil, sand, or aggregate (see Appendix 3).

The literature shows limited leaching directly from PG. For example, a 2011 University of Florida study by Mostary (2011) took twelve samples and performed comprehensive leachability testing for PG sampled from one stack in Florida (see Appendix 3). In this study, there were no exceedances of EPA's primary drinking water standards in synthetic precipitation leaching procedure (SPLP) testing and no exceedances of Resource Conservation and Recovery Act (RCRA) toxicity characteristic leaching procedure (TCLP) limits (see Appendix 3). The TCLP and the SPLP tests extracted relatively similar metal concentrations (except calcium).

Another apt risk comparison for the metals in PG are the federal and Florida land application limits for biosolids[115] (see Appendix 3). EPA limits were based on a risk assessment for 14 exposure pathways, including groundwater (Table 6 in U.S. EPA 1995 for a guide on the Part 503 Rule.).[116] For metals in biosolids, EPA found that leaching into groundwater or runoff into surface waters were <u>not</u> limiting pathways (see Appendix 3).

For the purposes of an EPA NESHAP review, it is important to understand and consider the fact that groundwater protection is primarily governed by state law and is considered under federal and state highway guidance. For example, the Florida Department of Transportation's Standard Specifications For Road And Bridge Construction states roads must: (a) "[p]rovide erosion control measures where work is accomplished in conjunction with the project, to prevent erosion, pollution of water, detrimental effects to public or private property adjacent to the project right-of-way and damage to work on the project;" (b) "[d]o not drive in, operate, or place construction equipment or materials in surface waters, wetlands, groundwater, or property beyond the project limits without permitted authority for permanent or temporary impacts; and (c) [d]o not allow water that does not meet state water quality standards or does not meet the permitted criteria to exit the project limits.[117] That is, metals impact on groundwater will and should be determined at the local level.

[116] EPA, A Guide to the Biosolids Risk Assessments for the EPA Part 503 Rule, EPA/832-B-93-005 (1995), *available at* https://www.epa.gov/sites/production/files/2018-11/documents/guide-biosolids-risk-assessments-part503.pdf.

[117] Florida Spec Book, *supra* note 23, at 131.

The fact that materials utilized to construct roads can impact the environment has been reported by the NAS,[118] states,[119] and other federal agencies,[120] and applies to all road construction material, not just PG. States provide comprehensive guidance on roadway design.[121] Thus, regardless of the source of the road construction material, the federal, state, and local road building agencies will assess the environmental and physical characterization to determine whether there is an impact from utilizing material A versus material B and decisions on how to mitigate any impacts is within the discretion of these agencies.

Lastly, the footprint of a road on the landscape is very small compared to agricultural lands upon which biosolids and amendments with many higher allowable metal concentrations than those in PG are permitted for continuous use (see EPA 1992 BID). The smaller footprint and lower likelihood of leaching from a constructed road compared to an agricultural field indicates that the influence on groundwater from PG in the road is likely to be comparatively very small. The amount of PG in road base is expected to be negligible in comparison and thus can be used safely in road construction given the lower metals content in PG and the smaller footprint and confinement of the base layer above the water table.

In summary, the presence of other substances that are not radionuclides in PG is unlikely to present an unacceptable worker exposure or adversely impact groundwater or surface water quality. The leaching pathway is likely not a complete pathway of concern for the PG use in road construction proposed in this Petition.

F. Risks From Other Pathways

The Response to EPA Comments on January 16, 2020 (Appendix 4a) contains an explanation of the low risks from other pathways (air, ingestion of food from a garden, etc.) and the rationale for not duplicating the risk assessment on these pathways from the 1992 BID risk assessment.

G. Comparison of TFI Risk Assessment and Screening Evaluation with EPA's 1992 EPA Background Information Document (BID) Risk Assessment

Appendix 2 performed a very "high level" and preliminary overview of the main differences that we could readily identify between the dose and risk results provided in EPA's 1992 BID and those previously discussed in this report. The following is a list of comparisons:

- A 1:1 dilution of PG with soils (higher PG to soil than EPA's 1:2 PG to soil in 1992. Appendix 2, 1992 BID page 4-9).

- A road thickness of 0.25 m (the same as in 1992).

- The current risk assessment considers the same receptors as EPA did in 1992 as well as two additional receptors suggested by the EPA, namely, the truck driver transporting PG to the construction site and a utility worker who works some time in a trench cutting across a road constructed with PG.

- For the road construction worker, the EPA considered workers standing on the road base and unshielded, as was also assumed for the current risk assessment.

- The current risk assessment assumes a worker moves around over the road surface and is exposed at the average of the gamma fields at the center and edge of the road. While not fully clear, the EPA in 1992 may have assumed a worker was always in the center of the road which would largely account for the difference between gamma doses estimated in 1992 and now.

- The road user is assumed in both cases to drive on a road with a PG base and a cover (in 1992 asphalt or cement) and in the present analysis, for purpose of illustration, concrete road surface was assumed. Only annual dose and risk are available from the 1992 risk assessment. The 1992 EPA risk assessment used a 0.6 shielding for the road user, but rather than determine the degree to which vehicles have changed in the amount of metal in the under carriage of cars, the current risk assessment takes no credit for shielding provided by the vehicle that would provide some level of shielding which is a conservative assumption and could reasonably be considered.

- The dose to the nearby resident is dominated by exposure to gamma radiation which decreases rapidly with increasing distance from the edge of the road. The 1992 risk assessment assumed the nearest resident would be at 100 meters (approximately 328 ft) from the edge of the road. The current assessment considers the RME exposure scenario to be a resident whose home is located a distance of 50 feet from the edge of the road (an urban resident whose home is at 20 feet from the edge of the road is also calculated to illustrated the change in exposure levels with distance).

- The 1992 BID mentions the presence of metals, but did not consider any substances other than radionculides in the 1992 risk assessment. The current Petition includes a metals screening evaluation to justify the fact that a quantitative risk assessment is not warranted.

- The EPA BID risk assessments considered a reclaimer scenario with exposures from gamma radiation and radon, in which the surface is removed and a house is directly built upon PG, and a resident lives in the house for 70 years (see Petition's Risk Assessment and Appendix 4b for a full review of the so called reclaimer scenario).

    - At EPA's request, this Risk Assessment calculated this reclaimer scenario, even though such a scenario is an extreme hypothetical case that is not a RME exposure. Both the 1992 and present calculation assume the surface is removed, but the current assessment takes into account the necessary construction site preparation and grading, which reduces the thickness and to a lesser degree, the concentration of residual road base construction activity that would be necessary to construct a house.

    - The 1992 BID does not indicate how the risk from radon was calculated (dose from radon was not reported in the 1992 BID).

    - The 1992 BID assumed 70-years residency and the current assessment uses EPA's current RME for duration living in a residence of 26-year residency (the upper 90th percentile) (see more in depth discussion in Sections I(B), III(A)(2), and IV (D)(9), above). Even the 1992 BID risk assessment used 26 years as the duration a person might reside in the house. Thus, the 70-year residency for the reclaimer scenario in the 1992 BID appears to be inconsistent with the residency lengths used by EPA in other parts of the 1992 as well as current EPA guidance.

    - The current assessment also assumes a 6 ml poly layer which is standard as a vapor barrier in current home construction.

    - Both the 1992 BID Risk Assessment (at Table 4) and the Petition's Risk Assessment calculated the risk based on an assumed concentration of radium (226) (26 pCi versus 27 pCi/g).[122]

These comparisons demonstrate the upper bound nature of the risk assessment. Actual doses and risks are likely to be lower.

V. RISK MANAGEMENT DECISION

TFI has provided information required by EPA[123] necessary for completing the agency's evauation and determination that use of PG in road construction may be deemed at least as protective of human health as disposal on a stack. Risk management factors favor approving the use of PG for road construction. The petition and supporting risk analysis demonstrates that this use can be advanced safely. Justifications for this determination include:

The Risk Management limit of 3 in 10,000 is consistent with other NESHAP risk limits.

---

[122] The 1992 BID Risk Assessment include in the table the risk from a range of radium (226) concentrations.

[123] Information requirements at 40 C.F.R. §§ 61.206(b) (1), (2), (6), (7), (8), and (9) for EPA approval based on a risk assessment determination and conditioned upon receipt of information requirement (3), (4), (5), and (10).

- The highest Reasonably Maximum Exposure (RME) for the use of PG in road construction, 0.5 in 10,000 (0.5 in 10,000 is 5 in 100,000), is well below the NESHAP radionuclide risk management limit of 3 in 10,000.

- For ease of calculation, this Risk Assessment used a nominal average radioactivity level in PG of 27 pCi/g. By "nominal average" we mean this is the average radioactivity level we used in our initial calculation. This number is reasonable and is similar to numbers EPA previously used.

- Once the risk from the initial calculation is determined, EPA can then estimate the risk from higher and lower radioactivity levels. For example, if the average radioactivity level for a stack is (13.5 pCi/g, then the risk is one half of that calculated for 27 pCi/g).

- At EPA's request, TFI members recently sampled PG from multiple gypstacks (Appendix 5). This report confirms that the existing data supports the use of the PG stacks in the U.S for use in road construction. In summary, the average radioactivity level for each stack was significantly lower than 27 pCi/g.

- Furthermore, the risk assessment performed for this Petition demonstrates that 27 pCi/g corresponds to a cancer risk of 0.5 in 10,000 for the highest RME use of PG in road construction (i.e., the road construction worker), therefore the risk from these stacks is less than 0.5 in 10,000. Based on the risk assessment performed for this Petition, EPA's PG risk management safe risk level of 3 in 10,000 corresponds to a radium (226) concentration in the PG of 148 pCi/g (see Sections I(B) and III(B)(3) and Appendix 2). Thus, PG materials in TFI's member's stacks may be safely used as road construction material. It is extremely unlikely if not impossible for random variation in the PG radioactivity levels to exceed an average 148 pCi/g, the radioactivity level that corresponds to a 3 in 10,000 risk management level. EPA performed extensive modeling of the likely migration of radionuclides from PG used in road construction in a 1992 assessment discussed below. The EPA concluded that the radionuclide doses from the groundwater pathways are all negligible. EPA's assessment demonstrates that the radionuclide risks were found to be zero.

- Screening evaluation of the potential impact of metals in PG shows that PG can be used safely by workers in road construction. Paving limits direct contact by the community and also limits water contact with PG isolated in the base layer.

- Care has been taken in the assessment process to manage scientific uncertainties by choosing values and approaches that are likely to overestimate rather than underestimate risks. These result in an RME value, which serves as a reasonable upper bound on the risk distribution and is a readily accepted approach for representing maximum exposures (see Appendix 2). It also provides insight into risks to the population. RMEs overestimate risks for highest exposure situations such that actual risks would be lower.

- For perspective on exposure magnitudes, radiation levels from the use of PG are compared to naturally occurring background. Each exposure scenario has incremental radiological dose that are well below naturally occurring background levels. Exposures

ED_005285_00000744-00051

to the public using the road or living immediately adjacent to the road are likely to be indistinguishable from the natural variability in background.

- There are naturally occurring background radiation and metals in other non-PG construction material including coal ash, fly ash, bottom ash, and other common construction materials. These materials have been deemed safe to use in road construction and other applications. Similarly, this Petition demonstrates the same is true for PG. The use of PG for road construction is consistent with EPA policy on recycling of wastes and waste residuals.The use of PG for roadway construction provides a net economic benefit.

- Approval of the use of PG for road construction is consistent with the Administration's regulatory reform policies.

A. Overview

The regulatory decision to approve a new use for PG is a risk management decision that is assigned to the Assistant Administrator for Air and Radiation. Risk management decisions involve weighing the results of a risk assessment with "the results of other technical analyses and nonscientific factors, to reach a decision about the need for and extent of risk reduction to be sought in particular circumstances and of the means for achieving and maintaining that reduction."[124]

This Petition and its Appendices provide the facts and science required to approve this Petition. This subsection applies these facts and the science to EPA's risk management factors and explains TFI's position that approval is appropriate.

B. The Risk Management Level of 3 in 10,000 is Consistent with Other NESHAP Goals

The EPA Office of Air and Radiation policy is to make a case-by-case decision concerning the acceptability of the risk from exposure to radionuclides.[125] However, the PG risk management limit of 3 in 10,000 is consistent with other typical EPA risk management decisions.

C. The Highest RME Risk Scenario for the Use of PG in Road Construction is Below the NESHAP Radionuclide Risk Management Goal of 3 in 10,000

This Petition demonstrates that the risks of using PG material in constructing roads satisfy the risk management goal for approved alternative uses of PG. In fact, the risk of PG in road construction is well below the risk management goal of 3 in 10,000.

---

[124] Institute of Medicine, Environmental Decisions in the Face of Uncertainty, Box 2-1 (2013), *available at* https://www.ncbi.nlm.nih.gov/books/NBK200844/box/box_2_1/?report=objectonly (Uncertainty in Environmental Decisionmaking).

[125] 1989 Rule, *supra* note 3, at 51,564.

The risks from all exposure scenarios were calculated, but the highest RME risk is calculated for the road construction worker who is involved with paving the road with PG that is mixed with soil (i.e., a cancer risk of 0.5 in 10,000, lower than the PG alternative use risk management goal of 3 in 10,000). EPA has long concluded that 3 in 10,000 is the equivalent of the risk from the existing PG stacks, so this alternative does not present a meaningful difference in the risk from the existing stacks. The focus is on the road construction worker since the risks from all other exposure scenarios fall below 110 mrem during road construction use and are of lower risk, although the road worker's risk falls within EPA exposure limits as well.

The vast majority of road construction workers have much lower risks than those calculated in this Petition. Highway construction workers not directly working on the road are located further from the PG and the associated risks are lower.

The risk calculation for the highest RME for a worker placing road base assumes that the PG emits 27 pCi/g exposure for five years. Based on the preliminary data on radiation levels from PG stacks, the average level of radioactivity from the PG material in each sampled stack is less than the nominal 27 pCi/g used in the risk assessment, thus, the risk from these sampled stacks is even further below the EPA risk management safe limit of 3 in 10,000 risk level. The calculated risk is scalable, i.e., if the radioactivity level in a stack is 13.5 pCi/g, the risk is one half of the risk calculated for the nominal radioactivity level of 27 pCi/g (i.e., the 13.5 pCi/g stack corresponds to a 0.28 in 10,000 risk level, significantly lower than the EPA PG risk limit of 3 in 10,000). On average, the RME exposure and the dose to risk conversion for road construction workers using PG are likely to overestimate risk.

Similarly, the highest RME to a resident living near a road (the resident lives in a home located 50 feet or more from a road for 26 years) assuming the PG contains 27 pCi/g is approximately a 0.08 in 10,000 cancer risk, again, well below the PG use risk management goal of 3 in 10,000. Most residents living near roadways are located further than 50 feet from the edge of the road, and the RME exposure and dose to risk conversion are likely to overestimate risk.

The reclaimer scenario is not a RME since it is such a rare potential event, and should not be used in the risk management decision. Nonetheless, the risk assessment report calculated a risk using RME-type exposure input below the PG use risk management goal of 3 in 10,000.

D. Science Policy Assumptions and Uncertainties are Taken into Account in the Final Risk Management Decision

1. Overview

Each of the factors EPA considers in its risk management decision has sensitivities, variabilities, and uncertainties. EPA specifically considered uncertainties and other nonrisk factors in its 1989 and 1992 decisions on acceptable alternative uses of PG.[126]

A recent NAS report recommended incorporating an uncertainty analysis, which was broadly defined to include sensitivities, variability, and various other uncertainties, into EPA

[126] EPA PG Workbook *supra* note 43, at 5.

decisions.[127] This NAS report recommends that an "uncertainty analysis" be "designed on a case-by-case basis."[128] EPA considered uncertainties in previous risk calculations and decisions concerning alternative uses of PG.[129] However, combining RME with the inherent uncertainties in the dose to risk conversion factors can yield risks that are overly conservative compared to actual risks.

Science policy influences both the exposure calculation and the cancer potency and noncancer risk factors that convert the exposure to risk. The EPA decision makers and the public need to understand how policy influences the risk calculation. Put simply, regulatory risk is not the same as actual harm. Unduly conservative risk calculations do not serve the public, since they divert limited resources to issues that present less risk. Science policy based on accumulations of conservative assumptions, including extra layers based on uncertainties, can distort risk estimates and undermine the value and credibility of risk management decisions.

2. Measurement Variation and Uncertainty

Each calculated risk depends upon how sensitive the calculation is to changes in the measurements and input values used in any risk assessment. Risk is assumed to be linearly proportional to dose and the length of exposure. For example, if the concentration of radionuclide in PG increases by 10%, the dose (and, therefore, the risk) increases by 10%. Similarly, if the length of exposure increases by 20%, the total dose increases by 20%. See Section IV, above for a discussion of the variation.

3. Variation by Location

Some of the inputs to risk assessments naturally vary. For example, the average radioactivity level in PG stacks depends upon the source of the phosphate ore and other site specific factors. This risk assessment assumed average radioactivity levels of 27 pCi/g. However, the average level of radioactivity in PG stacks in the TFI 2019 sampling varied from 6.3 to 27.9 pCi/g and data from 1988 had average stack concentration of 34 pCi/g (see Sections I(B), III(B)(3), and Appendix 5). Even levels of 148 pCi/g are safe.[130] Again, dose is directly proportional to the radioactivity level.

4. Variation Due To Design Facts

The Risk Assessment was developed to examine a conceptual road design, to provide an estimate of the upper end RME risks associated with PG use in roads. This approach is appropriate because it is impractical to perform a risk assessment that uses different values for every conceivable road design. Neither the 1989 nor the 1992 BID risk assessment considered every conceivable road design.

---

[127] Uncertainty in Environmental Decisionmaking, *supra* note 124, at 5.

[128] *Id.*

[129] EPA PG Workbook, *supra* note 43, at 5.

[130] Based on the risk assessment, PG with radiation levels a couple of times greater than 27 pCi/g may still be utilized for road construction. In fact, an average radiation level of 148 pCi/g corresponds to EPA's risk management goal of 3 in 10,000.

The following factors utilized to minimize the impact of any uncertainties are discussed in the Response to EPA Comments on January 16, 2020 (Appendix 4a).

- The 2019 radiological testing demonstrates that no individual radium (226) concentration the exceeds 35 pCi/g radium (226) concentration requested as a concentration limit and the measured stack averages are well below the 3 in 10,000 safe risk level (i.e., a radium (226) concentration of 148 pCi/g).

- The EPA 1992 BID assumed a 1:2 dilution of PG with soils for a road base concentration of 10 pCi/g. The Petition's Risk Assessment utilized less dilution (1:1 PG:soil).

- The EPA 1992 BID assumed the road base was 0.25 m thick and 30 feet (9.15m) wide and that the road base is covered with a 0.12 m (5 in) thickness of asphalt. The Petition's Risk Assessment utilized a road thickness of 0.25 m (the same as in the EPA 1992 BID).

- The EPA 1992 BID assumed PG in a concrete road incorporates 15% PG by weight and 0.12 m thick (5 in) and 24 feet wide (7.32 m). The Petition's Risk Assessment reviewed road base design criteria and concluded 15% was a high-end criterion.

- The EPA 1992 BID used exposure to the critical population group member (nearby resident 100 m (i.e., 328 ft) from the edge of the road). The Petition's Risk Assessment calculated the radiation levels at 50 feet from the edge of the road.

- The current risk assessment assumes a worker moves around over the road surface and is exposed at the average of the gamma fields at the center and edge of the road, which is more reasonable than assuming a worker never moves for 5 years. The stationary worker is not realistic or reasonable, therefore it is not an RME.

- The 1992 EPA risk assessment used a 0.6 shielding for the road user, but rather than determine the degree to which vehicles have changed the amount of metal in the under carriage of cars, the current risk assessment takes no credit for shielding provided by the vehicle which would provide some level of shielding which is a conservative assumption and could reasonably be considered.

- The current risk assessment considered two receptors beyond those considered in the 1992 BID (truck driver and utility worker).

5. <u>The Influence of Exposure Policies</u>

It is well settled that exposure is not sufficient to support regulation unless there is a significant risk.[131] Because empirical data are often not available, a 2013 National Academies of Science

[131] "When the administrative record reveals only scant or minimal risk of material health impairment, responsible administration calls for avoidance of extravagant, comprehensive regulation. Perfect safety is a chimera; regulation must not strangle human activity in the search for the impossible. *Indus. Union Dep't. v. API*, 448 U.S. 607, 642 (1980). *See Natural Resources Defense Council v. EPA*, 824 F.2d at 1164-65.

(NAS) report noted that EPA's risk assessment policies and practices rely heavily on default options or generic approaches.[132] These approaches can introduce high levels of uncertainty into risk assessments.

As noted above, the "intent of the RME is to estimate a conservative exposure case (i.e., well above the average case) that is still within the range of possible exposures."[133] A NAS Committee reviewing EPA's regulation of technologically enhanced naturally occurring radioactive material (TENORM) recommended that EPA "should use exposure and dose risk assessments that are 'reasonably realistic'" in developing standards for exposure to the various types of low level naturally occurring radiation.[134] The Committee defined "reasonably realistic" as "not....intended to greatly overestimate or underestimate actual effects for the exposure situation of concern" and EPA agreed with the Committee's recommendations.[135] Thus, by definition, RME exposures should be intentionally set at levels that are at the high end, but not an extreme worst case.

The use of defaults has been criticized by independent commentators for: (a) "lack of an adequate scientific basis;" (b) the fact that default "can mask the uncertainty;" (c) observations that defaults can be "overly conservative;" (d) the fact that cumulative impact of uncertainties is not well defined; and (e) concerns "whether there is any basis for believing that the upper-bound estimate for one substance has the same relation to the 'true' risk as it does for another substance."[136]

The Response to EPA Comments on January 16, 2020 (Appendix 4a) summarizes and expands on the discussion of the reasons that the RMEs are supportable and consistent with EPA policies and the recommendations of learned advisory bodies.

6. Risk Factor Policies and Uncertainties

EPA has long utilized (and courts have long upheld) the principle that a 1 in 10,000 risk level is "safe." As a unanimous *en banc* ruling of the Court of Appeals for the District of Columbia Circuit candidly noted, the basis for claiming harm from exposure to chemicals at extremely low environmental levels is more a function of "the rules of arithmetic rather than because of any knowledge" and there was "no particular reason to think that the actual line of the incidence of

[134] EPA Report to Congress Re: TENORM, *supra* note 75, at 15.

[135] *Id.* citing the NAS Report at p. 245. "If high-end values are chosen for every exposure factor, then the resulting exposure estimate may no longer be consistent with the RME and may exceed the realm of possibility altogether." ITRC, Decision Making at Contaminated Sites, *supra* note 10, at 6.1.1.

[136] Uncertainty in Environmental Decisions, *supra* note 124, at 58. The RME and other factors utilized in the risk assessment are documented in the literature (*see* RESRAD documentation, EPA guidance or as justified in the various Appendices to this Petition).

harm is represented" by the assumption selected by EPA.[137] This acknowledgment is also apt for the risks from radionuclides.

The 2013 NAS noted that:

> EPA originally selected the linear, no-threshold default as a "conservative" or "health-protective" policy choice because it assumes that there is no dose below which risks are not increased. It is likely to generate the highest, or upper-bound, risk estimate consistent with the data; the actual risk almost certainly will not exceed the upper bound and will likely fall below it.[138]

Use of the International Commission on Radiological Protection (ICRP) value (proposed by the international institution whose purpose is to provide such advice) is supported by several factors:

First, ICRP is an expert advisory body that offers its recommendations to regulatory and advisory agencies, mainly by providing guidance on the fundamental principles on which appropriate radiological protection is based. The 2007 recommendation was produced "after eight years of discussions, involving scientists, regulators, and users all around the world."[139]

Second, the Petition's use of the ICRP dose to risk conversion factor is consistent with EPA's radiation risk assessment factors and procedures. For example, the EPA 2011 radiation guidance[140] provides cancer risk factors for uniform whole-body exposures of low-dose gamma radiation to the entire population, essentially the same dose to risk conversion range derived by the ICRP.

Similarly, as noted above, the organization chartered by the U.S. Congress in 1964 to, among other things, "develop … recommendations about …protection against radiation" (i.e., the United States National Council on Radiation Protection and Measurements (NCRP)) uses the same dose to risk conversion factor as the 2007 ICRP.[141]

Third, the international scientific and regulatory communities have widely adopted the ICRP recommendations.[142]

ED_005285_00000744-00057

Fourth, the International Atomic Energy Agency (IAEA) (an organization in which the U.S. is a member and helped establish) and the European Union (as well as each of its member countries) utilized a 1 millisievert (1 mSv) per year acceptable level of radiation exposure, which has been widely adopted by the international community, such as the IAEA and EU regulations. This corresponds to a 26-year total dose of 26 mSv (i.e., 2,600 mrem).

The ICRP approach is more stringent than the large, and growing, body of scientific literature that radiation risks have a threshold. Also, in 2015, a U.S. Nuclear Regulatory Commission (NRC) Advisory Committee acknowledged that:

> There is a large, and growing, body of scientific literature as well as mechanistic considerations which suggest that 1) the LNT model may overstate the carcinogenic risk of radiation at diagnostic medical, occupational, and environmental doses and 2) such low doses may, in fact, exert a hormetic (i.e., a beneficial or protective) effect.[143]

The United Nations Scientific Committee on the Effects of Atomic Radiation notes that below doses of 100 to 200 mGy (roughly equivalent to 10,000 to 20,000 mrem), "[e]pidemiological studies alone are unlikely to be able to identify significant elevations in risk."[144]

Because, as a matter of policy, neither EPA nor the Nuclear Regulatory Commission has changed its "no threshold" default assumptions, this Petition does not seek to go beyond the widely accepted ICRP value. In reality, the actual risk may be lower.

E. Comparison of Radioactivity Levels from Use of PG and Naturally Occurring Background

Each exposure scenario we assessed results in a radiation dose well below the annual natural background level (see Table 1, above). The annual background level of naturally occurring radiation is 310 mrem.[145] For a 26 year period, the cumulative dose is 8,060 (310 mrem times 26), thus the total dose for a nearby resident (16 mrem) given this PG use is 0.2% of the cumulative natural background dose levels ((16 divided by 8,060) (See Section I(B) and Tables 4 and 5, above)). For the RME construction worker scenario (a risk of 0.5 in 10,000), the RME worker dose is 7% of the background dose for a worker at a road construction site not using PG. (see Tables 4 and 5, above summarizing the risks from all exposure scenarios). As a result, there

[144] UNSCEAR Report, *supra* note 142, at 8.

[145] Appendix 2.

will be no meaningful incremental increase above the background exposure dose for any of the exposure scenarios, but particularly for the nearby resident and road user.

Background levels of radiation are often considered in governmental decisions. For example, EPA's PG Workbook compares the risk from use of PG to background levels of radiation.[146] When the calculated risk for receptors in a risk assessment is lower than background, it is a relevant factor in the risk management decision.

F. EPA Policy Supports Recycling of Wastes and Waste Residuals

EPA's 1989[147] and 1992[148] risk management decisions concerning alternative uses of PG took into account the Agency's overarching policy of supporting recycling. Since 1992, EPA has increased its emphasis on adopting sustainability policies.

EPA has prioritized policies to encourage recycling of a wide variety of byproducts and other materials.[149] Similarly, the U.S. Department of Agriculture also has issued guidance on using various reclaimed materials in road construction.[150] The recycling of PG decreases raw material costs for companies and government entities that use the PG material. It also decreases greenfield impacts, increases beneficial land use, and reduces long-term maintenance costs. Reuse of PG avoids potential environmental concerns with long-term storage of PG. As EPA notes in the context of coal ash use:

> Beneficial use is the recycling or use of coal ash in lieu of disposal. For example, coal ash is an important ingredient in the manufacture of concrete and wallboard, and EPA supports the responsible use of coal ash in this manner. This final rule supports the responsible recycling of coal ash by distinguishing beneficial use from disposal.[151]

EPA recently concluded that:

---

[146] EPA PG Workbook, *supra* note 43, at 13 ("To put this number in perspective and to illustrate how little additional risk is permitted, the risk in the United States of developing a fatal cancer (from all causes) is about one in four").

[147] 1989 Rule, *supra* note 3.

[148] 1992 Rule, *supra* note 48, at 23,306.

[149] "Sustainable Materials Management (SMM) refers to the use and reuse of materials in the most productive and sustainable way across their entire life cycle. On a broader scale, SMM looks at social, environmental and economic factors to get a more holistic view of the entire system. The benefits of maximizing this connection include conserving resources, reducing waste, slowing climate change, and minimizing the environmental impacts of the materials we use." [151] EPA, Frequent Questions about Beneficial Use of Coal Combustion residuals (CCR) (last updated March 26, 2019), *available at* https://www.epa.gov/coalash/frequent-questions-about-beneficial-use-coal-ash.

> [E]nvironmental releases of COPCs from CCR fly ash concrete and FGD gypsum wallboard during use by the consumer are comparable to or lower than those from analogous non-CCR products, or are at or below relevant regulatory and health-based benchmarks for human and ecological receptors. Thus, EPA supports the continued beneficial use of coal fly ash in concrete and FGD gypsum in wallboard. Furthermore, the Agency believes that these beneficial uses provide significant environmental and economic benefits, and opportunities to advance Sustainable Materials Management (SMM).[152]

The use of CCR for beneficial use in road construction is analogous to and supports the Office of Air and Radiation's approval of the use of PG in road construction. More generally, approval of the use of PG in road construction is consistent with EPA's policy of encouraging recycling.

G. Naturally Occurring Background Radioactivity and Metals are Present Widely in the Environment, Including Existing Road Construction Materials

Many consumer products contain radioactive components (smoke detectors, clocks and watches, older camera lenses, older gas lantern mantles, older televisions and computer monitors, sun lamps and tanning salons, ceramic materials such as tiles and pottery, glassware, and some EXIT signs, among other products).[153] Most consumer products contain metals. Similarly, "[r]adioactive materials (including uranium, thorium, and radium) exist naturally in soil and rock."[154] Essentially all air contains radon and many types of soil and natural rock emit radiation.[155] In addition, virtually all road construction materials contain radioactivity and metals.

Coal ash, fly ash, bottom ash, natural gypsum, and other common construction materials[156] contain radioactive material (see Table below).[157]

A 2014 evaluation of coal ash beneficial uses concluded that:

> All of the existing evaluations identified concluded that radiation exposures from fly ash concrete are not a major source of concern. Several of these existing evaluations compared fly ash concrete to analogous products and found that the potential exposures

[157] EPA Report to Congress Re: TENORM, *supra* note 75, at Appendix A.

> do not represent an appreciable addition to the background radiation that the general public is subjected to on an annual basis. Naturally occurring radionuclides are present throughout the environment in food, air, water, soil, consumer products, and even the human body. All natural resources used in building construction (e.g., cement blocks, bricks, granite, soil, rocks) contain some trace level of naturally occurring radionuclides. For example, the USGS concluded that "the radioactivity of typical fly ash is not significantly different from that of more conventional concrete additives or other building materials such as granite and red brick." The NCRP concluded that exposures from living in concrete buildings containing fly ash are "similar to calculations made for individuals living in a brick and masonry home. Consequently, it is assumed that the use of [coal ash] in building materials has not substantially increased the average dose to an individual in the population residing in a building constructed with brick or masonry materials."[158]

The United Kingdom Health Protection Agency "concluded that exposures to '…members of the public from the use of [fly ash] in building materials is negligible.'"[159]

Thus, the appropriate risk management consideration is not whether PG has a low level of radioactivity or metals, but whether the risk is below the EPA PG risk management goal of 3 in 10,000.

H. Use of PG For Roadway Construction Provides a Net Economic Benefit and is Consistent with the Administration's Regulatory Reform Policies

A detailed report explaining the various economic benefits to be expected from approval of PG use in road construction accompanies this Petition. The report concludes that use of PG in road

construction is expected to produce cost savings ranging from $37 million to $160 million during the period 2020-2042.[160]

The approval would impose no new substantive regulatory requirements and is consistent with Presidential Executive Orders that encourage: (a) reducing unnecessarily burdensome and costly regulation;[161] (b) maximizing the use of goods, products and materials produced in the U.S.;[162] and (c) encouraging innovative strategies and trade policies.[163]

I. Other Benefits to Eliminating PG Stacks

Construction and maintenance of PG stacks are large engineering projects. There are environmental and actuarial risks presented by any such construction project. The approval of PG for use in road construction will reduce future potential risk by limiting the size of existing and potentially eliminating the need for new PG stacks.

J. Final Agency Action

EPA's determination that use of PG in road construction is deemed approved, consistent with certain criteria that must be met prior to use, constitutes final agency action under the Clean Air Act, 42 U.S.C. 7607 (b)(1), and the Administrative Procedures Act, 5 U.S.C. Section 704.

Under established legal precedents, an agency approval conditioned on specified requirements "mark[s] the consummation of the agency's decision-making process" and determines the "rights and obligations" of relevant parties, with "direct and appreciable legal consequences."[164] The approval process outlined above satisfies these legal prerequisites.

---

[160] Interestingly, the lost opportunity costs from not using fly in road construction has been estimated at $4.5 billion. Transportation Development Foundation, The Economic Impacts of Prohibiting Coal Fly Ash Use in Transportation Infrastructure Construction, 5 (Sept. 2011), *available at* https://www.artba.org/wp-content/uploads/2017/06/study2011flyash.pdf. EPA should consider this lost opportunity cost in its risk management decision.

Appendix 3 – Human Health Risk Screening for Metals and Metalloids: Phosphogypsum in Road Construction

Introduction

The Petitioners are pursuing reuse of phosphogypsum (PG) in road construction as an alternative to the current practice of stacking. As part of this request, a radiological risk assessment is required[1] and has been completed to evaluate potential public health impacts and demonstrate that the reuse is as safe as stacking. The radiological risk assessment (provided in Appendix 2) was completed with input and oversight from the U.S. Environmental Protection Agency (EPA) Office of Radiation and Indoor Air (ORIA) to evaluate radiological aspects of PG reuse, which, therefore, are not part of this chemical screening assessment. The radiological risk assessment is comprehensive, including multiple reuse scenarios.

Natural materials in PG contain low levels of radioactivity and contain various metals and metalloids. A chemical risk screening was conducted as described herein to evaluate potential risks of metals/metalloids in PG to supplement the radiological risk assessment. EPA's PG reuse guidance (ECRI 2005) requests information on "other toxic or hazardous constituents of the waste" and analyses to "assure that the proposed use does not cause non-radiological risks to human health and the environment."

The risk screening used the following four-step approach:

1. Develop an appropriately (reasonably) conservative screening scenario
2. Select health-protective and conservative screening levels
3. Screen PG data
4. Evaluate screening results.

Evaluation (step 4) included assessing PG concentrations of metals/metalloids in the context of average soil values within the United States. This risk screening employs

[1] Required to demonstrate compliance with National Emission Standards for Hazardous Air Pollutants (NESHAP); promulgated in 1989.

generic EPA screening levels based on reasonably conservative assumptions to provide a reasonable upper-bound estimate of potential risk, as an initial evaluation of the composition of the PG. The risk screening does not constitute a risk assessment and exceedances of conservative risk screening levels should not be interpreted as unacceptable risks.

An evaluation of the leaching potential of metals/metalloids in PG and a comparison to other road construction materials was completed as part of this assessment. The constructed roadway will be paved, and if PG is mixed into the cement, it will be encapsulated. Given this, potential residential exposure pathways were determined to be incomplete (i.e., no exposure) and so were not included in this risk screening. Studies indicate that for the petitioned PG reuse in road construction, leaching to groundwater (or surface water) is likely not a complete exposure pathway of concern.[2] Paving limits water contact of PG isolated within the base layer placed above the water table.

Risk Screening Scenario

A conceptual site model (CSM) was developed in the radiological risk assessment, which included five exposure scenarios. The risk assessment found that the highest incremental dose and risk identified for the exposure scenarios considered was to the road construction worker. To utilize a conservative approach in the metals screening assessment, the exposure scenario with the highest risk (i.e., the road construction worker) was selected for the risk screening scenario. The construction worker screening scenario considered exposure to PG via three routes including incidental ingestion, dermal contact, and inhalation.

The proposed PG reuse in road construction involves mixing PG with soil and compacting to create road base with placement above the water table and paving with or without PG mixed into concrete cement. There are four basic layers in roadway construction, which are, from bottom to

[2] A complete exposure pathway has four components: 1) a source and mechanism of constituent release to the environment; 2) an environmental transport medium for the released constituent; 3) a point of potential contact with the impacted medium (i.e., the exposure point), and 4) an exposure route at the exposure point. Exposure occurs when released constituents are transported to and contact a receptor. Without exposure, there is no risk.

top: embankment/foundation, subgrade, road base, and paving (i.e., concrete). These layers are illustrated in Figure 1 at the end of this memo. The specific use of PG for road construction is within the road base and/or pavement. PG is mixed in the road base (at or less than 50%) with soil or other materials such as sand and aggregates. Road base is a supporting layer of compacted material approximately 0.25 m in thickness[3] beneath the pavement and above the subgrade. It serves to provide resiliency to the road. PG may also be used in a smaller fraction (approximately 2.25%) in the paving. The surface paving serves to isolate the compacted base layer from the environment. This eliminates direct contact with the road base material once the road is paved and limits water contact of PG within the base layer.

Leaching to groundwater (or surface water) is likely not a complete exposure pathway for the petitioned PG reuse in road construction. This is because roadways are sloped to drain precipitation and paving will act as a barrier to infiltration through the compacted road base beneath. Despite this, literature regarding leaching and water quality was evaluated as part of this screening assessment (see the section titled "Leaching and Water Quality").

PG Composition Dataset

A comprehensive literature review was conducted to develop an understanding of the non-radiological composition of PG. PG concentration data were assembled from four domestic and one international study; concentrations from these studies are compiled in Table 1 at the end of this memo.

Florida

The U.S. Bureau of Mines studies published by May and Sweeney in 1984 were conducted to characterize PG under "a variety of conditions encountered in either processing or storage" (May and Sweeney 1984a,b). Nine stockpiles (i.e., stacks) were sampled in Florida from PG generated by two different manufacturing processes; six stacks were active and three were inactive. This published dataset provides average concentrations of trace metals measured in the stacks.

[3] This thickness was selected for the risk analysis.

Calculated average concentrations for at least one part of the study (May and Sweeney 1984a) excluded non-detects, which results in averages that are biased high.

The Mostary (2011) study from University of Florida characterized PG from a stack in Mulberry, Florida. The published dataset provides multiple analyses, including total metals results for samples collected from the top of one stack at four walls.

Idaho

The Luther et al. (1993) study at University of Alberta characterized PG from a decommissioned plant in Southern Alberta that used beneficiated ore from southeastern Idaho. The published dataset presents maximum concentrations of trace metals measured in PG originating from Idaho phosphate rock.

Louisiana

The Taha et al. (1992) South Dakota State University and Louisiana State University study was a joint research program for evaluating PG use as a road base and included two engineering companies. The published dataset is a range of trace metals concentrations measured in Louisiana PG.

International

International PG data were collected and published by the International Atomic Energy Agency (IAEA) in 2013 (IAEA 2013). The IAEA published a dataset of reported minimum and maximum concentrations of trace metals in PG generated in the United States and worldwide.

EPA Screening Levels

The road construction worker scenario was evaluated for incidental ingestion, dermal contact and dust inhalation of PG using EPA's generic Regional Screening Levels (RSLs)[4] published for "composite worker" exposure to soil, which is defined by EPA as follows:

> *This is a long-term receptor exposed during the work day who is a full-time employee working on-site and spends most of the workday conducting maintenance activities outdoors. The activities for this receptor (e.g., moderate digging, landscaping) typically involve on-site exposure to surface soils. The composite worker is expected to have an elevated soil ingestion rate (100 mg per day) and is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal contact with soil, inhalation of volatiles and fugitive dust. The composite worker combines the most protective exposure assumptions of the outdoor and indoor workers. The only difference between the outdoor worker and the composite worker is that the composite worker uses the more protective exposure frequency of 250 days/year from the indoor worker scenario* (U.S. EPA 2019).

EPA's generic composite worker RSLs based on either a hazard quotient of 1 for non-cancer effects or a lifetime cancer risk of 1×10^{-6} to address cancer were used as a starting point to perform the human health screening assessment. Non-cancer-based screening levels were used as published by EPA. A simple adjustment was made to the carcinogenic screening levels. The cancer-based RSLs were adjusted from a lifetime cancer risk of 1×10^{-6} to 1×10^{-4} to be in the same range as EPA's cancer risk management level for PG use while maintaining the conservative nature of the exposure assumptions used to develop the screening levels. The lowest RSL (i.e., cancer or non-cancer-based) was selected for metals with cancer and non-cancer effects. The exposure parameter assumptions used by EPA to develop the generic composite worker RSLs are conservative.

---

[4] https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables

All road construction materials, including PG, have varying chemical compositions and are used routinely by construction workers. Exposures may be absent or minimized through normal controls and best management practices (BMPs) such as wetting the construction area to prevent dust formation.

Average Soil Concentrations

The highest concentration of each element found in PG from the literature review was compared against the average surface soil (0–5 cm) concentration in the coterminous United States published by the U.S. Geological Service (USGS; Smith et al. 2013). This methodology is a very conservative screening approach since it compares maximum PG values to average soil values. For the elements boron, neodymium, ytterbium, and zirconium, where no data were available from Smith et al. (2013), average surface soil (up to 20 cm in depth) concentrations were taken from a previous USGS dataset (Shacklette and Boerngen 1984). For some rare earth elements (dysprosium, erbium, europium, gadolinium, lutetium, and samarium) without reported values in either Smith et al. (2013) or Shacklette and Boerngen (1984), the highest average concentration was gathered from a review by Tyler (2004). These average United States soil concentrations are summarized in Table 1. The chemical composition of PG is directly related to the mined phosphate ore used to manufacture phosphoric acid. Therefore, the concentration of many of the metals and metalloids in PG are similar to or below these average United States levels (e.g., aluminum, barium, iron, potassium, magnesium, manganese, lead, zirconium, and others), while some of these background constituents are concentrated in the manufacturing process and are higher in concentration in the PG.

Risk Screening

The highest published metals concentrations in PG for the United States and international studies discussed above were screened against the EPA RSLs for a composite worker. Only two metals, lanthanum (La) and zirconium (Zr), exceeded their risk-based composite worker RSLs in PG from some but not all sources in the literature reviewed. To put these maximum concentrations in perspective, both metals were then screened against average concentrations of these analytes in

ED_005285_00000745-00007

surface soils data published by the USGS (Shacklette and Boerngen 1984). Of these two metals, only La exceeded the USGS average concentration in soil.[5] However, PG will be mixed with other road construction materials. As much as 50% PG will be used in road base, and approximately 2.25% will be used in paving.[6] For these mixtures, the maximum La concentrations in PG used in road base and paving are expected to be less than the conservative EPA composite worker RSLs.

Zr is the twentieth most common element in the Earth's crust (Haxel et al. 2002) and resembles titanium in its physical and chemical properties (Shahid et al. 2013). Across the conterminous United States, Zr is found at an average concentration of 180 mg/kg in surface soils (Shacklette and Boerngen 1984), which is greater than the maximum PG concentration reported in the literature reviewed. More than 140 recognized mineral species contain Zr, but zircon and baddeleyite are the main naturally occurring compounds in soil. Zr is generally regarded as immobile in soil due its low water solubility and ability to form strong complexes with many different soil components (Shahid et al. 2013).

La is one of 15 elements commonly known as rare earth elements, and it belongs to a group of elements known as "lanthanides." It occurs naturally in the earth's crust at a concentration of approximately 39 mg/kg (Tyler 2004) and in surface soils in the United States at a concentration of 26 mg/kg (Smith et al. 2013). Among the rare earth group, La is the most electropositive element and occurs uniformly as a trivalent cation (La^{3+}) in a variety of carbonates, oxides, phosphates, and silicates (Gambogi 2013). La occurs naturally in phosphate rocks (such as the source rock for fertilizer production) through binding with PO_4^{3-} anions to form the mineral rhabdophane. In general, lanthanide salts of chloride, nitrate, and perchlorate are soluble, while the hydroxide, carbonate, phosphate, and fluoride salts are insoluble (U.S. EPA 2018). The solubility of La increases under acidic conditions (Larrañaga et al. 2016). La is added to sensitive

---

[5] The RSL for La was based on data from the provisional peer-reviewed threshold values (PPRTV) for soluble La; insoluble salts are expected to have considerably different toxicokinetic characteristics. It is expected that only a small portion of the PG would become soluble under environmental conditions. This makes the comparison between maximum La concentrations in PG and the RSL overly conservative due to the limited La solubility.

[6] Cement would include 15% PG, but when it is mixed to generate the concrete paving the overall proportion of PG in the mixture is reduced to about 2.25%.

surface water bodies, including lakes, as the active component in Phoslock, which is used to remove phosphate. Use of La-containing Phoslock in these sensitive areas has been studied and determined to be of "low toxicity and safe to use in all naturally-occurring environmental conditions at the recommended dosages."[7] Therefore, although La occurs naturally in phosphate rocks, and, therefore, in PG, it is handled routinely in certain products, including application by workers in sensitive areas such as lakes.

Comparison to Other Road Construction Materials

All road construction materials have some level of naturally occurring radioactive materials and metals/metalloids. This includes soils, rock, Portland cement, and reused waste materials such as fly ash. As an example, Table 2 summarizes the maximum concentrations reported in literature for PG assembled for the risk screening compared with reported median concentrations in fly ash and Portland cement. As shown in Table 2, a more comprehensive PG dataset was developed for this Petition compared with fly ash and Portland cement datasets reported to EPA to demonstrate the safety of fly ash reuse in concrete and wallboard in 2014 (U.S. EPA 2014).

Of the metals/metalloids reported in fly ash, approximately half of the median concentrations are higher than the maximum concentrations reported for PG. Aluminum and iron concentrations are approximately 16 times higher in fly ash than in PG, and other constituents such as arsenic, chromium, and manganese are slightly higher in fly ash. Boron, barium, beryllium, lead, and vanadium are between approximately 3 to 7 times higher in fly ash compared with PG. EPA has approved the beneficial reuse of fly ash, and its use as a road construction material is excluded from federal regulation. State agencies have primary responsibility for regulating beneficial reuses. Although concentrations of many metals/metalloids are lower in PG than in fly ash, the petitioned reuse of PG in road construction involves applications above the water table in a compact and/or encapsulated form (i.e., in road base and/or paving).

Leaching and Water Quality

In any situation with metals in soils or sediments, leaching is largely governed by pH and environmental conditions. Metals may leach from PG under certain conditions (e.g., laboratory testing; Taha et al. 1992). Some investigators have studied the leachability of PG. For the most part, these studies show limited leaching. This includes a recent University of Florida study by Mostary (2011) with comprehensive leachability testing for PG sampled from one stack in Florida. In this study, there were no exceedances of EPA's primary drinking water standards in synthetic precipitation leaching procedure (SPLP) testing and no exceedances of Resource Conservation and Recovery Act (RCRA) toxicity characteristic leaching procedure (TCLP) limits.

Leaching is not expected to be a complete pathway of concern for the petitioned use of PG in road construction. The specific use of PG for road construction is as road base when mixed (e.g., at or less than 50%) with other materials such as soil, sand, or aggregate. As shown in Figure 1, road base is a supporting layer of material ~0.25 m in thickness beneath the pavement and above underlying soil and fill. It serves to provide resiliency to the road. PG may also be used in a smaller fraction (~2.25%) as part of the surface pavement. The design of new roads as depicted in Figure 1 affects potential for exposures by creating a degree of isolation of the base layer from the environment. This limits direct contact by the community and limits water contact of PG isolated within the base layer.

The wide-scale use and attention paid to the risks of biosolids for land application provides a point of comparison for the risks of metals in PG and associated leaching. The use of biosolids for land application is regulated under the EPA Part 503 Rule,[8] which has been adopted by states (e.g., Florida Chapter 62-640, F.A.C.). Florida had 95 permitted biosolids application sites in 2016 (FDEP 2016). The guidelines establish application limits for nine metals:[9] arsenic, cadmium, copper, lead, mercury, molybdenum, nickel, selenium, and zinc. EPA selected these

[8] See U.S. EPA 1995 for a guide on the Part 503 Rule.

[9] EPA has amended Part 503 periodically since initial publication, including deletion of numerical standards for chromium to be land-applied (60 FR 5464, October 25, 1995).

metals for risk assessment based on an initial risk screening of all the metals that may be present. EPA then evaluated risks to human health for 14 exposure pathways (Table 6 in U.S. EPA 1995). They identified the limiting pathways (i.e., the pathway resulting in the highest exposure risk; Table 11 in U.S. EPA 1995) and associated allowable metals loadings and concentrations in biosolids (Tables 10 and 16, respectively, in U.S. EPA 1995) for continual land application. Limiting pathways determined by EPA involved direct contact or uptake in plants that are subsequently ingested as would be the case for subsistence farmers. For metals in biosolids, EPA found that leaching into groundwater or runoff into surface waters were not limiting pathways.

As described in the metals screening assessment, direct contact exposure for workers applying PG in road construction is within acceptable risk limits. With the exception of two individual cadmium values reported for international studies, the maximum metals levels in PG in mixtures for road construction are also below those set forth by EPA for biosolid application to be safe for direct contact and plant ingestion by the public. These are not complete pathways for roads, inasmuch as the PG is embedded within the road, preventing direct contact and plant ingestion by the public.

It is important to consider that EPA deemed very high allowable metals (biosolids) loadings (many with unlimited risk-based pollutant loadings) to be safe for continuous application on fields that are watered, infiltrating precipitation through the soil column, and moving into surface and ground waters. Moreover, the footprint of a road on the landscape is very small compared to agricultural lands upon which biosolids and amendments with many higher allowable metal concentrations than those in PG are permitted for continuous use. The smaller footprint and lower likelihood of leaching from a constructed road compared to an agricultural field indicates that the influence on groundwater from PG in the road is likely to be comparatively very small. PG in road base is expected to be negligible in comparison and thus can be used safely in road construction given the lower metals content in PG and the smaller footprint and confinement of the base layer above the water table.

State and Federal Road Construction Requirements

The relevant department of transportation has responsibility to ensure that a state- or federal-funded new road project can be constructed and used in a manner that is judged adequately protective of the environment. State law primarily governs groundwater and surface water protection. Road construction projects also rely on local, state, and federal environmental guidance pertaining to water quality protection.

Agencies promote sustainability and use of recycled materials in road construction. The fact that road construction materials can impact the environment has been reported by the National Academy of Science (NAS; CEIRD 2005), states (Idaho; Casey et al. 2014), and other federal agencies (U.S. Department of Agriculture; Melton and Kestler 2013). This applies to all road construction material, not just PG. States provide comprehensive design of roadways with assessment of potential impacts during and after construction and mitigating measures if warranted, regardless of the source of construction materials. The following manuals and guidance documents illustrate agency considerations in the roadway design process.

U.S. Department of Transportation, Federal Highway Administration

The U.S. Department of Transportation, Federal Highway Administration (FHWA) released guidelines for use of coal fly ash and other materials (e.g., kiln dusts) in asphalt concrete, Portland cement concrete, stabilized base, flowable fill, and embankment or fill (FHWA 2016). When the guidelines were first published in 1997, fly ash had been "successfully used as a mineral admixture in PCC for 60 years," "as a substitute mineral filler in asphalt paving mixtures for many years," and "for several decades as an embankment or structural fill material."

FHWA also issued fly ash guidance documentation specifically for highway engineers (ACAA 2003). This included discussion of design issues and consideration of potential environmental impacts.

- "Design issues. The mechanical behavior and compaction characteristics of fly ash are generally similar to those of silt. For this reason, fly ash also shares

ED_005285_00000745-00012

some of the difficulties that are characteristic of silt such as dusting, erosion and frost susceptibility. These difficulties can be properly addressed during the design of the embankment."

- "Environmental impacts. The trace element concentrations in many fly ashes are similar to those found in naturally occurring soils. Although the leachates of some fly ashes may contain trace element concentrations that exceed drinking water quality standards, this is also true of certain soils. State environmental regulatory agencies can guide you through applicable test procedures and water quality standards. The amount of leachate produced can be controlled by assuring adequate compaction, grading to promote surface runoff, and daily proof-rolling of the finished subgrade to impede infiltration. When construction is finished, a properly seeded soil cover will reduce infiltration. For highway embankments, the pavement may be an effective barrier to infiltration.

California Department of Transportation

The California Department of Transportation (Caltrans) Highway Design Manual (Caltrans 2018) includes discussions on controlling water pollution, testing, and availability of road construction materials and encourages use of recycled materials.

- "Control of Water Pollution. Water pollution related to the construction of highways and to the drainage of completed highways should be limited to the maximum extent practicable. This objective should be considered from the early planning, through the detailed design phase, to the end of construction of each project."
- "Materials and Geotechnical Services. The Materials unit is responsible for conducting laboratory testing, field testing, specialized field inspections, and maintaining the test method procedures for the Department. The GS [Geotechnical Services] unit provides the Districts, Structures, and

Headquarters with expertise and guidance in soil related investigations and groundwater issues"

- "Availability of Materials. The availability of suitable materials such as subbase and base materials, aggregates, binders, and cements for pavements should be considered in the selection of pavement type. The availability of commercially produced mixes and the equipment capabilities of area contractors may also influence the selection of pavement type, particularly on small widening, reconstruction or rehabilitation projects. Suitable materials that are locally available or require less energy to produce and transport to the project site should be used whenever possible."
- "Recycling. The Department encourages and seeks opportunities to utilize recycled materials in construction projects whenever such materials meet the minimum engineering standards and are economically viable. Accordingly, consideration should be given on every project to use materials recycled from existing pavements as well as other recycled materials such as scrap tires. Existing pavements can be recycled for use as subbase and base materials to be surfaced with a flexible structural surface course, or as a partial substitute for aggregate in hot mix asphalt mixes. The decision to use recycled materials should be made based on a thorough evaluation of material properties, performance experience, benefit/cost analysis, and engineering judgment."

Florida Department of Transportation

The Florida Department of Transportation (FDOT) Manual of Uniform Minimum Standards for Design, Construction and Maintenance for Streets and Highways (the Florida Greenbook; FDOT 2018). Chapter 1 of the manual includes a section (C.8) for environmental impact planning to mitigate adverse impacts in the project planning stage.

Illinois Department of Transportation

The Illinois Department of Transportation's (IDOT's) Bureau of Local Roads and Streets Manual (IDOT 2018) includes discussion of considering potential groundwater impacts from highway projects. "In the development of proposed LPA [Local Public Agency] highway projects, potential impacts to groundwater resources consideration should be given to implementing practical measures for avoiding, minimizing, and mitigating adverse project impacts to those resources, see Section 26-22 of the BDE [Bureau of Design and Environment] Manual."

Washington State Department of Transportation

The Washington State Department of Transportation (WSDOT) Use of Recycled Materials in Highway Construction document (WSDOT 1992) detailed findings of a research study on the use of recycled materials in highway construction directed by Senate Bill 5143 that investigated tires, glass, asphalt concrete, fly ash, compost, mixed plastics, and aluminum sign stock. The document discusses strategies to test and monitor use of recycled materials in road construction, product specifications, programs to demonstrate feasibility, and identification of recycled material sources and vendors. It includes evaluation with the Washington State Department of Ecology as needed and highlights "large amounts of fly ash" used in WSDOT's reconstruction of the Lacey V. Murrow Floating Bridge (i.e., concrete floating bridge crossing Lake Washington in Seattle completed in 1993) (Lwin et al. 1995).

Roadway design is comprehensive; agencies governing road construction assess construction materials, potential impacts, and if necessary, mitigating measures. Thus, all construction materials, including but not limited to PG, are addressed by the highway construction process. This decision-making is in the purview of the agencies that govern road construction.

Conclusions

A conservative human health risk screening was conducted as a first step to determine whether further risk evaluation is warranted to assess construction worker exposure to metals in PG used

for road construction. The conservative risk screening demonstrates that metals levels in PG are not expected to pose an unacceptable level of health risks to construction workers using PG in roadway construction. Furthermore, proper construction practices employ BMPs such as wetting surfaces to reduce dust formation, and these measures serve to further lower exposure. Studies and the nature of the petitioned PG reuse in road construction material compacted and/or encapsulated below pavement and above the water indicate that leaching to groundwater (or surface water) is likely not a complete exposure pathway. The relevant department of transportation has responsibility to ensure that construction, using materials including PG, is conducted in a manner that is judged adequately protective of the environment.

Limitations

This document summarizes work performed to date and presents the findings resulting from this work. The findings presented herein are made to a reasonable degree of engineering and scientific certainty. Exponent reserves the right to update this document as more information becomes available.

Subject:
Response to EPA Questions issued on Jan 16, 2020

In response to a set of questions from the United States Environmental Protection Agency (USEPA), related to the risk assessment report submitted in October 2019[1] as support to the petition for beneficial use of phosphogypsum, Arcadis has prepared the following responses and comments.

For each paragraph provided by EPA in their questions, Arcadis has provided a response. Where a full response could not be included in this memo, reference to additional information is provided.

Modeling approach:

1. USEPA: The developers of the risk assessment chose to use a deterministic (vs. stochastic) model using discrete input parameters judged to be typical. From the standpoint of model development, this was a simpler—and potentially clearer—approach. However, a probabilistic approach to model input parameters could have provided the opportunity to incorporate uncertainty and variability into the model, and also could have explicitly included other road designs or variations on road design.

Arcadis: Arcadis intentionally chose a deterministic approach as a full probabilistic approach is quite challenging to present to the public. We recognize that there are variations in scenarios and assumptions and therefore, we intentionally made assumptions and selected parameters that in our view overestimate the potential exposures and doses bracketing the risk. Moreover, the models are linear for key parameters, such as Ra-226 concentration and exposure duration and hence readily scalable. In addition, we believe that the current approach estimates a reasonable maximum exposure (RME).

The RME scenario considers the highest exposure that might reasonably be expected to occur, one that is well above the average case of exposure but within the range of possibility and is intended to provide the basis for estimating the maximum individual risk (MIR). Use of the RME to model baseline human health risks is a conservative approach, in that it yields upper-bound cancer risk and non-cancer hazard estimates (USEPA, 1989). The "intent of the RME is to estimate a conservative exposure case (i.e., well

---

[1] Arcadis 2019. *Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum*, Report to The Fertilizer Institute, October.

above the average case) that is still within the range of possible exposures."[2] Each exposure factor used to estimate the RME should be selected "so that the resulting estimate of exposure is consistent with the higher end of the range of plausible exposures" (citing EPA 1991 guidance).[3]

A National Academy of Science (NAS) Committee reviewing EPA's regulation of technologically enhanced naturally occurring radioactive material (TENORM) recommended that EPA "should use exposure and dose risk assessments that are "reasonably realistic"" in developing standards for exposure to the various types of low level naturally occurring radiation.[4] "The Committee defined "reasonably realistic" as "not … .intended to greatly overestimate or underestimate actual effects for the exposure situation of concern."" and EPA agreed with the Committee's recommendations.[5] The use of reasonable exposure assumptions is supported by the courts, which have long held that exposure assumptions used "must bear some rational relationship" to the actual conditions, and disallowed unduly conservative approaches.[6]

The current deterministic approach of the Risk Assessment focusing on RME scenarios to estimate MIR, provides the best alignment with the purpose of the RA, to compare predicted risks from the proposed use of PG against the risk threshold that is consistent with the determination of a 'safe' level. Overall, the choice of parameters other than those used in the current risk assessment are more likely than not to result in lower doses and risks to the receptor.

Probabilistic (stochastic) approaches would provide added information of the potential variability and uncertainty of the risk at lower risk levels, but overall would not change MIR substantially. In addition, the

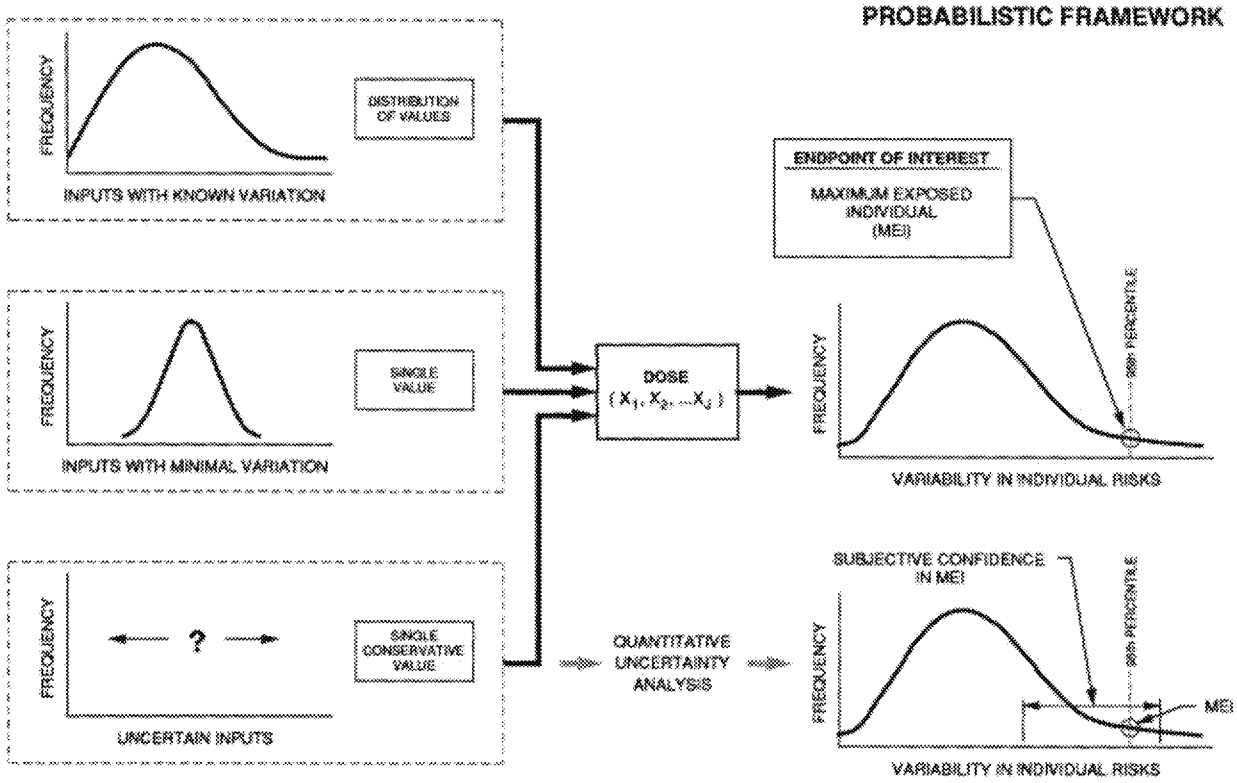
complexity of developing subjective probability distribution functions for the model parameters can be quite difficult and often challenging to explain to the general public and thus the probabilistic approach was not selected for the assessment. The modelling approach using deterministic parameters to calculate RME dose and risk estimates was reviewed with EPA in advance of the Risk Assessment.

To illustrate the possible output of a probabilistic approach Figure 1.1 is provided below. The deterministic approach targets calculations for the Maximum Exposed Individual (MEI) or person in the RME scenario, often someone at the upper-end (approximately 90th to 95th percentile) of dose (risk). EPA guidelines state that the assessor may derive a high-end estimate of exposure by using maximum or near maximum values for one or more sensitive exposure factors, leaving others at their mean value.[7] Based on our experience with regulatory decisions, the MIR from a deterministic assessment as performed in our October 2019 risk assessment would be generally comparable to these upper limits of dose (risk).

FIGURE 1.1

PROBABILISTIC FRAMEWORK



[7] Exposure Factors Handbook: 2011 Edition at (2011) https://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252.

2. USEPA: 61.206(b)(8) requires the risk assessment to include an estimate of the risk distribution.

Arcadis: The original NESHAPS (December 15, 1989 Federal Register) defines a risk distribution estimate as how many persons within a certain distance (e.g. 80 km) of a source of pollutant emissions are at an increased level of individual risk. This requires an estimate of the dispersion of a radioactive pollutant, from a source and an estimate of the population within that distance.

EPA clarified at our meeting that providing more risk distribution information was information on how the risk varied with the "variation of the geometry of exposure" and with different exposure time frames. The RME approach utilized in the risk assessment also serves as a reasonable upper bound on the risk distribution and is a readily accepted approach for not only representing the maximum exposures but also providing insight into risks to people who might be exposed to PG. RMEs are constructed to likely overestimate risks for highest exposure situations; actual risks to these people and risks to the rest of the population would all be lower. Knowledge is relied upon for setting such bounds for the RME and when bounded values are used in calculation, the results are conservative (i.e., higher) estimates of the risks.

Although risk distribution was used in 1989, many EPA risk assessments (including the 1992 BID risk assessment) do not utilize risk distribution. The general risk distribution discussed below is acceptable in this situation.

The radiological "pollutants" associated with PG in roads are direct gamma emissions, particulates, and radon. As shown in the risk assessment, external gamma is by far the dominant source of dose, followed by radioactive particulate emissions and radon.

The gamma exposure dose decreases rapidly with distance, for example at one road used in a Florida Institute of Phosphate Research (FIPR) study, the exposure was indistinguishable from background levels at 50 feet from the road centerline (FIPR, 1989[8]). For the nearby residential exposure scenario, the risk calculated in the October 2019 radiological risk assessment calculated that radiological exposure is always below background levels and reduces with distance from the road, becoming indistinguishable from the variability of background at 50 feet from the road's edge.

Background terrestrial radiation has been shown to have wide variability between states and within states in the US (S. Cohen & Associates 2005)[9].

> *It is instructive to note that not only are there substantially large differences in the average terrestrial doses among states (e.g., 14.3 mrem/yr in Florida versus 42.6 in Colorado), but there are also large differences in the average terrestrial dose rates among cities within a state. For example, in Colorado, the average terrestrial dose rate in Pueblo is 29.2 mrem/yr, while in Denver it is 57.4 mrem/yr. In Las Vegas, Nevada, the terrestrial dose rate is 12.7 mrem/yr, while in non-urban regions of Nevada it is 29.2 mrem/yr.*

[8] Chang, Wen F., Chin, David A., and Ho, Robert, 1989. Phosphogypsum For Secondary Road Construction, University of Miami, For Florida Institute of Phosphate Research, Publication No. 01-033-077, 01-041-077.

[9] S. Cohen & Associates. 2005. Assessment of Variations in Radiation Exposure in the United States Contract Number EP-D-05-002 Work Assignment No. 1-03. Prepared for U.S. Environmental Protection Agency Office of Radiation and Indoor Air 1310 L Street, N.W. Washington, DC 20005.

The USNRP in Report No. 160[10] confirms the range of background terrestrial radiation dose in the USA is variable, depending on local geology and other factors, and ranges from about 10 mrem/y to more than about 40 mrem/y.

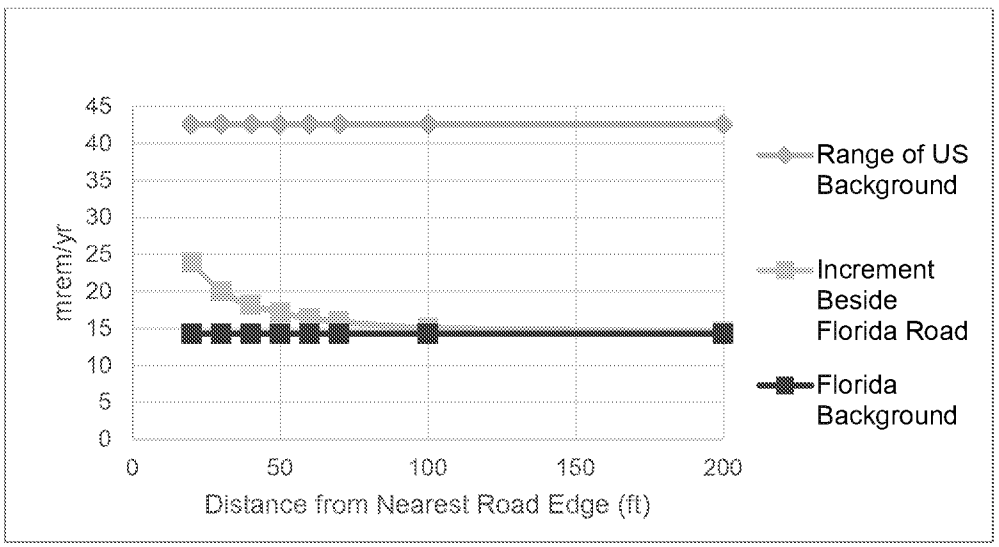
Figure 2 below combines the (notional) background radiation dose in Florida with the incremental dose from a PG road. The figure also displays the upper range of background radiation dose in the US (for Colorado). This clearly shows that dose from a PG road is inconsequential relative to background for distances typical for the closest residence. Further it shows that at distances reasonable for a second closest residence (approximately 100 feet) the dose is essentially zero.

These distances are well short of the 80 km values used in the 1989 risk distribution. Therefore, the contribution to a risk distribution is zero beyond that distance.

Similarly, it was shown in the Risk Assessment that the dose from inhalation and ingestion of particulates was also quite low, less than 10% of the total dose for the worker in the center of the road. As particulate concentration is highest on the road in the construction zone, particulate concentrations reduce with distance from the road and will quickly reach background levels again resulting in zero dose contribution to the risk distribution. In addition, particulate generation is only relevant during construction which occurs for a limited duration in any one location.

Last, is the radon generated from the road. Outdoor radon is quickly disbursed to background levels within a few tens of feet from the road, see for example the measurements on roads constructed with PG. (FIPR, 1989, "Phosphogypsum for Secondary Road Construction"). As previous, the calculated contribution to the risk distribution from radon is zero.

Figure 1 – Incremental External Gamma Dose with Distance Compared to Terrestrial Background



[10] NCRP Report No. 160, Ionizing Radiation Exposure of the Population of the United States

The following table provides summary comments on risk distributions by exposure pathway. The table explains the limited applicability of the RME scenario and the potential for lower exposures and doses to occur for a broader population.

SUMMARY OF RISK DISTRIBUTION FROM USE OF PG IN ROAD CONSTRUCTION		
Exposure Scenarios	RME (small number of people)	Potential Lower Exposures and Risk Distribution
Road Construction Worker	Risk: 0.5 in 10,000 Few if any workers would fit the RME assumption of 100% of workdays on the uncovered road base. The RME worker is exposed to less than 7% of background levels (for all members of the public.	Much less than 0.5 in 10,000 Most workers are expected to spend less than 100% of the workday on the uncovered road base. Dose and risk reduce linearly with reduced exposure time. Time on a covered road base was shown in the Risk Assessment to be a factor of 5 lower. The dose would range down to essentially zero for management and supervision who would spend very limited time on the road and out of vehicles. The number of workers in a road crew is estimated to be as small as 6 – 8 workers, which limits the risk distribution to a small group.
Road User	Risk: 0.1 in 10,000 This RME is assumed to be a heavy user of the road spending 2 hours daily on the road. This scenario is unlikely to occur until far into the future if PG roads become widely available. Until then it is unlikely a commuter would be able to spend this amount of time on a PG road. In the extreme case, the RME road user is exposed to less than 0.3% of background.	Well below 0.1 in 10,000 Most road users will be on the road for much less than two hours per day. Dose and risk reduce linearly with reduced exposure time. Initially when PG use in roads is newly implemented the availability of PG roads will be low reducing the opportunity to have substantive usage time. As the total amount of PG roads increase the risk distribution would increase with additional road users and cumulative usage time. The overall risk to an individual however, is not expected to exceed the RME estimates. Most road users would still have limited time on PG roads and this results in a proportionally limited dose and risk. The overall number of road users is difficult to specify as it depends on several factors including

		the road type and location relative to populated areas. However, the dose to road users would remain a small fraction of that from unavoidable background radiation.
Truck Driver	Risk: 0.5 in 10,000 The Truck Driver RME is limited to workers who participate in PG road construction projects. The assumptions for this scenario are set to estimate the upper end of likely dose and risk for this work. The RME Truck Driver is exposed to less than 6% of background levels.	A truck driver that has less than an RME exposure has lower risk than 0.5 in 10,000. There are a limited number of truck drivers involved in a road construction project. In addition, truck drivers will support numerous construction projects during the course of a year and many not involving use of PG. This limits the risk distribution for this exposure pathway to a relatively small number of people. In many cases, Truck Drivers will not work on PG road construction as much as assumed for the RME, resulting in a lower dose and risk.
Nearby Resident	Risk: 0.08 in 10,000 The Nearby Resident RME is based on extreme assumptions that are unlikely to apply to all residents of a PG road. The assumptions include close exposure to the road and long durations of residency throughout the exposure period. Based on these assumptions the Nearby Resident RME is exposed to 0.2% of background levels.	Most residents near a PG road would be exposed to much lower doses and risk, well below 0.08 in 10,000. Radiation levels from a PG road decrease rapidly with distance from the road and become indistinguishable from background at 50' to 100'. See figure and discussion. As a result, most residents immediately beside a PG road would be exposed to much less than the RME risk level, and residents beyond the immediately adjacent properties would experience essentially zero incremental risk. The overall risk distribution would depend on the overall length of the PG road and population density along the road but is limited to only those locations immediately beside the PG road.
Utility Worker	Risk: 0.004 in 10,000 The Utility Worker RME scenario represents an extreme case where a worker needs to disrupt the road for road or utility maintenance. The assumptions use worst case conditions to estimate the risks	Most Utility Workers would be exposed to risk much less than 0.004 in 10,000. Most utility repair requirements would involve exposure scenarios below those assumed for the RME conditions, due to smaller trenches and exposure areas, or shorter durations.

	and are limited to workers in a trench in a PG road and meeting the other exposure assumptions. The RME Utility Worker is exposed to approximately 0.3% of background levels.	The number of individuals entering a trench in a PG road is also limited based on the uniqueness of the work and the limited space. As a result, the risk distribution for the Utility Worker is limited to a small number of individuals.
Reclaimer Extreme Scenario	Reclaimer is an extreme scenario well beyond an RME assumption and therefore, is not appropriate to determine whether the use of PG is safe. This example for ultimate disposal was selected due to the use by EPA in 1992. Risk: 0.4 in 10,000 The Reclaimer would be exposed to approximately 1% of background levels. (total exposure of 78 mrem compared to a Background of 8,060 mrem over 26 years)	The Reclaimer scenario represents an extreme situation that is unlikely to even occur as described. As a result, the risk distribution is effectively zero. More realistic situations for the ultimate disposal of the road include continued use of the road as a road, or reuse of the PG road base for a new road, if the road was to be relocated or realigned. In the extreme case where a road is abandoned and then the land is reused for other purposes, the land preparation activities will realistically result in blending and mixing of the road base to levels that are indistinguishable from background levels. Overall, the risk distribution would be effectively zero.

In summary, the risk distribution from road construction is negligible, beyond the individuals who are on or immediately beside the road, as assessed in the Risk Assessment document.

3. USEPA: No discussion of uncertainty in model outputs is provided. There is no discussion of uncertainty around model input parameters, with the minor exception of uncertainty of the dose-to-risk conversion factor (p. 1-1). Except for briefly mentioning variability in naturally-occurring background radiation (p. 3-4), the risk assessment does not address variability around model parameters such as exposure factors, activity concentrations, exposure duration, etc.

Arcadis: The Risk Assessment was developed to examine a conceptual road design, to provide an estimate of the upper end RME risks associated with PG use in roads. It is impractical to perform a risk assessment that uses different values for every conceivable road design. Neither the 1989 nor the 1992 BID risk assessment considered every conceivable road design. Many features (such as the number lanes) do not affect the potential exposure. Many other road design features were set at an upper bound RME value and any design that uses different value will reduce the risk or not be an RME.

The following is an example list of factors utilized to minimize the impact of any uncertainties.

- We assumed that EPA's 1992 BID risk assessment used high end assumptions as was the policy at the time. In general, the 2019 radiological risk assessment is more conservative (i.e., results

in higher exposures) than the 1992 BID. The 2019 radiological risk assessment used the same exposure scenarios plus two new exposure scenarios.

- In conjunction with the submission of the Petition, TFI members agreed to perform radiological testing of PG. Nine PG stacks located in Central Florida (where the highest Ra-226 levels would be expected), Louisiana, and the Western U.S. with ten samples taken from each stack, for a total of 90 samples.4 A summary of the results is as follows:
    - The average Ra-226 concentration of all 90 samples is 18.6 pCi/g.
    - Ra-226 concentrations in individual samples range from 6.3 pCi/g to 27.9 pCi/g.
    - The average Ra-226 concentration from the 2019 stack sampling (18.6 pCi/g) is below the radioactivity concentration limit of 35 pCi/g proposed in the Petition, and well below the average Ra-226 concentration of 148 pCi/g that corresponds to an EPA safe risk level of 3 in 10,000.
    - No individual concentration from the 2019 stack sampling (with concentrations ranging from 6.32 pCi/g to 27.9 pCi/g) exceeds 35 pCi/g.
- The EPA 1992 BID assumed a 1:2 dilution of PG with soils for a road base concentration of 10 pCi/g. The October 2019 risk assessment utilized less dilution (1:1 PG:soil).
- The EPA 1992 BID assumed the road base was 0.25 m thick and 30 feet (9.15m) wide and that the road base is covered with a 0.12 m (5 in) thickness of asphalt. The October 2019 risk assessment utilized a road thickness of 0.25 m (the same as in 1992).
- The EPA 1992 BID assumed PG in a concrete road incorporates 15% PG by weight and 0.12 m thick (5 in) and 24 feet wide (7.32 m). The October 2019 reviewed road base design criteria and concluded 15% was a high-end criterion.
- The EPA 1992 BID used exposure to the critical population group member (nearby resident 100 m (i.e., 328 ft) from the edge of the road). The October 2019 radiological risk assessment calculates the radiation levels at 50 feet from the edge of the road.
- The current risk assessment assumes a worker moves around over the road surface and is exposed at the average of the gamma fields at the center and edge of the road, which is more reasonable than assuming a worker never moves for 5 years. The stationary worker is not realistic or reasonable, therefore it is not an RME.
- The 1992 EPA risk assessment used a 0.6 shielding for the road user, but rather than determine the degree to which vehicles have changed the amount of metal in the under carriage of cars, the current risk assessment takes no credit for shielding provided by the vehicle which however would provide some level of shielding which is a conservative assumption and could reasonably be considered.
- The current risk assessment considered two receptors beyond those considered in the 1992 BID (truck driver and utility worker).

Given the fact that each of the exposure assumptions are RME (including road design parameters), the uncertainty is addressed with the risk assessment without having to perform numerous risk calculations that will simply confirm the nature of the RMEs utilized. If EPA identifies any road design factors that increase the radiological risk and are RME, the Petitioners will evaluate it. In summary, as described in the first item under Modelling Approach above, the selection of deterministic parameters was done at the conservative end of the expected range of uncertainty, to provide calculations tending to overestimate expected results.

Conceptual road model:

4. USEPA: What is the generic composition (in more detail) of a road? For example, if road base is to be composed of a mixture of soil and PG, what are the ranges of composition of the soils to be used (e.g., organic carbon content, clay contents, moisture).

Arcadis: The Risk Assessment is intended to provide a conceptual exposure model of PG use in roads and is not linked to a specific road segment approval.

The selected example road was a four-lane county road with two lanes in each direction. This type of road is common in rural, suburban and urban settings and represents the type likely to be constructed by state and local governments who can employ PG during construction.

Choice of this road type permits evaluation of construction workers, nearby residents, bicyclists and motorists, and utility workers. The road dimensions are 15 m wide (about 12 feet [ft] per lane) and 100 m long (segment length) for modeling exposures. The thickness of the road base containing PG and road surface (i.e., pavement) are 0.25 m and 0.12 m respectively consistent with the EPA BID (1992).

The road base in the example road was selected to be PG mixed with in-situ soil, as it is the most probable choice to mix with PG. This soil would likely be used whether or not PG was used in the road base mix and is not considered as a risk variable. The soil-PG mixture will be compacted as part of the road construction process leading to high densities in the road base. Other site-specific soil parameters were not defined and are generally less important to the overall risk calculations. Specifically, carbon or clay content and moisture levels are not key factors in the risk determination (i.e., the radiation levels do not vary significantly based on these factors. Gamma ray attenuation for a fixed thickness of shielding is based on the density of the material being penetrated and to a lesser degree the chemical composition. The gamma source strength for a large slab of gamma emitting materials is proportional to the source strength (disintegrations per cc per sec) and inversely proportional to the mass attenuation coefficient[11]. The first term, source strength, can be rewritten as Bq/g x g/cc (pCi/g x g/cc). The second term, mass absorption coefficient is the linear attenuation coefficient divided by density. Both terms are dependent on density (i.e., g/cc or equivalent units). Thus, for practical purposes, the density of the source material is the key factor irrespective of the characteristics of the source material per se.

5. USEPA: What is the basis for limiting phosphogypsum to 50% in the road base? Is there a geotechnical reason, such that structural stability suffers at higher proportions? Is there an optimal range for durability? Alternatively, would administrative controls need to be put in place to maintain this limit during construction? Would an end-user need to address the administrative controls in a specific use request?

Arcadis: Available research on experimental roads reported PG:soil ratios in the range of 1:2 PG:Soil. The EPA in their 1992 BID used a 1:2 mix of PG:sand. This is also the PG ratio in the Polk and Columbia county roads[12] constructed with input on the design and testing of the roads from the University of Miami and the Bureau of Materials & Research, the Florida Department of Transportation.

[12] Chang, Wen F., and Mantell, Murray I., 1990. Engineering Properties and Construction Applications of Phosphogypsum, University of Miami, Phosphate Research Institute, ISBN No. 87024-328-4.

In a study by W.F. Chang et at (Chang, Wen F., Chin, David A., and Ho, Robert, 1989)[13], various ratios of PG to soil were studied. California Bearing Ratio CBR test were conducted on ratios of PG: sand ranging from 100% sand to 100% PG. The PG to sand mixtures showed all mixes had CBR values higher than sand or PG separately. Various radios of PG to soil were used in sections of an experimental road in Polk County Florida. The PG was rototilled into the soil to various depths, A portion was also covered by an asphalt coat. These studies indicate that there is no reason to limit the quantity of PG to be used in a road. The limiting factor would be the measured compressive strength and durability of the admixtures prior to their use in the road. Further studies could establish guidance on the range of PG to soil ratio allowed for various soil types. A 50:50 mixture of PG and local construction materials such as sand or soil is likely to be an overestimate of the actual mix

As noted in the figure below, road design parameters and specifications are better optimized at lower PG:soil ratios. To be conservative of potential risks, the risk assessment considered the upper end of likely reasonable mixture ratios. As stated in previous comments, this parameter provides a linear impact on the risk results. So, if alternate concentrations of PG are desirable, the risks can be easily extrapolated up or down from the existing calculations.

The amount of PG that would be used in a lane/mile of road base depends on many things such as: thickness of the road base, the percent PG in the road base, density of the PG, width of a "lane". In the end, the appropriate County, State or Federal road authority will have to approve the specifications of the road base used in the design. However, to illustrate the concept, consider a road where 1) lane width is 25 feet, 2) the maximum thickness of the road base mix is 12-inches, 3) the maximum percent PG in the road base is 50%, 4) the dry density/95% proctor can be based off the attached Figure 3.6 from Chang and Mantell 1990[14].

The Figure 3.6 Maximum density curve is based on a PG soil mix, it provides the highest density with PG at 1/6 of the mixture – which can then be extrapolated using the curve for a half/half mixture. Using this range yields a 95% proctor density of 1.9 to 1.98 grams/ cubic centimeter which converts to 118.6 to 123.6 lb/cubic ft.

That said, a 25 ft wide lane for one mile, would require about 3,900 to 4,100 tons of PG per mile, rounded to 4,000 tons/mile.

However, it is the concentration of Ra-226 in the road base that determines the gamma radiation levels. For example, a road with PG at 1/6 of the mixture as described above would have a Ra-226 concentration 3 times lower than the calculations provided in the 2019 risk assessment, and result in doses and risks 3 times lower. As previously indicated, the 2019 risk assessment assumed a 1:1 mix of PG and local soils. This is considered a reasonable upper bound for such a mixture and hence alternative mixtures will have lower concentrations of Ra-226 than were assessed in the 2019 risk assessment and hence, it follows that the doses and risks would also be lower.

36 PHOSPHOGYPSUM

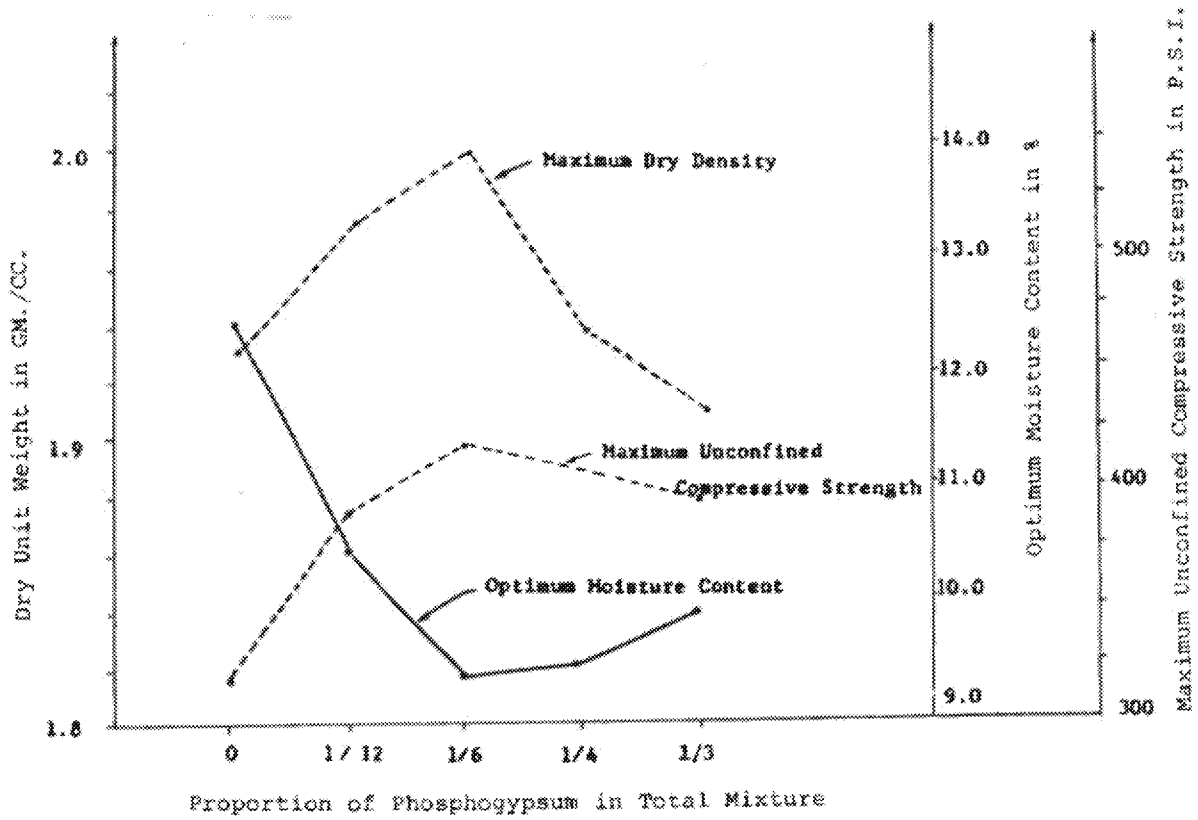

Figure 3.6 Variation in the maximum unconfined compressive strength, optimum moisture and maximum dry unit weight with change in the proportion of phosphogypsum in the various mixtures of clayey sand, sand and phosphogypsum.

6. USEPA: Reviewers had questions related to the conceptual model for the road design, specifically the restriction of the phosphogypsum-containing layer of road base to the area under the pavement. A road model used by the U.S. Federal Highway Administration, "Tech Brief: Bases and Subbases for Concrete Pavements," FHWA-HIF-16-005 (https://www.fhwa.dot.gov/pavement/concrete/pubs/hif16005.pdf) shows a road base which extends 3 to 4 feet (91 to 122 cm) beyond the road cover on each side of the road. In this case, all scenarios would need to account for some gamma exposure from road base material that is not shielded by pavement, and the possibility that phosphogypsum may become airborne at the uncovered edges of the road base.

Arcadis: The risk assessment provided an examination of a conceptual road design with risks estimated for scenarios and exposure pathways expected to be the most dominant. The road design in the risk assessment approximated road design characteristics and plausible exposure scenarios for various types of roads. While some large highways may have exposed shoulders, those roads are unlikely to have pedestrians, cyclists or houses in close proximity. Suburban and urban roads represented a plausible

scenario which maximizes exposures for the dominant external gamma pathway. Airborne dust from exposed shoulders is not expected to be a dominant pathway due to the binding properties of PG and the limited potential for substantive intake. Further, road shoulders typically become infilled with vegetation which also suppresses dust.

To explore this question, Arcadis considered the dose and risk impacts for a conceptual road with a 4-foot uncovered shoulder. We estimated results that are not substantially different from that of the original conceptual design of a 15-meter-wide road. Consider the worst case a worker at the center of the road. Gamma rays emitted from the strip (consider the leading or close edge or 7.5 m from the center) would need to travel at an extreme angle (~7.6 degrees) to impact a worker at the center of the road at the dose point (one meter above the surface. From the far edge (8.7 m form the center) the angle is 6.6 degrees. Assuming gamma rays are emitted isotropically, then about 1% of the additional emitted gamma rays (1/90) strike the worker.

Additional gamma calculations were also done with RESRAD for an uncovered road shoulder as described below to confirm the above estimations. Two cases were run with all the parameters fixed with the exception of the area. The original area was 15 m by 100 m, the adjusted area was 17.5 m by 100 m. Table 1 presents the exposure for a worker at the road center in both cases. As indicated the maximum contribution to the dose is external gamma. The increase in dose for external gamma is about 1.5%

Table 1 Dose to a maximumly-exposed worker at the center of a road with constructed with PG

	Direct exposure mrem/year	Inhalation dose mrem/year	Inhalation Dose mrem/year	Total Dose mrem/year
Original Road (15 m x 100 m)	26.11	0.1423	1.918	28.170
Adjusted Road (17.5 m x 100 m)	26.51	0.1465	2.004	28.661
Increase %	1.5%	2.9%	4.4%	1.7%

A similar calculation can be performed with the exposure point at the edge with similar results. The conclusion is that the 3- to 4-foot (i.e., 1 m to 1.2 m) strip along the road has minimal increase in the dose and final risk.

7. USEPA: Are assumptions related to durability and weathering of roads based on documented experience? What are the assumptions regarding the frequency of repaving or other road maintenance/replacement? Are they correlated to the type of road and traffic projections? Would an end-user need to account for such assumptions in a specific use request?

Arcadis: Road maintenance related to weathering roads was not explicitly assessed in the 2019 risk assessment, nor was road maintenance assessed in the EPA 1992 BID. This scenario is not deemed to be an RME condition and would be bounded by risks calculated for the Road Construction Worker. Consequently, road type and traffic projections are not relevant to the risk assessment and would not need to be accounted for in a specific use request.

Potential doses arising from road maintenance are expected to be on the order of those from the Utility Worker scenario. Full repaving activities would be limited to exposures less than those arising from road construction.

Road maintenance is typically done by milling the surface, cleaning, applying tackifier (to assist in binding new asphalt to the underlying asphalt) and new asphalt, leading to minimal disruption of the road base (the PG containing layer). Section 10.5.3 of IAEA 78 Safety Report Series[15] provides several observations on use of PG for road base and suggests PG roads would require less frequent maintenance as compared to roads constructed with other clay-based and limestone materials.

> *Phosphogypsum has successfully been used as a binder for base course mixtures. Phosphogypsum based mixtures are more workable than clay based mixtures. Delays due to rain during construction are reduced because the compacted mixture does not absorb significant amounts of water. Shrinkage cracks and swelling, which often negatively affect the performance of clay based road beds, are greatly reduced. The stability of compacted phosphogypsum mixtures is superior to that of clay mixtures [186] and there is evidence that the use of phosphogypsum, if correctly optimized, leads to a progressive strengthening of the road bed over time [214, 215].*

Further as regards maintenance to date experience indicates minimal maintenance.

> *In Florida, USA, two experimental roads were built in 1986–1987 using both dihydrate and hemihydrate forms of phosphogypsum [224, 225]. The results of the evaluations are reported in Refs [226–228]. It was concluded that phosphogypsum, when subjected to optimum mixing and compaction, could be transformed into a solid of high strength that is effective as a binder to stabilize on-site soil. Phosphogypsum and sand mixtures, stabilized with a small amount of cement, possessed a load bearing capacity higher than that of locally mined limestone, which was at that time the material of choice for road bases in the region. It was also demonstrated that the incorporation of phosphogypsum into a cement based mixture for making 'roller compacted concrete' (a form of concrete widely used for road construction) led to improved compaction and strength properties [229]. The road bed described in Ref. [224] is shown in Fig. 49, which shows the condition after 25 years of use. The picture was taken during routine resurfacing. While the phosphogypsum is clearly not mixed in fully with other road bed materials, it has, nevertheless, lost none of its load bearing strength. As a result, the only maintenance requirement was a new layer of asphalt.*

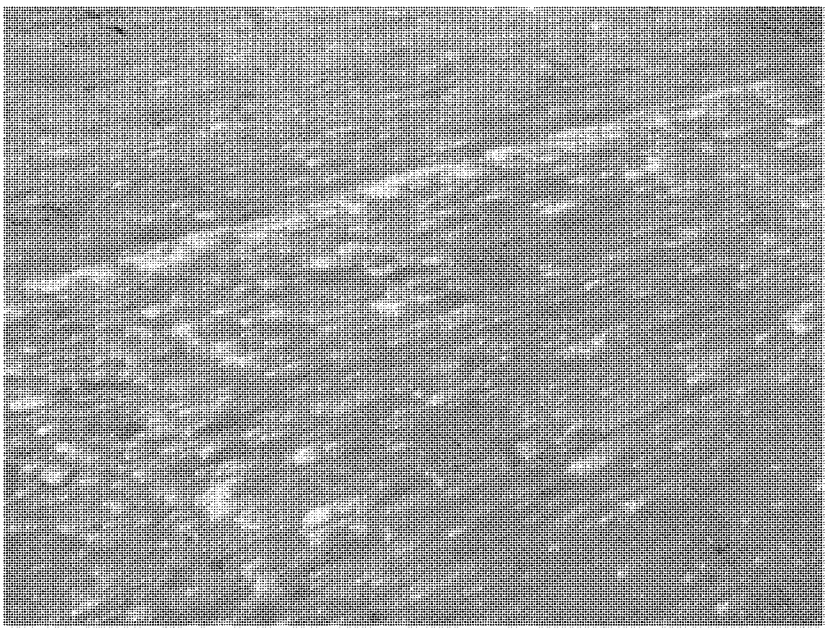

FIG. 49. Experimental road bed in Florida, USA, incorporating phosphogypsum (courtesy: Florida Industrial and Phosphate Research Institute).

In summary, the dose and risk from repairs conceptually cannot be greater than the dose and risk from the original road building since the PG is covered by concrete, asphalt or other material. The Risk Assessment provides the RME scenarios representing categories of exposure conditions with other minor exposure scenario representing lower risks. The example of road maintenance is not considered an RME and requires no further assessment.

Environmental and exposure pathways:

8. USEPA: The risk assessment would benefit from additional analysis of water pathways. Appendix 3 states that "Leaching to groundwater (or surface water) is likely not a complete exposure pathway for the petitioned PG reuse in road construction. This is because roadways are sloped to drain precipitation and paving will act as a barrier to infiltration through the compacted road base beneath. Despite this, literature regarding leaching and water quality was evaluated as part of this screening assessment (see the section titled "Leaching and Water Quality")." (p. 4) At least qualitative consideration should be given to direct contact with surface or groundwater due to flooding events, high water tables, and the presence of karst in phosphate lands. Likewise, reviewers suggested that the risk assessment consider the weathering of the road – will it develop fractures, potentially leading to infiltration resulting from road weathering cause leaching?

Arcadis: Previous risk assessments including 1992 Background Information Document for "Potential Uses of Phosphogypsum and Associated Risks", EPA 1992[16] and SENES 1997[17] examined the potential for impacts to groundwater and surface water pathways. These studies found no realistic potential for impacts to these pathways. Groundwater and surface water pathways were identified to be inconsequential by the EPA BID calculations. Radionuclides were not calculated to reach the nearby well water via the groundwater for almost 10,000 years. For off-site (more distant) wells and river water, radionuclides were not calculated to reach these waterbodies via groundwater for almost 100,000 years. The EPA BID reported in Note C, Table 4.15, that groundwater velocities and retardation factors in the modelling were the factors contributing to this result.

> *No radionuclides are calculated to reach the on-site well via the groundwater pathway for almost 10,000 years, or the off-site river or well for more than 100,000 years because of groundwater velocities and retardation factors.*

Exploratory calculations were completed by SENES Consultants Limited (1997) (now Arcadis Canada Inc.) to review how EPA calculations for the Background Information Document (BID) and Final Rule. SENES reconstructed the BID calculations with nearly identical results as shown in Table A.1 from SENES 1997. With respect to water pathways, the results were consistent, showing that there was no impacts or very limited results, orders of magnitude below other pathways of interest, as shown in the table.

Table A.1

BID RECONSTRUCTION RESULTS
(Asphalt Road Constructed Using Phosphogypsum Containing Radium-226 At 26 pCi/g)

	Comparison of BID results and reconstructed results Dose, mrem per year (Lifetime risk per year of exposure)	
	BID Dose(Risk)	BID Reconstruction Dose(Risk)
Construction Worker		
- gamma no shielding from equipment	41 (1.5×10^{-5})	42 (1.3×10^{-5})
- gamma with shielding from equipment	25 (9.0×10^{-6})	25 (7.6×10^{-6})
- inhalation of dust - dry site	2.5 (2.2×10^{-7})	2.5 (2.1×10^{-7})
- inhalation of dust - humid site	1.0 (8.4×10^{-8})	1.0 (8.6×10^{-8})
Person driving on road		
- gamma	0.22 (8.2×10^{-8})	0.23 (7.2×10^{-8})
Critical Population Group		
- gamma, 100 m off-site	0.043 (1.6×10^{-8})	$<1.0 \times 10^{-7}$ ($<1.0 \times 10^{-13}$)[a]
- ingestion of well water	---[c]	0.0037 (8.2×10^{-10})[b]
- ingestion of food	---[c]	---[b]
Off-site Individual		
- river water from groundwater	---[c]	---[c]
- river water from surface runoff	0.02 (1.5×10^{-8})	0.02 (2.2×10^{-9})

Notes:

a. Critical Population Group gamma dose estimates are less than the stated values. These values were calculated in MicroShield without taking account of shielding provided by the upper layer of road material. Risks for this pathway are calculated based on a risk factor of approximately 3.9×10^{-7} $mrem^{-1}$ (EPA 1989). As MicroShield does not provide radionuclide-specific doses, this alternative approach to the risk calculation was utilized. For further information see Part II, Section 3.3.

b. The values stated for well water ingestion by the CPG correspond to year 10,000. No radionuclides were calculated to reach the well water in any of the prior years that were calculated. The food pathway for the CPG was not modelled as it is expected to have a similar result, or less, than the well water pathway. This is based on the BID assumption that food eaten by the CPG is irrigated with well water.

c. For these pathways, no radionuclides were calculated to reach the on-site well via the groundwater pathway for almost 10,000 years, or the off-site river or well for more than 100,000 years because of groundwater velocities and retardation factors.

9. USEPA: Related to the question of whether interactions with ground and surface water are possible, if dissolution or leaching does take place, is there a potential for uptake and bioaccumulation by organisms of any of the radiological constituents of phosphogypsum?

Arcadis: As noted above, radiological groundwater and surface water impacts were not expected to be relevant in the overall risk determinations for this potential use of PG. By extension subsequent

pathways to groundwater and surface water were shown not to be relevant, as documented in BID 1992, Table 4-15 and SENES 1997, summarized in Table A.1 above.

Exposure scenarios/receptors:

10. USEPA: The risk assessment should address the handling of the phosphogypsum between the stack and road construction. The risk assessment should incorporate all handling and processing steps necessary to implement the use. Presumably, pure phosphogypsum would be trucked to a batch plant or other mixing facility, prior to transportation to the construction area. These scenarios should be explicitly considered, including the potential for dust and surface runoff.

Arcadis: Known construction procedures involve PG mixing at the road construction site by placing the PG in the desired location and mixing it into existing or additional soil. Existing calculations consider dust generation at the construction site. These dust intake pathways were found to be orders of magnitude less than external gamma exposure for the construction worker. PG is not batched or mixed prior to use. With respect to loading PG in a truck, the frontend loaders and/or scrapers used to remove PG from a stack to a holding area stockpile at the plant facility for subsequent loading are closed air-conditioned cabs.

Any potential dust exposure to the truck driver or equipment operator is expected to be substantially less in concentration and duration of exposure, compared to the construction worker

For example, as can be seen in the RESRAD output in Appendix C of the Draft Risk Assessment, the annual dose for a road construction worker at the center of the road working on exposed road base, who would experience more direct exposure than a truck driver, inhalation exposure represents 0.5% of the total annual dose. This is presented in the table below.

Road Construction Worker Uranium-238 Dose Exposed to Road Base at Center of Road			
Total Annual Dose (mrem/year)	External Gamma (mrem/year)	Inhalation (mrem/year)	Incidental Ingestion (mrem/year)
28.17	26.11	0.1423	1.918
100.0%	92.7%	0.5%	6.8%

Consequently, the contribution of dust intake for the truck driver or equipment operator is not expected to be relevant to the overall dose and risk calculation.

In addition, consider potential gamma exposures as illustrated by an equipment operator loading the truck using a medium frontend loader. The rate of loading for a 2.25 cubic yards (cy) capacity bucket is 100 cy/hour (Means 2000). Assuming the operator fills ten 20 cy trucks results in an exposure time of two hours per day. In addition, the operator of the front-end loader would be inside a cab located above the PG stack and shielded by the cab. The cab shielding (1 cm of steel) reduces the gamma dose by 50%. This results in the cab operator receiving an annual dose of about 10 % of the construction worker dose (25% exposure duration-2 hours/day and less than 50 % of the gamma dose). The risk is also reduced by at minimum a factor of ten.

11. USEPA: The truck driver scenario only includes direct external exposure from gamma radiation. It should explicitly consider inhalation or ingestion during loading, unloading and truck cleaning.

Arcadis: See comments above. While these additional exposures can be developed, given the discussion in the previous comment, we see no realistic potential for a substantive increase in the calculated risk due to inhalation and ingestion of dust. As described in the response to comment 10, the annual dose for a road construction worker at the center of the road working on exposed road base, who would experience more direct exposure than a truck driver, inhalation exposure represents 0.5% of the total annual dose and ingestion represents 6.8% of the total dose. As a truck driver in the cab of a truck would have less exposure via these routes of exposure than a road construction worker, the relatively small incremental increase in dose has little impact on the resulting risk estimate. Assuming similar percentages for inhalation (0.5%) and incidental ingestion (6.8%) for the truck driver scenario with an annual dose of 18.6 mrem/year, inhalation would be 0.09 mrem/year and ingestion would be 1.27 mrem/year for a total of 20 mrem/year. However, ultimately once converted to risk over a 5-year exposure duration the resulting cancer risk (presented to one significant figure) remains the same (i.e., 20 mrem/year divided by 1,000 mrem/rem, multiplied by the cancer risk coefficient of 5.0×10^{-4} per rem = 5×10^{-5}).

12. USEPA: The utility worker scenario should consider a worker in a trench that parallels the road, rather than crossing it.

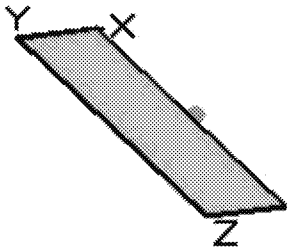
Arcadis: For the Utility Worker Arcadis selected a trench that crosses the road to simply represent an RME scenario, providing a near upper-limit exposure. This scenario provides exposure to an excavated surface on both sides of the worker. The exposure rate as reported in the Risk Assessment is 4.2 µR/hr.

Considering a trench that parallels the road on either side provides only one exposed surface. The result is an exposure rate approximately half (2.15 µR/hr) of the exposure rate arising from the trench considered in the 2019 Risk Assessment. Below are excerpts of a MicroShield output for a trench along the length of the road.

MicroShield Output for Trench Along Length of Road

Source Dimensions	
Length	1.5e+3 cm (49 ft 2.6 in)
Width	1.0e+4 cm (328 ft 1.0 in)
Height	25.0 cm (9.8 in)

Dose Points			
A	X	Y	Z
#1	1.6e+3 cm (51 ft 10.8 in)	25.0 cm (9.8 in)	5.0e+3 cm (164 ft 0.5 in)
#2	1.6e+3 cm (52 ft 10.8 in)	25.0 cm (9.8 in)	5.0e+3 cm (164 ft 0.5 in)
#3	1.6e+3 cm (53 ft 10.8 in)	25.0 cm (9.8 in)	5.0e+3 cm (164 ft 0.5 in)



Shields			
Shield N	Dimension	Material	Density
Source	1.32e+04 ft³	Concrete	2.25
Air Gap		Air	0.00122

Results - Dose Point # 1 - (51.9,8.20e-01,1.64e+02) ft					
Energy (MeV)	Activity (Photons/sec)	Fluence Rate MeV/cm²/sec	Fluence Rate MeV/cm²/sec	Exposure Rate mR/hr	Exposure Rate mR/hr
		No Buildup	With Buildup	No Buildup	With Buildup
Totals	**1.111e+09**	**5.692e-01**	**1.237e+00**	**9.726e-04**	**2.149e-03**

In the extremely unlikely scenario of a 100 m trench down the center of the road, the resulting exposure rate is estimated by assuming two exposed surfaces results in an exposure rate of 4.3 µR/hr. The incremental length of the trench provides no substantive increase in dose rate due to the extreme angle and distance of the additional exposed surface.

13. USEPA: There may be road user scenarios worth considering, particularly if phosphogypsum may extend beyond the paved areas, e.g., pickup/delivery drivers, workers who mow the shoulders. How would these compare to the currently-modeled scenarios?

Arcadis: As discussed in a previous question, the risk assessment provided an examination of a conceptual road design with risks estimated for scenarios and exposure pathways expected to be the most dominant. The examined exposure scenarios were included in the risk assessment in order to provide the likely maximum scenarios and the scenarios were agreed to by EPA.

The conceptual road design in the risk assessment approximated road design characteristics common in rural, suburban and urban settings and provided plausible exposure scenarios for various types of roads. While larger highway designs could be built, these require larger right-of-way widths of approximately 150 to 300 feet.[18] This leads to larger set-backs for near-by residential housing, resulting in lower dose and risk. Interstate highways typically have restricted access to cyclists and pedestrians, eliminating these

[18] The Federal Highway Administation, Highway History, The Size of the Job, available at https://www.fhwa.dot.gov/infrastructure/50size.cfm

exposure scenarios for large highways. Suburban and urban roads represented a plausible scenario which maximizes exposures for the dominant external gamma pathway.

With respect to pickup/delivery drivers and workers who mow the shoulders the dose assessments for road users provided in the 2019 risk assessment would be bounding and estimate higher doses than doses for other types of road users.

For example, a truck driver may drive 50% of the workday but would likely be on PG road only 25% of the driving hours due to the use of the extensive network of existing roads. Drivers in delivery trucks would also gain the benefit of shielding from the vehicle structure, which is typically a factor of approximately 0.6 (BID 1992). Overall, a scenario with a delivery driver is estimated to result in a dose that is approximately 30% of that estimated for the road user in the 2019 risk assessment.

A worker mowing the grass beside the road may be working for close to a full day but again would likely be beside a PG road only 25% of the driving hours due to the work on the extensive network of existing roads. This worker would also gain the benefit of shielding from the vehicle structure, which is typically a factor of approximately 0.6 (BID 1992). Considering the worker is located beside the road, the exposure to PG is reduced by approximately 50%, as shown in the 1992 risk assessment. Overall, a scenario with a worker mowing grass beside the road is estimated to result in a dose that is approximately 30% of that estimated for the road user in the 2019 risk assessment.

Parameters:

14. USEPA: The worker exposure duration of 5 years is based on both 25% of a 20-year career and of 70% of the project completion time for a major road project (p. 2-9). If the use of phosphogypsum as road base becomes regular practice, would workers not be expected to work on subsequent projects that could also involve phosphogypsum?

Arcadis: The road construction project examples provided in the discussion of this parameter were some of the largest (longest) projects identified. The parameter estimation uses worker statistics and the likelihood of other road construction methods to continue, to estimate a reasonable exposure duration over a construction worker's career.

The Bureau of Labor Statistics employee tenure in 2018 shows that the median years of tenure with current employer for construction industry between 2008-2018 ranges from 3.5 years in January 2008 to 4.3 years in January 2012 (See Table 5 below).

Table 5. Median years of tenure with current employer for employed wage and salary workers by industry, selected years, 2008-2018

Industry	January 2008	January 2010	January 2012	January 2014	January 2016	January 2018
Total, 16 years and over	4.1	4.4	4.6	4.6	4.2	4.2
Private sector	3.6	4.0	4.2	4.1	3.7	3.8
Agriculture and related industries	4.3	4.8	4.1	3.6	4.5	4.6
Nonagricultural industries	3.6	4.0	4.2	4.1	3.7	3.8
Mining, quarrying, and oil and gas extraction	4.1	4.8	3.5	4.0	4.6	5.1
Construction	3.5	4.2	4.3	3.9	4.0	4.1

Burmaster (2000)[19] analyzed employee tenure data from The Bureau of Labor data. The report provides statistical analysis of those data for a wide variety of occupations. For construction in general, the data for men (women not available) show a mean and 95th percentile of 3.23 yr and 12.48 yr. For construction laborer's specifically, the data for men/women show a mean and 95th percentile of 1.74 yr / 1.81 yr and 5.93 yr / 7.08 yr, respectively.

Burmaster (2000) also provides the distributions (in terms of empirical percentiles) for projected duration in years for each occupation type. The table below shows the worker tenure percentile projections for these selected industrial subsectors.

Distribution of Male Worker Tenure by Industry Type

Industry Sector		Percentiles											
	Mean	10	20	30	40	50	60	70	80	90	95	97.5	99
Construction	3.23	0.21	0.45	0.74	1.10	1.54	2.13	2.98	4.39	7.70	12.48	18.24	26.23
Construction Labor	1.74	0.10	0.22	0.36	0.53	0.74	1.01	1.40	2.03	3.45	5.93	11.53	21.26

To be consistent with methodologies to determine RME exposures and risk Arcadis considered that not all construction work will be on PG roads due to possible alternate construction methods and maintenance work for the vast network of existing roads.

The value used in the Risk Assessment represents a portion of industry tenure spent constructing roads: 80% of 25-year worker tenure recommended by USEPA (2014) constructing roads = 20 years; 25% of road construction time spent using PG = 5 years. Based on the employment statistics provide above the actual exposure is likely to be much less than 5 years.

15. USEPA: The TFI Risk Assessment for the Truck Driver scenario uses a density of 1.12 gm/cm3 for phosphogypsum in the truck. U.S. Department of Transportation, Federal Highway Administration, Research and Development Turner-Fairbank Highway Research Center, User Guidelines for Waste and By-Product Material in Pavement Construction, FHWA-RD-97-148 gives a specific gravity range from 2.3 – 2.6 gm/cm3 (p. 19-6), and in a second location states, "specific gravity of solids ranges from 2.30 to 2.50, with an average in the 2.35 to 2.40 range." (p. 19-14). TFI assumes that loose PG in the truck will be about half the density of that identified in the FHWA document. PG that is excavated and loosely placed in a truck will certainly have a higher porosity, but what is the basis for assuming this specific value?

Arcadis: The specific gravity values of 2.3 to 2.6 (unitless) are common in literature about PG. For example, Chang and Mantell 1990[20], reported the average specific gravity values of seven Florida

---

[19] Burmaster, David E., 2000, *Distributions of Total Job Tenure for Men and Women in Selected Industries and Occupations in the United States, February 1996*. Risk Analysis, Vol. 20, No. 2, 2000.
[20] Chang, Wen F., and Mantell, Murray I., 1990. Engineering Properties and Construction Applications of Phosphogypsum, University of Miami, Phosphate Research Institute, ISBN No. 87024-328-4.

sources of PG varied between 2.33 and 2.43. The specific gravity values of this magnitude however related to particle specific gravity and ignores the porosity / void space in the bulk material. The same reference reports the maximum dry bulk density of PG following compaction to range between 90.3 to 102.7 lb/ft^3. This compacted bulk density converts to 1.4 to 1.6 g/cm^3. For material excavated and loaded into a truck a swell factor of 20% - 30% is not uncommon for materials such as soil, sand or gravel. For the Risk Assessment the density of the PG in the truck can be supported using a bulk density of 1.4 g/cm^3 with a swell factor of 25% (1.4/1.25) resulting in PG density during transport of approximately 1.12 g/cm^3.

As previously indicated, density is an important factor in assessing potential doses arising from road building. The in-place post compaction density of PG in road base will be specified along with other physical characteristics by the appropriate local, state or federal highway authority. The densities used in the current (2019) risk assessment are considered appropriate for the purpose of risk assessment.

16. USEPA: Assumed inhalation rates may need further justification. As stated in the TFI Appendix 2 (p. 2-11): "The RESRAD default inhalation rate of 8,400 cubic meters per year (m3/yr) was used for the nearby resident receptor. A higher inhalation rate of 11,400 m3/yr was assumed for road construction workers and utility workers. This value was the RESRAD version 6 default for industrial workers and assumes an hourly rate of 1.3 m3/hr." When 11,400 m3/yr is multiplied by the fraction of time spent outdoors (on site) the result is the Road Construction Worker annual inhalation rate of 2,622 m3/yr. This value is about 9% larger than the worker inhalation rate used by the International Commission on Radiation Protection (Guide for the Practical Application of the ICRP Human Respiratory Tract Model, 2002). However, compared to the EPA Exposures Factors Handbook (EPA 2011) Tables 6-1 and 6-28, the inhalation rates for moderate and heavy activities, the RESRAD rate of 1.3 m3/hr is lower than the low end of the range provided for EFH worker inhalation rate. The low end of the range is 1.6 m3/hr and the high end is 4.8 m3/hr, several times higher than the RESRAD rate.

Arcadis: RESRAD exposure parameters for workers were applied where available. Considering the exposure duration of a full day, it is expected that a moderate inhalation rate would be more realistic of the overall inhalation rate as heavy activities would not be continuous throughout the day. The values in Table 6-28 of EPA Exposure Factors Handbook (EPA 2011) ranging from 1.6 m^3/hr for the low end of the moderate activity level, which is for adult females, to 4.8 m^3/hour for the high end of the heavy activity level, which is for adult males, is based on information included in a dated guidance document (i.e., EPA 1985).

More recent studies are referenced in the Exposure Factors Handbook (EPA 2011), several of which were specifically conducted on workers or more specifically construction workers. One study of "high risk" populations exposed to ozone in the Los Angeles area found a mean inhalation rate of 0.78 m^3/hour for healthy adults and a mean of 1.5 m^3/hour for construction workers during a 10-hour work shift (Linn et al. 1992). Linn et al. (1993) studied inhalation rates of construction workers (i.e., laborers, iron workers, and carpenters) during work and break times based on a relationship to heart rate and determined a mean inhalation rate of 1.68 m^3/hour with a standard deviation of ± 0.72. However, estimates of extremes (e.g., 99th percentile) were outside the calibration range of the model and would not be appropriate for an RME. Lastly Allan et al. (2009) determined mean inhalation rates of 1.4 m^3/hour for male construction workers and 1.25 m^3/hour for female construction workers based on probability density distributions generated using Monte Carlo simulation. Therefore, the inhalation rates used which are based on RESRAD defaults are appropriate mean estimates.

While upper percentile estimates may represent a relative extreme, those assumptions are not appropriate for a reasonable maximum exposure scenario. Regardless, using an inhalation rate up to 3 times higher resulting in inhalation doses 3 times higher would still add relatively little to the overall dose and risk as the inhalation route of exposure results in a dose that is orders of magnitude less than external radiation and an order of magnitude or more less than ingestion exposure.

17. USEPA: It is difficult to evaluate the appropriateness of the worker exposure parameters TFI used in Appendix 2, in part due to a lack of detail in discussion of road base and pavement construction process, procedures, and equipment. Page 3-2 states "it was assumed the road construction worker moves around the surface of the road and the direct dose was calculated as the average of the dose at the road center and at the edge of the road." Would different workers have different roles, such as walking directly behind machinery versus walking on the road shoulder? What would happen to the doses if this ratio was changed, such as 75% middle of the road/ 25% edge?

Arcadis: The assumption of the construction worker exposure at both the center of the road and the edge of the road approximates the expected movement of a worker throughout a full workday. Shifting this parameter to the extreme of working 100% of the time in the center of the road would provide a minor increase in the exposure and risk.

As shown in the calculations in a previous question above, assuming the worker spends 100% of the time in the center of the road provides an annual exposure of 28 mrem/yr. This is a 27% increase from the 22 mrem/yr exposure reported in the risk assessment, based on 50% in the middle of the road and 50% along the edge of the road, but makes no change to conclusion that the risk is significantly below 3:10,000. But it is unrealistic to assume a work stands in one spot all day. If a worker did so, he or she would have a very low inhalation rate.

Subject:
Responses to Second Set of USEPA Questions - Reclaimer

This memorandum responds to the technical comments and questions to TFI dated March 6, 2020 from the United States Environmental Protection Agency (USEPA). The questions from the USEPA relate to the Reclaimer calculations described in the risk assessment report submitted in October 2019[1] as support to the petition for beneficial use of phosphogypsum. For each paragraph provided by USEPA in their questions, Arcadis has provided a response below.

However, initially, this Response provides the relevant background, the probability of abandoning a road constructed with PG, an assessment of whether the USEPA BID Reclaimer Scenario is a reasonable maximum exposure (RME), and the Hypothetical Reclaimer Scenario in the October 2019 Risk Assessment.

Background

The USEPA BID risk assessment considered a scenario with exposures from gamma radiation and radon over a 70-year period, in which just the road surface is removed, no land preparation is performed, and a house is directly built directly upon PG amended road base material.

The October 2019 Risk Assessment concluded:

> The RME for ultimate disposition of a new road constructed with PG is that it serves as an established part of municipal (county, state and/or federal) infrastructure and as such would require periodic repair and expansion as needed. These activities could include removing the surface, grinding and reusing or disposing of the materials consistent with federal and state and local regulations. Exposures and risks associated with maintenance of roads and reuse of

---

[1] Arcadis 2019. *Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum*, Report to The Fertilizer Institute, October.

construction materials are expected to be comparable or less than those detailed in the risk assessment for road construction. It is also noted that as part of road construction, no excess PG is expected to be left over. Road builders avoid transporting extra material to a construction site and would mix in any remaining PG to avoid additional handling.

TFI had Arcadis include a "Reclaimer" scenario in the October 2019 Risk Assessment in the risk assessment in part to document the reasons it was not a RME ultimate disposal option and because USEPA requested that we perform an assessment of the risk for this extreme scenario. It is TFI's understanding that USEPA requested this scenario because it was used by EPA in 1992.

The Probability of Abandoning a Road Constructed with PG

The initial question is, what is the probability of a road constructed with PG will be abandoned.

The Revised Petition includes a summary of the legal framework involved in abandoning a road. This Response include a summary of that legal background to provide context). There are legal, practical, and economic obstacles to abandoning a road.

First, federal regulations govern abandoning a federal road and state transportation laws govern abandoning state and local roads. Since roadways serve a public use (i.e., providing access of citizens of each state to the broader community), these laws, regulations and policies are designed to make it difficult to abandon roads.

Second, roads act as preferential pathways for placement of utilities and other economically important services. Abandoning a road effectively abandons those other societal benefits.

Third, Federal, State, and local roads are sited and maintained to support the federal, state, and local land use requirements. Abandoning a road ignores those broader societal goals.

Finally, the Reclaimer scenario of building a house on top of an abandoned roadway is not consistent with typical land re-use and sustainability policies, is limited by the legal constraints on abandoned public roads, is extremely rare (research has found few, if any, examples. Therefore it is not a reasonably anticipated land use).

Assessing Whether the USEPA BID Reclaimer Scenario Is an RME

The next question is whether the USEPA BID Reclaimer scenario is an RME. The RME is the exposure level utilized in USEPA risk assessments (see the TFI Revised Petition which summarizes the USEPA requirement for using high end, but realistic scenarios).

Even on the face of the 1992 USEPA BID, a 70-year period for the duration of residential exposure is beyond the RME, because the 1992 USEPA BID used 25 years as the duration of a resident's exposure for the nearby resident. Additionally, USEPA's current RME for the duration of residential exposure is 26 years (specifically a 90th percentile of exposure), precisely because "USEPA has been criticized for too

often assuming that future use will be residential" and other unrealistic assumptions.[1] As described above, road abandonment is rare and requires a formal legal process.

In summary, the 1992 BID risk assessment's so called reclaimer scenarios is an extreme scenario well beyond an RME assumption and represents an extreme situation that is unlikely to even occur as described.

The Ultimate Disposition Scenarios Is Repair of the Road

The use of this extreme scenario does not mean it is a RME for ultimate disposition. More realistic situations for the ultimate disposition of the road include continued use of the road as a road, or reuse of the PG road base for a new road, if the road was to be relocated or realigned.

As required by USEPA, the October 2019 Risk Assessment assumed arbitrarily that a road which was constructed is reused for residential purposes, the land preparation activities will realistically result in blending and mixing of the road base to levels that are indistinguishable from background levels.

The October 2019 Risk Assessment, the Response to USEPA's Comments on January 16, 2020, and this Response document that the ultimate disposition is that the road serves as an established part of municipal (county, state and/or federal) infrastructure and as such would require periodic repair and expansion as needed. Below we address disposal of PG road material, if any.

The Hypothetic Reclaimer Scenario in the October 2019 Risk Assessment

To address USEPA's request, therefore, the Petition includes a hypothetical scenario which the risk analysis concludes is an extreme exposure (Extreme Reclaimer), i.e., the exposure is much higher than an RME exposure scenario. That hypothetical scenario assumes a home is built directly on an abandoned PG road, a construction scenario that would likely never occur under existing road construction practices and constraints on future land use for public infrastructure and therefore, the assumed scenario is not an RME scenario (N.B.: Note the distinction between an RME scenario and an individual assumption that is used to calculate the exposure in an RME scenario). The exposure assumptions utilized are more realistic, but high end, assumptions. As discussed above, this scenario does not occur with a sufficient frequency to qualify as a RME scenario, however, the October 2019 Risk Assessment utilized USEPA's 26 years of residence RME assumption (i.e., the 90th percentile). Although this scenario also meets the USEPA risk management limit of 3 in 10,000, it is not an RME and therefore should not represent a condition of approval.

<u>Comment-by-Comment Response</u>

USEPA:

1. One of the key assumptions for the Reclaimer Exposure Scenario identified in the TFI risk assessment, Section 3.4.1 is: *Site grading for construction will almost certainly reduce the*

[1] EPA Land Use in the CERCLA Remedy Selection Process at (OSWER Dir. No. 9344.7-04).

thickness of the layer containing PG; however, for present purposes, we have assumed that site preparation will reduce the PG layer to about 10 centimeters (cm) in thickness and the concentration of Ra-226 in the remaining layer to about 10 pCi/g. No justification is provided for either of these specific values, beyond the risk assessment's description of site grading as a means for reducing the PG layer thickness and concentration. Please provide either a technical justification of how the 10 cm thickness and 10 pCi/g values were derived, or a sensitivity analysis that shows why they are bounding.

Arcadis: As noted above the Reclaimer scenario is an unlikely extreme scenario. Despite this, the scenario was created applying current or future building practices. The Florida Building Code[1] for example requires that slab on grade homes are constructed to certain specifications. Footings are to be supported on undisturbed natural soils or engineered fill. Concrete slab-on-ground floors need to be a minimum 3½ inches (89 mm) thick. The area within the foundation walls under the floor shall have all vegetation, top-soil and foreign material removed. Fill material shall be free of vegetation and foreign material. The fill shall be compacted to ensure uniform support of the slab, and except where approved, the fill depths shall not exceed 24 inches (610 mm) for clean sand or gravel and 8 inches (203 mm) for earth. As a base below the fill material, the building code requires a 4-inch-thick (102 mm) base course consisting of clean graded sand, gravel, crushed stone, crushed concrete or crushed blast-furnace slag meeting specific engineered standards.

These building code requirements are deemed to be reasonable estimates of future requirements for slab-on-grade buildings. In the extremely unlikely event that a Reclaimer home were constructed on an abandoned road, the building code requirements would impose specific actions be taken to prepare the subsurface as described above. In practice, this is expected to eliminate all of the PG road base from beneath the home. Consequently, it is likely the dominant risk pathways associated with the Reclaimer would be eliminated.

For conservativeness and in an effort to respect the USEPA request to examine this scenario, it was assumed that a mixture of the PG in soil was re-introduced into the construction process beneath the floor. Admittedly subjective, the parameters for the PG amended layer and the associated concentration of radium-226, were set at 10 cm and 10 pCi/g which is nearly the maximum radium-226 concentration used for road base in the risk assessment. This estimate is still an extreme assumption, considering the discussion above concerning building code requirements.

USEPA:

2. Arcadis calculates external dose to the reclaimer (due to ground shine through the home foundation) using RESRAD, rather than MicroShield. A foundation thickness of 20 cm was specified in the RESRAD input (Arcadis 2019, pdf page 229), rather than the 10 cm specified on page 3-9. This appears to take credit for a 10 cm granular fill layer that is shown in Arcadis 2019, Figure 3.1, but is not otherwise discussed. Please provide a technical justification for the presence of clean fill.

---

[1] 2017 Florida Building Code - Residential, Sixth Edition. (https://codes.iccsafe.org/content/FRC2017)

Arcadis: As noted in the above question and response, the Florida Building Code represents a reasonable set of expectations for future building requirements. For slab-on-grade homes the foundation and sub-floor ground preparation requirements can reasonably be expected to essentially eliminate all the PG road base from beneath the home. Consequently, it is likely the risks associated with the Reclaimer would be eliminated.

If in the extreme case, a mixture of the PG in soil was reintroduced into the construction process beneath the floor, the building code requirements would result in approximately a 10 cm concrete slab supported upon approximately 10 cm of engineered fill.

USEPA:

3. No other reclaimer exposure pathways beyond indoor radon and gamma dose were analyzed, e.g., ground shine from time spent in the yard, inhalation and soil ingestion from working in the garden, consumption of vegetables grown in the garden, consuming water from an onsite well. For example, in addition to radon diffusing through the floor slab, the EPA in 1992 evaluated both of these latter two pathways as potentially contributing to the reclaimer's dose: *The reclaimer is assumed to build a house on the roadbed at some future time after the road is closed and the road surface has crumbled and been removed. In addition to living in a house at the site, the reclaimer drills a well for water and plants a vegetable garden in the contaminated soil. The vegetable garden provides 50 percent of the reclaimer's foodstuffs.* (EPA 1992, page 4-10) The EPA's risk assessment showed these pathways to be minor contributions to the overall dose. If numerical results are not included, these pathways should at least be discussed.

Arcadis: Based on USEPA's request to include the Reclaimer scenario, Arcadis assessed the external gamma and radon pathways. Arcadis focused on the most significant pathways for this scenario.

As indicated by USEPA, the USEPA's 1992 BID[2] demonstrated that almost all of the estimated risk from the hypothetical reclaimer scenario is from external gamma radiation and the inhalation of radon (and its short-lived decay products) indoors. To illustrate, the risks from these two pathways are more than 1,000 times larger than the risks from for example, drinking well water or consuming foods grown in the phosphate amended soils. The exposure pathways other than gamma and radon are for practical purposes trivial and do not require further assessment.

The pathways ground shine from time spent in the yard, inhalation and soil ingestion from working in the garden, consumption of vegetables grown in the garden, consuming water from an onsite well were not considered as their contribution can be considered de minimis. In order to have a yard or a garden topsoil to depth of approximately one foot is typically required to grow grass or vegetables. This negates inhalation and ingestion, reduces ground shine by a factor of close to ten. In addition, most vegetables are shallow root, there will be little radium uptake into the plants. As regards the on-site well, leaching of radium into ground water wells was discounted in the 1992 BID.

---

[2] United States Environmental Protection Agency. Potential Uses of Phosphogypsum and Associated Risks – Background Information Document. Air and Radiation (ANR-459), 402-R92-002, May 1992.

From 2019 risk assessment: NCRP 160 also indicates that typical outdoor levels of radon are about 15 Bq/m^3 or 0.4 pCi/L. Thus, the predicted incremental indoor radon level attributable to PG under the home is small by comparison to either the variation in indoor levels or the typical outdoor level of ambient radon.

USEPA:

4. On page 3-10 Arcadis reports an estimated radon flux into the home of .009 pCi/m^2-s. Several parameters were selected which could potentially lead to an underestimate of this value, and some errors are present in the spreadsheet calculation:

   - Radon surface flux is calculated by Arcadis in Figure 3.2. The calculation is performed using a radon diffusion coefficient for the foundation of 4×10^{-4} cm^2/s (from Chauhan and Kumar 2015), and an emanation factor of .062 (Rogers et al 1994 and Chauhan 2015) for intact concrete, and formulas found in US NRC Reg Guide 3.64. The RESRAD default radon diffusion coefficient is an order of magnitude higher, at $3\text{x}10^{-3}$ cm^2/s: *The 3.0×10^{-7} m^2/s default radon diffusion coefficient for the concrete slab is a conservative value compared with the value of 6.0×10^{-9} m^2/s used by the U.S. Nuclear Regulatory Commission (…). It is used to account for possible cracks and other penetrations that may develop in the foundation as the house ages.* (ANL 2001, p. C-12) The RESRAD default emanation factor is .25, half an order of magnitude higher. Using the RESRAD default values results in a radon flux at the surface that is approximately an order of magnitude higher than the value reported by Arcadis. Substituting these low numbers for default values requires additional technical justification.

     Arcadis: There are a number of published values for radon diffusion coefficients. As the reclaimer scenario is not considered to be a (realistically) credible scenario, a detailed evaluation of diffusion coefficients was not performed. However, we point out that Table 7.1 of Yu et. al. 1993[3] provides a review of radon diffusion coefficients. The value of 4×10^{-4} cm^2/s is central to the values reported by Yu et. al. (1993) and considered suitable for the screening analysis provided in the current risk assessment.

     There are considerable data on the emanation coefficient of 0.062 used in the current assessment (as captured in the radon flux calculations) and is in the range of published emanation coefficients. The emanation factor of 0.062 used in this assessment is from a paper

[3] ANUEAIS-8 Data Collection Handbook to Support Modeling the Impacts of Radioactive Material in Soil by C. Yu, C. Loureiro,* J.-J. Cheng, L.G. Jones, Y.Y. Wang, Y.P. Chia,* and E. Faillace, Environmental Assessment and Information Sciences Division, Argonne National Laboratory, 9700 South Cass Avenue, Argonne, Illinois 60439.

by Vern Rogers[4], specific to concrete in Florida construction (experimentally determined) and in our view appropriate.

- In the spreadsheet provided by Arcadis, the term $\sqrt{a_b/a_f}$ from Reg Guide 3.64 Equation 12 was not included. By disregarding this term, Arcadis' calculation does not account for differences between the porosity, radon diffusion coefficient, and moisture content of the foundation and underlying layers.

  Arcadis: There are no terms in equation 12 "a_b" or "ar". It is assumed the terms cited should be "ai" and "a_c" the interface coefficients. As the basis for this case assumed approximately the same diffusion coefficient, porosity and moisture saturation fraction, the ratio is unity and this term can be ignored in the multiplication. Additionally , the screening analysis considered the effect of this factor which as USEPA notes is intended to adjust for the differences in media (a sort of "transition from one media to another) to be inconsequential and on the order of about 10% (and in any event if incorporated, would reduce the radon flux and not increase it).

- The spreadsheet contains an error. Cell 'Diffi Co 2 unit conc (2)'!F46:F55 does not correctly multiply all correct parts of the term by the exponential.

  Arcadis has checked this calculation and appreciates the identification of a missing bracket. We have made a modification to the spreadsheet to show the impact of this change. The revised spreadsheet is attached. The overall dose including external gamma is updated to be 4 mrem/yr as opposed to 3 mrem/yr. In total the dose for 26 years of exposure results in 104 mrem or a risk of 0.5 in 10,000.

- Rather than calculate the buildup of radon daughter products within the home, the TFI risk assumed an equilibrium factor of 0.4. This may be a reasonable assumption, but was not well documented and may explain some of the difference in indoor radon dose between TFI's risk assessment and EPA's 1992 risk assessment.

  Arcadis: The 0.4 indoor equilibrium factor is a widely used default (notional value) for such calculations and is considered suitable for such generic risk calculations as postulated for the hypothetical and extremely unlikely reclaimer scenario[5].

The most consequential of these issues is the calculated radon flux through the foundation. Using more conservative, and arguably more realistic, estimates of the emanation factor and radon diffusion coefficients, the radon air concentration in the home could be several orders of magnitude higher than the 0.013 pCi/L (13 pCi/m^3) reported by Arcadis, and the reclaimer's inhalation dose more than an order of magnitude higher than the 1.8 mrem/yr reported for the reclaimer. The conceptual treatment of the

---

[4] Rogers V., Nielson K., Lehto M., Rodger H. Radon Generation and Transport Through Concrete Foundations. United States Environmental Protection Agency, Air and Energy Engineering Research Laboratory, EPA/600/SR-94/175. November 1994.

[5] NCRP 160, or UNSCEAR 2008 Annex E

slab and sub slab should generally be better explained. As stated above, the treatment of indoor radon for the reclaimer should be thoroughly justified wherever it departs from model default values and/or USEPA's 1992 risk assessment.

Arcadis: Further discussion of the basis for the assumed characteristics of the slab-on-grade home postulated for the hypothetical reclaimer is provided earlier in the memorandum and is based on Florida Building Code guidance as previously indicated.

As previously indicated, we suggest that the assumptions and model parameters used in the risk assessment are appropriate for the screening analysis of a reclaimer scenario.

As an aside, the average indoor radon level in US homes is about 1.4 pCi/L and the average (notional perhaps) outdoor level of radon is about 0.4 pCi/L. Thus, while we consider the calculations performed to be reasonable, even if the predicted indoor radon levels were to increase by a factor of say 10 to 0.013 pCi/L, the incremental levels would be in the variability of natural back indoor levels and for that matter within the natural variability of natural background radon levels outdoors.[6]

THE FERTILIZER INSTITUTE

Supplement to The October 11, 2019 TFI Phosphogypsum Reuse Petition: 2019 Radium-226 Results for U.S. Phosphogypsum Stacks

December 5, 2019

I. INTRODUCTION

On October 11, 2019, The Fertilizer Institute ("TFI") submitted a petition (hereinafter, the "Petition") to the U.S. Environmental Protection Agency ("EPA") requesting approval for the beneficial use of phosphogypsum ("PG") in road construction (*i.e.*, road base and/or concrete pavement), provided the PG contains no more than an average radioactivity concentration of 35 picocuries per gram ("pCi/g") of Radium-226 ("Ra-226").[1]

In conjunction with the submission of the Petition, TFI members agreed to perform radiological testing of PG. In particular, at EPA's request, two TFI members utilized EPA EML HASL-300 Method Ga-01-R (a 21-day method), entitled "Gamma Radioassay,"[2] for the sampling event. These members' PG stacks are located in Central Florida (where the highest Ra-226 levels would be expected), Louisiana, and the Western U.S. Because Northern Florida PG is used as a soil amendment and is regularly tested for Ra-226 using a different EPA-approved method, it is not included in this discussion.[3]

II. 2019 PG SAMPLING PROGRAM AND RESULTS

Nine stacks located in four states were tested. Ten samples were taken from each stack, for a total of 90 samples.[4] A summary of the results is as follows:

- The average Ra-226 concentration of all 90 samples is 18.6 pCi/g.
- Ra-226 concentrations in individual samples range from 6.3 pCi/g to 27.9 pCi/g.
- The average concentration in the Western U.S. is 15.8 pCi/g.
- As expected, the highest average PG stack result is from Central Florida (24.7 pCi/g), with the average of all six Central Florida stacks being 19.6 pCi/g.

---

[1] This level was proposed first and foremost with public safety in mind. The risk assessment analysis provided with the Petition demonstrates that PG containing Ra-226 levels up to 148 pCi/g is safe for road construction (*i.e.*, this concentration corresponds to EPA's regulatory risk of 3 in 10,000). *See* Arcadis, Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum at 5-2 (Oct. 2019) (hereinafter, the "Risk Assessment"). Further, an average Ra-226 concentration of 35 pCi/g represents the high-end of expected levels of Ra-226 in U.S. PG stacks (as discussed in Section III.B, below). PG containing <10 pCi/g has been used as an agricultural amendment for many years. This PG use is not the subject of the Petition.

[2] This method provides conservative Ra-226 values, reported by the laboratory as "Bismuth-214 (Ra-226)."

[3] PG used for agriculture purposes is tested for Ra-226 using EPA Method 903.1, entitled "Radium-226 in Drinking Water Radon Emanation Technique." Although a comparison cannot be made between the current sampling program and 2019 results from the three Northern Florida PG stacks tested using Method 903.1, for reference, the average 2019 sampling results for these three stacks (representing 30 samples) is 6.47 pCi/g.

[4] To preserve confidentiality, the results from the 2019 sampling program were blinded so the identity of the company and stack location were not disclosed.

III. ANALYSIS OF THE 2019 PG SAMPLING RESULTS

A. Comparison of the 2019 Results to The Risk Assessment Included With The Petition

The data provided above assist in the assessment of regulatory risks. The Risk Assessment submitted in support of the Petition demonstrates that PG containing an average of 148 pCi/g corresponds to the EPA safe Ra-226 risk goal of 3 in 10,000 (see Table 2 below, reprinted from the risk assessment submitted as part of the Petition).[5]

Table 2 – Radionuclide Risk Assessment from the Petition

Average Ra-226 in PG*** (pCi/g)	Exposure Duration Dose (Mrem)	Risk
10	40.7	0.20 per 10,000
20	81.5	0.41 per 10,000
27	110	0.55 per 10,000
30	122	0.61 per 10,000
35	143	0.71 per 10,000
40	163	0.81 per 10,000
50	204	1.02 per 10,000

*** Although we are not aware of any PG with average Ra-226 concentrations anywhere near 148 pCi/g, such PG could in principle be used for road construction and still achieve the EPA's safe level of a risk of 3 in 10,000.

[5] Risk Assessment at 5-2 (Table 5-1).

When viewed in light of the risk assessment, the 2019 PG sampling results demonstrate that the use of PG in the proposed application is consistent with EPA's view of a safe level of risk. For example:

- The average Ra-226 concentration from the 2019 stack sampling (18.6 pCi/g) is below the radioactivity concentration limit of 35 pCi/g proposed in the Petition, and well below the average Ra-226 concentration of 148 pCi/g that corresponds to an EPA safe risk level of 3 in 10,000.

- No individual concentration from the 2019 stack sampling (with concentrations ranging from 6.32 pCi/g to 27.9 pCi/g) exceeds 35 pCi/g.

- The average concentration of the six Central Florida PG stacks (19.6 pCi/g) as well as the individual PG stack averages (ranging from 15.01 to 24.69 pCi/g) are below the radioactivity concentration limit of 35 pCi/g proposed in the Petition, and well below the average Ra-226 concentration of 148 pCi/g that corresponds to an EPA safe risk level of 3 in 10,000.

- The average concentration in the Western U.S. (15.8 pCi/g) is below the radioactivity concentration limit of 35 pCi/g proposed in the Petition, and well below the average Ra-226 concentration of 148 pCi/g that corresponds to an EPA safe risk level of 3 in 10,000.

Thus, the 2019 sampling results demonstrate that the average of all 2019 stack samples and every individual sample result are well below the proposed radioactivity concentration limit of 35 pCi/g, and significantly below EPA's safe risk level of 148 pCi/g set forth in the Petition.

B. Comparison to Prior EPA PG Results

For context, in a 1992 Background Document,[6] EPA summarized data from a 1988 sampling of Central Florida PG stacks. The information from EPA's Background Document is reprinted below.

Table 3 – Reprint of EPA 1988 Central Florida PG Ra-226 Sampling Results

Phosphogypsum Stack	Mean Concentration (pCi/g dry)*	Concentration Range (pCi/g dry)
Gardinier	33± 2	31-37
W. R. Grace	30 ± 9	19-48
Royster	30 ± 11	16-49
Conserve	34 ± 18	23-81
Estech	25 ± 4	19-31

*Mean concentration with the standard deviation of samples from 10 locations on each stack.

Although the method of analysis from the 1988 sampling effort is unknown, the mean (average) results (ranging from 25 to 34 pCi/g) are higher than the average results from the 2019 sampling of Central Florida PG stacks (ranging from 15.01 to 24.69 pCi/g). However, both the 1988 and 2019 sampling results from Central Florida PG stacks demonstrate that the average concentrations are all below 35 pCi/g (the limit proposed in the Petition), and significantly below 148 pCi/g (the Ra-226 concentration corresponding to a 3 in 10,000 risk level).

[6] EPA, Potential Uses of Phosphogypsum and Associated Risk, Background Information Document, 402-R92-002 at 2-7 (Table 2-4) (May 1992).

C. Comparison to International PG Sampling Results

In addition to the 2019 and prior EPA sampling of U.S. PG stacks, data exist on the average Ra-226 concentrations in PG from 23 countries (including other data from U.S. stacks) that further confirm the 2019 U.S. PG stack data. According to published PG stack data, the Ra-226 concentrations range from 1 pCi/g (35 Bq/kg) to 38.4 pCi/g (1,420 Bq/kg)).[7] Representative information from the international review of PG Ra-226 data is set forth in Table 4.

Table 4 – NORM Radionuclide Activity in Phosphogypsum

Country	Ra-226 Concentration in becquerel/kilogram (Bq/kg) (converted to pCi/g)	Number of Samples	Reference
Australia	246 (6.7 pCi/g)	28	Beretka and Matthew (1985) Cooper (2005 and Msila et al. (2016)
Brazil	410 (11.1pCi/g)	268	De Conceicao and Bonotto (2006); Mazzilli and Saucia (1999) Santos (2006) Xhixha et al (2013)
Germany	305 (8.2 pCi/g)	2*	Trevisi et al. (2012)
Greece	440 (11.9 pCi/g)	31	Trevisi et al. (2012) and Turhan (2008)
Israel	747 (20.2 pCi/g)	1*	Gezer et al. (2012)
Jordan	378 (10.2 pCi/g)	16	Al-Jundi et al. (2008) Gezer et al. (2012)
Korea	618 (16.7 pCi/g)	1*	Gezer et al. (2012)
Morocco	1420 (38.4 pCi/g)	1*	Xhisha et al. (2013)
Spain	491 (13.3 pCi/g)	91	Trevisii et al. (2012)
The United Kingdom	1020 (27.6 pCi/g)	91	Trevisi et al. (2012)
United States	750 (20.3 pCi/g)	95	Hull and Brunett (1996); Roper et al. (2013)

* Sample too small to be statistically significant.

Even though the analytical methods used in the international compilation are not known, the average for the U.S. (20.3 pCi/g) corresponds closely with the 18.6 pCi/g average concentration across all nine stacks from the 2019 sampling program. These data (as well as the 2019 TFI data and the 1988 EPA PG data) illustrate

[7] See Chapter 6 at Table 6.16 in "Naturally Occurring Radioactive Materials in Construction" (2017). Chapter 6: "From raw materials to NORM by-products" is authored by T. Kovacs, et al., and is available from ScienceDirect, at https://www.sciencedirect.com/book/9780081020098/naturally-occurring-radioactive-materials-in-construction). Section 6.6.1.2 Radiological properties from Naturally Occurring Radioactive Materials in Construction, which contains Table 6.16, is also available online at https://www.sciencedirect.com/topics/engineering/phosphogypsum).

that the variation of individual Ra-226 concentrations in PG is relatively low, particularly compared to the safe level of 148 pCi/g.

All of the data support the view that it is very unlikely that any PG in U.S. stacks will exceed either (1) 148 pCi/g (EPA's PG safe level), or (2) 35 pCi/g (the level proposed in the Petition for reuse). Thus, no sampling should be required prior to shipping PG for road construction uses.

IV. CONCLUSION

Key highlights from this Supplement to TFI's Petition are set forth below:

- As expected, the highest levels of naturally occurring radiation are associated with the Central Florida samples.
- All of the data demonstrate that the individual, average, and medium Ra-226 concentrations from U.S. PG are below 35 pCi/g, and well below the 148 pCi/g level corresponding to EPA's safe level of 3 in 10,000.

These results verify that the Petition contains a reasonable maximum limit for the beneficial use of PG in U.S. road construction.

Economic Analysis of Phosphogypsum reuse

The Fertilizer Institute

Submitted by:

Policy Navigation Group

December 2019

EXECUTIVE SUMMARY

Policy Navigation Group (PNG) conducted this analysis on behalf of The Fertilizer Institute (TFI) to estimate the potential regulatory cost savings of changes that would expand the use of phosphogypsum (PG) to include road construction. This application is in use in Europe and elsewhere, but currently is precluded in the U.S. due to U.S. Environmental Protection Agency (EPA) regulatory restrictions. This section outlines the main steps we undertook to perform the analysis and summarizes the economic benefits of using PG for road construction.

Outline of Steps in Analysis

In the analysis that follows, we take these steps to estimate the potential cost savings of using PG for road construction:

> **Identify the costs to manage PG currently in stacks located at numerous sites.** These include the costs of land for the stacks, the costs to transport PG to the stacks, the costs of managing water at and preserving the physical stability of the stacks, and the costs to close the stacks.
>
> **Assess scenarios for PG reuse in road construction in the near future.** We assume that PG reuse will start modestly and grow over time. Given market uncertainty over the potential demand for PG, we estimate the savings for a lower-bound and an upper-bound scenario; any savings are expected to be within this range. Due to transportation costs and the availability of substitutes, we assume that the PG reuse market faces natural limits and largely is confined to locations relatively close to current plants and stacks.
>
> **Estimate the cost savings from PG reuse.** Companies can incur savings in PG management costs if they send PG to be reused (stack management savings from the regulatory reform). Since the stack management savings from the regulatory reform frees up the labor, capital, and physical land needed for PG stack management, in competitive markets some of these savings are passed through to the companies' customers and purchasers of PG for reuse. Ultimately the savings pass through to the state and local highway departments, companies' shareholders, companies' workers, farmers and other purchasers of fertilizer, and other households and firms.[1] For this reason, these cost savings are also the social benefits of the reform. They are also the deregulatory savings from an EPA action to allow reuse for road construction.

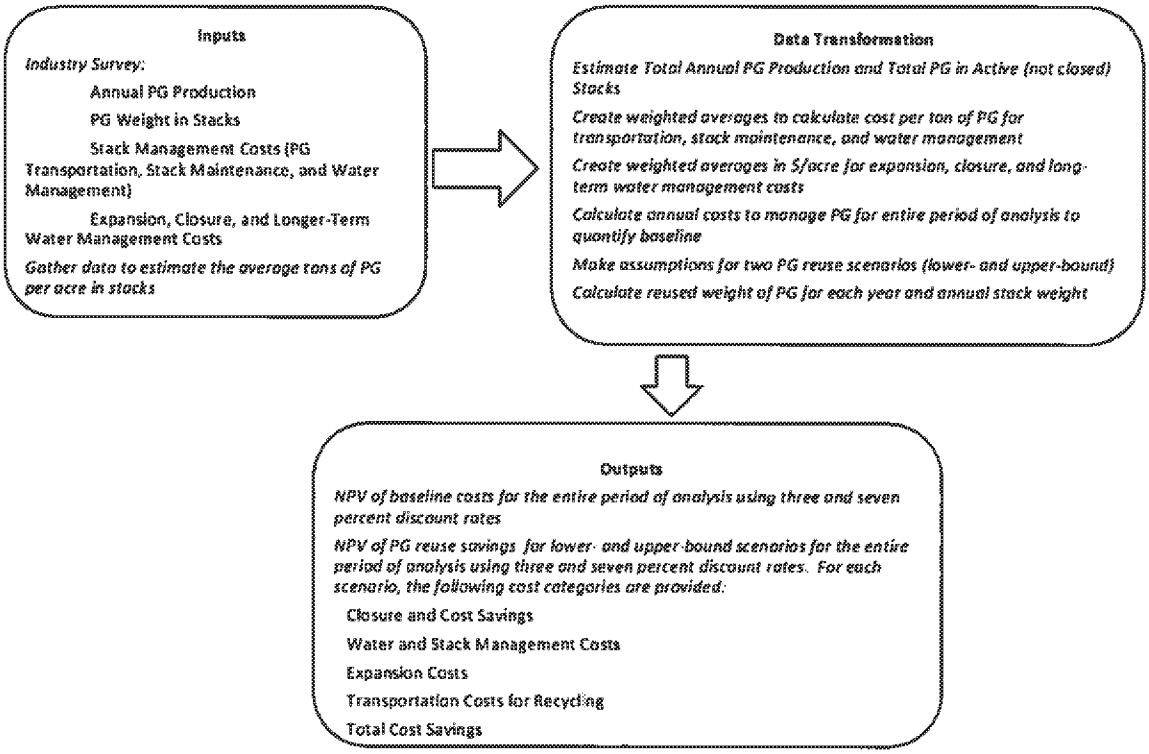
Figure ES-1 summarizes the key inputs used in the analysis and shows the data transformation and resulting outputs.

---

[1] In this analysis, we only consider the direct economic impact of the reform. There will be indirect and induced economic impact of the reform as fertilizer customers have lower input costs and can gain market share from imports and as workers spend their greater compensation on consumer goods and services. These gains then induce additional economic impact such as higher spending by vendors to the fertilizer purchaser and the workers.

ED_005285_00000749-00002

Figure ES-1: Diagram Summarizing Analytical Approach for Project[2]



Summary of the Regulatory Savings

The analysis produced by taking the steps above provides a clear picture of the cost savings of using PG for road construction. Table ES-1 presents the baseline costs to manage PG from 2020-2042, which range from $1.3 billion to $0.88 billion using three and seven percent annual discount rates. Table ES-2 summarizes the cost savings from PG reuse for the two reuse scenarios; it shows that the total net present value (NPV) savings range from $37 million to $52 million for the lower-bound scenario and from $110 million to $160 million for the upper-bound scenario, using discount rates of seven and three percent, respectively.[3] We use three and seven percent discount rates to calculate the results from this analysis, as directed by U.S. Office of Management and Budget Circular A-4.

[2] We use three and seven percent discount rates to calculate the results from this analysis, as directed by the U.S. Office of Management and Budget's Circular A-4.

[3] The results presented in this analysis are rounded to two significant figures. Due to rounding, total values in the tables may not sum.

ED_005285_00000749-00003

Table ES-1: Net Present Value (NPV) of Baseline Costs to Manage PG

CATEGORY	NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Baseline Costs	1,300	880

Table ES-2: Net Present Value (NPV) of Cost Savings from PG Reuse

COST CATEGORY[4]	LOWER-BOUND SCENARIO NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	LOWER-BOUND SCENARIO NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)	UPPER-BOUND SCENARIO NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	UPPER-BOUND SCENARIO NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Closure Cost Savings	11	11	33	32
Water and Stack Management Costs	22	13	65	37
Expansion Costs	19	13	57	38
Total Cost Savings	52	37	160	110

In summary, expanding the use of PG in road construction is expected to result in savings not only to PG producers, but also to numerous users of PG and workers, shareholders, and customers of fertilizer firms.[5]

[4] Transportation savings are omitted from the results shown in this table as they amount to zero dollars. Transportation cost from the stack to the construction site is not included because it is assumed that the customer would pay for this transportation as part of the road construction cost.

[5] Savings to users of PG, workers, shareholders, and customers of fertilizer firms are not evaluated in this economic analysis.

INTRODUCTION

Policy Navigation Group (PNG) conducted this analysis on behalf of The Fertilizer Institute (TFI) to estimate the potential regulatory cost savings of using phosphogypsum (PG) for road construction, an application currently in use in Europe and elsewhere. This section provides a summary of the industry, followed by a description of PG, its production in the U.S., and U.S. Environmental Protection Agency (EPA) PG requirements. It then touches upon PG reuse options and scenarios before concluding with a description of how the remainder of the report is organized.

Summary of Industry

Phosphate rock is predominantly used to produce phosphoric acid, which is primarily used to manufacture fertilizer. The U.S. was previously the largest producer of phosphate rock and leading exporter of phosphate fertilizer, until China increased its production in 2011 and surpassed the U.S. as lead world exporter in 2014.[6] Currently, the U.S. is the second-largest consumer of phosphate rock (consuming 29 million metric tons (MT)) and the second-largest producer of phosphoric acid (producing 14 million MT).[7] Domestically, phosphate rock ore is mined primarily by five firms in four states — with 80 percent of the mining occurring in Florida and North Carolina — to produce approximately 27.1 million tons of marketable product.[8] After being mined in open-pit mines, phosphate rocks are treated, washed, and dried in rotary kilns.[9] The ore is then finely ground and converted into a soluble form through either a wet or dry process. In the U.S., facilities exclusively use a wet process that digests the phosphate rock in a reaction vessel with sulfuric acid, producing both phosphoric acid and a largely calcium sulfate byproduct known as PG.

Total worldwide production of PG is estimated between 100-280 mega tons per year.[10] About 85 percent of world PG production is discarded or stored. The remaining 15 percent of worldwide production is reused as soil amendment, agricultural fertilizer, and set controller for cement and building materials worldwide.

Around the world, PG is used in a range of applications, including:[11]

- In fertilizer for agricultural soils;
- In backfill and road-base material for roadway and parking lot construction;
- As an additive to concrete and concrete blocks;

- In wallboards;
- In mine reclamation; and
- In the recovery of sulfur.

Prior to the 1992 EPA restrictions on its widespread reuse, PG was critical to the peanut industry as a soil amendment valued for its fertilizer properties across Georgia, North Carolina, Virginia, and Alabama, and on farms across the southeast that grow tobacco, corn, small grain, and sugar cane.[12] As a large peanut producer, Georgia was the largest PG consumer. States such as California also used PG for soils growing citrus, almonds, vegetables, and tomatoes. In these and other locations, PG was widely used, since it had been shown to be a beneficial source of sulfur in improving crop yields.

Description of Phosphogypsum

PG byproduct is filtered from the phosphoric acid and transferred as a water slurry to be stored in open-air areas called PG stacks. The slurry is pumped atop the stack, where an engineered "gypsum stack and pond" is formed. Water impounded from PG stacks is reused in the overall wetting process. Closing PG stacks involves complex engineering, including placing high-density polyethylene liners as caps to prevent rainwater from infiltrating and reduce stack water from percolating out from the bottom of the stacks.[13]

Reuse Options and Scenarios

Other countries, most notably Japan and some nations in Europe, have and currently reuse some PG for specified uses that have included road base material, cement, wallboard, and other building materials.[14]

Road Base

Prior to EPA restrictions on its use in 1992, PG was mixed with ash, sand, gravel, or cement, and was used as a base for roads, parking lots, and storage areas to help control setting times, counteract shrinkages, strengthen cement products, and create resistance to sulfate etching.[15] Numerous publications are available detailing these uses. The following are some examples of how PG was used in Texas, Florida, and North Carolina:[16]

- In Pasadena, Texas, PG was mixed with fly ash and cement for road base at five sections of city streets in La Porte, Texas.
- In Polk County, Florida, PG was mixed with granular sand to construct 2.4 kilometers of road base, surfaced with asphalt.

[15] U.S. Environmental Protection Agency.

[16] U.S. Environmental Protection Agency.

ED_005285_00000749-00009

- In Columbia County, Florida, two miles of road base was constructed with 100 percent dehydrated PG and varying mix ratios of PG and sand. The road base was also surfaced with asphalt.
- In North Carolina, PG was commercially used as a fill and sub-base for roads in swampy areas.
- In Bartow, Florida, the Florida Institute of Phosphate Research used a mixture of PG and concrete to pave two thousand yards of driveway and parking areas.

Cement and Concrete Aggregate

PG also has been used to manufacture building materials, including concrete and cement aggregates, particularly outside the U.S.[17] Additionally, it can be used more extensively in building materials, including cement, wallboard, ferrocement panels, plasterboard panels, partition blocks, plaster, tiles, artificial stone, and glass ceramics.[18]

Several studies have demonstrated that PG can help prolong concrete setting times.[19] The increased setting time supports long-term concrete strength. Incremental initial and final setting times increase with increasing PG content. Using PG as a retarder agent is particularly beneficial in civil engineering work involving casting in hot weather, casting retaining deep walls, and casting mass concrete and repair elements, for example.[20]

Including PG in cement also has the benefit of reducing density, increasing chemical resistance, increasing free resistance, and increasing fire resistance.[21] As such, PG has the potential to be used as a partial substitute for materials aggregate in concrete.

Organization of the Report

The rest of the report discusses current PG management costs and incurred savings from PG reuse, showing how we developed scenarios for PG reuse and estimated the cost savings for these scenarios. Since the regulatory change frees up the labor, capital, and physical land needed for PG stack management, these savings are also the social benefits of the regulatory reform.

CURRENT PG MANAGEMENT COSTS AND COST SAVINGS FROM PG REUSE

Introduction and Methodology Overview

This section provides an overview of current PG production and PG stored in stacks; details and quantifies the current costs of PG management; describes and quantifies the potential short- and long-term cost savings if a percentage of currently produced PG is reused for road construction; provides baseline and PG reuse scenarios to illustrate several key points; and presents the variables, assumptions, and methodology used in all the above.

A survey was conducted with members of TFI in July 2019. The survey included questions on current PG production; weight of PG stored in active stacks; and costs to transport, manage, expand, and close stacks. The survey was conducted, compiled and summarized by an independent party who removed identifying information before data was provided to PNG for analysis. The survey questions are provided in Appendix 1.

Using the survey information, we estimate averages for current production, average weight of PG stored in active stacks, and costs. With these estimates, we calculate the current costs of managing PG — the baseline costs. Then, we create two scenarios (lower- and upper-bound) to estimate the cost savings if a percentage of the PG produced is beneficially reused.

The timeline of the analysis is from 2020 to 2042. All future values are discounted using a three and seven percent discount rate and presented in 2019 dollars.[22] The values in the tables are rounded to two significant digits. Therefore, the totals shown in some tables may not sum exactly. We only consider active PG stacks for this analysis, as according to information received from the industry, it is unlikely that PG from closed stacks would enter the reuse market.

PG Production and Annual Growth Rate

Survey participants provided annual PG production data (in tons per year) for 2016, 2017, and 2018 for nine active stacks. Data was provided by the largest PG producers in the U.S., but it does not include all active stacks and PG producers in the country. To account for variability across stack data (both, on annual basis and by stack), we calculate weighted averages. To calculate the weighted annual production rate, we estimate the average growth (in tons) for each stack from 2016 to 2017 and from 2017 to 2018. Then, we estimate the corresponding weighted average growth rate for each period (from 2016 to 2017 and 2017 to 2018). We derive industry representative weighted averages by weighing each stack's size by its proportion of the sum of the size for all the stacks in the survey.

To estimate the annual production of PG available for reuse, we calculate the weighted average across all the active stacks. For this estimate, we quantify the multi-year average per active stack (from 2016 to 2018) and then the weight of the multi-year average per stack in relation to all the active stacks. This gives a weighted average annual production of PG of 5.1

[22] U.S. Department of Labor, Bureau of Labor Statistics, "CPI Inflation Calculator."

ED_005285_00000749-00011

million tons. We multiply this value by nine stacks to obtain a weighted annual total U.S. production of 46 million tons of PG.

For this report, we assume that PG production in the U.S. will not experience growth in the timeline of the analysis — that it will remain at the same level as in the baseline. We make this assumption because information received from the industry for this analysis forecasts no growth. Furthermore, the survey data spans only a three-year period and varies by company and year, rendering it difficult to determine any long-term trend in terms of growth. We note that this assumption is in line with market reports from Europe, which show near-zero growth for PG production between 2012 and 2017.[23]

Table 1 summarizes the PG production data used for the analysis.

Table 1: PG Production

ITEM	AMOUNT
Weighted Average of Production, Per Year, Per Stack	5,100,000 tons
Total Annual Production of PG	46,000,000 tons

PG Stored in Stacks

For the nine active stacks discussed in the previous subsection, we received the approximate amount of PG stored in each. For eight of the nine stacks, the weight was provided in tons. For one of the stacks, we were provided the volume in cubic yards, which we converted into tons using a density factor of 1.9 tons per cubic yard.[24]

The surveyed companies also provided information for inactive stacks, as PG from inactive stacks may be used.

Using the survey information, we add the total weight in both active and inactive stacks. Additionally, we calculate the weighted average tons for both types of stacks by creating weights per stack (that is, how much each stack represents of the total in the corresponding category). These weights are further used to estimate the average costs per ton (see subsection below).

Figure 1: Projected New PG Production and PG in Stacks[25]

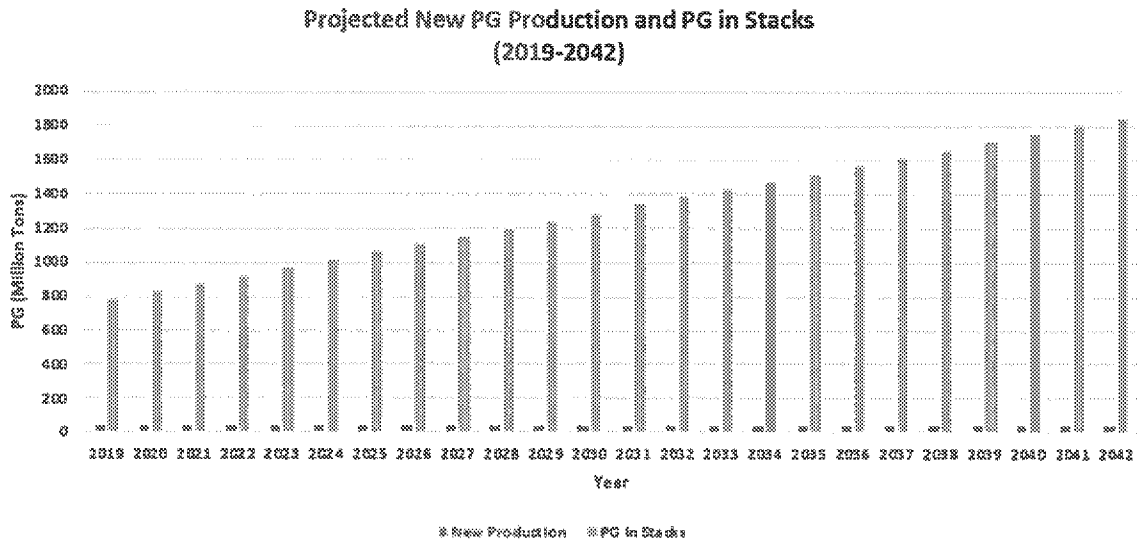

Table 2 summarizes the PG stored in stacks and Figure 1 shows both the PG in stacks and the projected new production of PG. While the period of analysis is 2020-2042, Figure 1 includes data for 2019, as the PG in stack value for 2020 must include the weight for 2019.

Table 2: PG in Stacks

ITEM	ACTIVE STACKS	INACTIVE STACKS	TOTAL
Total PG Stored (million tons)	517	217	734
Weighted Average Per Stack (million tons)	69	65	N/A

Costs to Manage PG

In response to the survey, companies provided annual costs per stack for the following categories[26]:

- Transportation costs — costs to transport PG from the plant to the stacks
- Stack maintenance costs — labor, monitoring, inspection, and reporting costs
- Water management costs — costs for water balancing and water treatment

[25] Figure 1 reflects the current baseline and does not show the PG reuse scenarios discussed later in the analysis.

[26] The cost information was provided by stack and was not tied to PG production levels.

We then use the weights calculated for PG production and PG stored in stacks (see previous subsections) and apply those to the survey data's cost per stack. For the transportation costs, we use the weights for PG production, as transportation costs are incurred in transporting PG from the plant to the stacks; once the PG is in place at the stack, no additional transportation costs are assumed to be incurred. For stack maintenance and water management costs, we use the weights corresponding to PG stored in stacks and apply them to the whole amount of PG stored in a stack. Then, we calculate the weighted average cost per category. To do this, we multiply the corresponding weight by the cost per year per stack, add those products, and divide the resulting sum by the sum of the weights used. Finally, we obtain the average cost per ton by dividing the weighted average by the number of tons per cost category.

The volume of water generated and treated (the water management volume) can be affected by factors such as weather conditions, the manufacturing process, and the age of the PG. The major climate consideration would be variability in precipitation among different geographic regions. While water management volumes would decrease over time due to reduction in size and number of PG stacks, it would not completely disappear. As with all new sustainability strategies, innovation and synergies may lead to additional water management reductions as yet to be determined.

Thus, in practice, the stack water generation and treatment volumes can vary significantly by the location and by the age of the stack. While we asked respondents for typical, current values for water management costs, we are unaware if respondents provided data that represents average climate conditions and PG aging.

Table 3 provides the weight of PG in active stacks, the weighted average costs and the cost per ton for the three cost categories.

Table 3: Weight of PG in Active Stacks and Costs

ITEM	TRANSPORTATION COSTS	STACK MAINTENANCE COSTS	WATER MANAGEMENT COSTS
Weighted Average ($ millions)	7.2	6.8	7.4
Total Tons of PG in Category (million tons)	8.3	570	380
Average Cost Per Ton ($)[27]	0.87	0.012	0.02

[27] Average cost per ton is obtained by dividing the weighted average by total tons of PG. For example, for transportation costs 7.2/8.3=$0.87. Note that values in the table are rounded to two significant figures as noted earlier in the analysis. As a result, total values in table may not sum exactly.

ED_005285_00000749-00014

Other Stack-Related Costs

Survey participants indicated that, in addition to transportation, water management, and stack maintenance costs, there are other long-term costs associated with PG stacks — stack closure costs, water inventory costs, and stack expansion costs. These costs are expected to be incurred in the next five years (between 2020 and 2024).

To avoid providing identifiable information, the surveyed companies provided costs for those long-term categories in dollars per acre of PG stack. In some instances, they provided a lower- and upper-bound estimate for the category. Also, some companies reported zero costs for the category or reported them as part of another category. For this analysis, we create upper- and lower-bound estimates per category, then calculate the middle-point value. Table 4 outlines these costs.

Table 4: Long-Term Costs of PG Management

ITEM	STACK CLOSURE COSTS	WATER INVENTORY COSTS	STACK EXPANSION COSTS	TOTAL	UNIT
Average — Lower Bound	91,000	23,000	220,000	330,000	$/acre
Average — Upper Bound	100,000		240,000	360,000	$/acre
Total Average	96,000	23,000	230,000	350,000	$/acre

Cost Summary

Table 5 summarizes the cost savings due to PG reuse. The most significant savings occur from deferring stack closure and expansion, which together represent almost $350,000 per acre of PG. Since one stack can contain more than 70 million tons of PG, the cost savings of reusing PG are significant.

ED_005285_00000749-00015

Table 5: Short- and Long-Term Costs of PG Management

ITEM	COST	COST TYPE	UNIT
Transportation Costs	0.87	Short-term	$/ton
Stack Maintenance Costs	0.01	Short-term	$/ton
Water Management Costs	0.02	Short-term	$/ton
Stack Closure Costs (includes water inventory costs)	120,000	Long-term	$/acre
Stack Expansion Costs	230,000	Long-term	$/acre

Cost Savings from PG Reuse Scenarios

Baseline Scenario

In this scenario, we quantify the current costs of managing PG at phosphoric acid plants. As outlined in Table 1, the weighted annual PG production is approximately 46 million tons. Figure 1 outlines the total amount of PG expected to be produced per year from 2020 to 2042. It also presents the amount of PG expected to be stored in stacks during that same period. Given the current regulatory restrictions on using PG, this scenario assumes that all new PG produced is put into stacks.

To estimate the costs for the baseline scenario, we first multiply the weighted annual production of PG by the transportation costs per ton ($0.87). We then multiply the weight of PG stacked by the sum of stack maintenance and water management costs per ton of PG ($0.03). Finally, we add the transportation, stack maintenance, and water management costs for the entire period and calculate the net present value (NPV) using discount rates of three and seven percent.

PG Reuse Scenarios

Lower-Bound Scenario

In this scenario, we assume that a percentage of PG produced annually is reused. When PG is reused rather than put into stacks, PG producers incur savings in water management costs, stack maintenance costs, and long-term savings for the amount of PG reused; the only costs they incur are those associated with transport of PG from the facility to the construction site. The NPV of these cost savings minus the transportation costs to the construction site (at discount rates of three and seven percent) are the results for this scenario.

This scenario assumes that five percent of current PG production is reused in each year in 2020 and 2021, 7.5 percent is reused each year in 2022 and 2023, and 10 percent is reused

ED_005285_00000749-00016

in 2024 (see Table 9). Between 2025-2042, the assumed reuse percentage remains at 10 percent. We arrive at this representative reuse scenario by assuming that the PG reuse market will start slowly due to the availability of competing products that already have market share and may be sold through longer-term contracts. Additionally, since PG has been off the market for almost 20 years, this assumption accounts for the idea that it may take PG sellers some time to convince potential customers of PG's beneficial qualities. With these assumptions in place, we calculate water management, and stack maintenance savings by multiplying the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03 (see Table 6).[28]

Upper-Bound Scenario

In this scenario, we assume that PG suppliers will offer favorable pricing relative to competing products, effectively promoting greater PG reuse that grows robustly over time. Specifically, we assume that 10 percent of current PG production is reused in 2020, 15 percent is reused in 2021, 20 percent is reused in 2022, 25 percent is reused in 2023, and 30 percent is reused from 2024 (see Table 6). As in the lower-bound scenario, we arrive at this representative reuse scenario by assuming that the PG reuse market will start slowly due to the availability of competing products that already have market share and may be sold through longer-term contracts, and that it may take PG sellers some time to convince potential customers of PG's beneficial qualities. With these assumptions in place, we calculate water management, and stack maintenance savings by multiplying the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03 (see Table 6).

[28] Water management and stack maintenance savings are recurrent annual costs. Therefore, they are calculated over the sum of PG reused in a given year plus PG reused in the previous years. For example, for the upper-bound scenario in 2022, water management and stack maintenance savings are calculated over 20.7 tons (sum of amount reused from 2020-2022).

ED_005285_00000749-00018

Comparison of Reuse Scenario versus Current Demand for Road Construction

We compare this reuse scenario to the size of local markets as one measure of the reasonableness of the scenario. To validate that our assumptions on PG reuse are feasible given the overall size of the road aggregate market, we contacted the Florida Department of Transportation. We selected Florida as a representative construction market since a majority of the nation's PG is generated in Florida.

Due to the high cost of transporting PG to be used in road construction, we consider that the potential demand for PG is limited to within one day's hauling of the production location, or approximately 200 miles. Both the lower and upper bound scenarios of PG reuse are well within Florida's projected future demand for aggregate for road construction.

Stack Closure Costs

We assume that by reusing a percentage of current production, PG producers will be able to defer stack closure costs. Thus, less PG would need to be stored in stacks, and current stack capacity would last longer. However, it is difficult to predict the number of stacks that may be closed — or expanded — in the period of analysis (and thus estimate the potential cost savings from those deferred stack closures). We believe this to be the case based on insights provided by survey respondents, which suggest that stack closure and stack expansion decisions require long-term strategic planning and are subject to company-specific PG production forecasts and stack capacity.

Recognizing the limitations of generalizing from company-specific conditions to a industry-representative average, in this analysis, we start by assuming that stack closure costs are deferred until 2039 for both the lower- and upper-bound scenarios. The assumption that a stack is closed in 2039 is consistent with historic stack closure reports, as stacks are generally closed after reaching a certain acreage. The purpose of this estimate is to show the potential savings that could arise from deferring stack closure due to PG reuse. For these estimates, the closure cost per acre of PG corresponds to the sum of the water inventory management and stack closure costs ($120,000). Closure occurs in 2039, but the period of analysis covers years until 2042 to allow for the completion of active stack closure activities.

The weight of PG in the survey is provided in tons, while the long-term costs are provided in dollars per acre. Therefore, we next need to estimate how much PG is generally found in one acre. For this estimate, we use a dataset with stack data for Florida.[29] This dataset has information on stack area and length. We assume that all stacks in the Florida dataset are 100 meters in height, have a rectangular base, and have a side slope of 1:3. To estimate the stack width, we divide area by length. Then, we calculate the volume per stack and multiply that volume by an assumed density of PG of 2.3 g/cm^3.[30] (The approach to estimate the stack

[29] State of Florida, "Florida Gypsumstacks."

[30] U.S. EPA, Region 4, Superfund Division, "Engineering Evaluation/Cost Analysis: Closure of the East Gypsum Stack and North Ponds, Mississippi Phosphates Corporation Site, Pascagoula, Jackson County, Mississippi."

ED_005285_00000749-00019

volume was derived from EPA and Florida Department of Environmental Protection sources.[31]) Finally, since the Florida dataset uses data in metric units, we convert square meters into acres. Thus, we conclude that one acre contains approximately 850,000 tons of PG. We then divide the total tons of PG reused in 2039 for the lower- and upper-bound estimates by 850,000 to obtain the equivalent number of acres, multiply it by the actual cost per acre ($120,000), and present the NPV using three and seven percent discount rates.

In this report, based on the estimated reused PG from 2020-2039, we assume that a PG stack of 97 acres is closed in 2039 for the lower-bound scenario and a PG stack of 290 acres is closed in 2039 for the upper-bound scenario.

Stack Expansion Costs

To estimate the potential cost savings from stack expansion, we first divide the weight of PG reused per year by 850,000 to convert it into acres. We then multiply the resulting quotient by $230,000, which is the cost to expand one acre. Finally, we discount the costs using three and seven percent rates.

Stack Maintenance and Water Management Costs

To estimate the potential cost savings from stack maintenance and water management, we first multiply the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03. We then calculate the NPV for the entire period of analysis using three and seven percent discount rates.

Transportation Costs to Reuse Location

We assume that PG transportation costs are essentially the same as the cost of transporting alternative materials; therefore, from a social cost perspective, there is no marginal savings by transporting PG or another aggregate. This leads to the conclusion that there are no potential benefits related to savings from transportation costs. Thus, transportation costs are not shown in Table 9 considering that they are zero.

Table 7 provides the key assumptions for PG reuse used in the analysis.

[31] Florida Department of Environmental Protection, "Florida Gypsumstacks, Phosphogypsum Stack System Layer."; U.S. Environmental Protection Agency, "National Emission Standards for Hazardous Air Pollutants; National Emissions Standards for Radon Emissions from Phosphogypsum Stacks; 40 CFR Part 61," 13-19; and Appendix B.

Table 7: Key Assumptions for PG Reuse Scenario

ITEM	LOWER-BOUND SCENARIO	UPPER-BOUND SCENARIO
PG reused in 2020	5% of annual production	10% of annual production
PG reused in 2021	5% of annual production	15% of annual production
PG reused in 2022	7.5% of annual production	20% of annual production
PG reused in 2023	7.5% of annual production	25% of annual production
PG reused in 2024	10% of annual production	30% of annual production
Year in which stack closure occurs	2039	2039
Conversion rate for PG (tons into acres)	850,000	850,000

Results of Cost Savings from PG Reuse

Table 8 shows the total NPV of baseline costs associated with managing PG stacks, which range between $0.88 billion and $1.3 billion at seven and three percent discount rates, respectively.

Table 8: NPV of Baseline Costs to Manage PG

CATEGORY	NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Baseline Costs	1,300	880

The total NPV of cost savings between 2020-2042 is presented in Table 9. It shows savings associated with PG reuse ranging between $37 million and $52 million for the lower-bound scenario and $110 million and $160 million for the upper-bound scenario, using seven and three percent discount rates, respectively. It also presents the estimated cost savings for stack closure, water and maintenance management, expansion, and transportation costs. The largest savings result from the deferred stack expansion costs, with the second-largest savings a result of deferred stack closures.

ED_005285_00000749-00021

Table 9: NPV of Cost Savings from PG Reuse

Total Cost Savings	52	37	160	110

Executive Order 13771 Deregulatory Savings

Under E.O. 13771, EPA's action to allow PG to be reused as a road construction material would constitute a deregulatory action and would generate savings that could help EPA achieve its regulatory allocation.

Assuming that EPA either changes its existing regulation to allow a regulatory exemption for PG reuse in road construction or gives a one-time, broad approval of a petition for road construction reuse, EPA's action would constitute a deregulatory action under E.O. 13771. The Office of Management Budget's implementing memorandum for E.O. 13771 draws the distinction between routine regulatory actions and one-time actions that produce on-going savings. Agency actions that require regular agency approvals - e.g., quotas, permits - are not deregulatory actions under E.O. 13771. However, if EPA's approval of PG petitions does not require further approvals, is not conditioned on satisfying reporting requirements, and is broadly applicable to PG producers, it would likely qualify as a deregulatory action. EPA then could count it as part of meeting E.O. 13771's ratio of one deregulatory action for every two regulatory actions.

The action would also generate deregulatory savings. Under E.O. 13771, agencies are granted a regulatory allocation for each fiscal year.[33] The regulatory costs of significant economic regulatory actions and the deregulatory savings must add up to less than the agency's allocation. Agencies must align the savings and costs in the same fiscal year; in this case, the deregulatory savings from allowing PG reuse occur in future years. Table 10 gives the

[32] Transportation costs are omitted from the table as they are zero. Potential revenue obtained from selling PG is not estimated in this report.
[33] "Executive Order 13771 of January 30, 2017, Reducing Regulation and Controlling Regulatory Costs."

ED_005285_00000749-00022

estimated annual savings for the next five years, an illustrative period to demonstrate how savings increase in the near-term before reaching a relatively constant value.

Table 10: Estimated Cost Savings from 2021-2025

TOTAL COST SAVINGS (IN MILLIONS $)	2021	2022	2023	2024	2025
At 3 and 7 Percent Discount Rate	1.1-3.2	1.7-4.5	1.8-5.8	2.4-7.2	2.6-7.7
At 7 Percent Discount Rate	1.1-3.2	1.7-4.5	1.8-5.8	2.4-7.1	2.6-7.6

Summary

In summary, the analysis shows that the potential regulatory cost savings of changes that would allow the reuse of PG ranges between $37 million and $160 million. These results represent the NPV of savings for the period of analysis (2020-2042). These results strongly support the reuse of PG for beneficial applications such as road construction in the U.S. — applications already permitted and used in Europe and elsewhere. Additionally, they support the idea that using PG for road construction offers the possibility of significant savings not only to PG producers, but also to state transportation agencies to the extent they replace a percentage of the aggregates currently used for road construction with PG.

Hi Jon,

I wanted to follow up on this email from Monday. Did this response get sent out?

Thanks!
Stefanie

Thank you Tony.

Jon, I agree with Tony that the response was written well. Could you please coordinate a technical approval from Tom or Dan and then bcc me on the official response? I will make sure that we keep a record of this response along with our other files.

Thank you,
Stefanie

Subject: RE: Request for additional information

It's really not a cold call. Jon is listed in the Federal Register as the contact, and as such, can reply directly to the questioner. This is a technical question, so there's no need to involve OPA if the press is not involved.

I think Jon answered the question very well, but given the interest in the topic, Jess and I would recommend that Dan S. or Tom approve all replies before they are sent. Also, we should keep a file of these inquiries and our replies.

Thanks!

Tony

Tony,

How do we typically handle "cold calls" or in the case below, cold emails ☺ Jon received an email from what seems to be a member of the public. No other affiliation is noted. Is this something that Jon, or Radiation.Questions@epa.gov can reply to, or do we need to loop in OPA?

Thank you,
Stefanie

Subject: FW: Request for additional information

Stef, here is the question and my proposed answer.

Thank you for reaching out with your questions.

The resolution of the groundwater issues raised by SC&A in included in the EPA summary document, "Review of the Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum Prepared for the Fertilizer Institute," in the Section Offsite Individual and Water Pathways, which begins on page 18. For groundwater transport, the SC&A analysis assumed that the phosphogypsum was uncovered by pavement and therefore fully open to infiltration by precipitation, which is not expected to occur, and the resultant risks did not exceed the EPA's threshold for approval. For the crayfish scenario, in order for risk thresholds to be exceeded, surface water must already be contaminated by the radionuclides found in phosphogypsum, which is also not expected to occur.

Rather than require TFI to perform additional analyses, the EPA included conditions which will prevent or minimize contact between phosphogypsum and water. As noted in the EPA summary, "TFI has proposed a generic road design in which phosphogypsum is fully covered by pavement and is therefore protected from infiltration. Additionally, the phosphogypsum is contained in a single, 25 cm layer, which presumably keeps phosphogypsum out of contact with groundwater under typical conditions. As long as these aspects of the generic design are maintained, it is reasonable to expect that the water pathway will not result in unacceptable radiological risks. Should the design change in a way that creates additional exposure of phosphogypsum to water, then this pathway warrants a more involved analysis."

The final approval limits phosphogypsum to a single layer and requires that all phosphogypsum be covered by pavement. With these restrictions in place, the EPA did not require TFI to perform additional analysis of the water pathways. As noted in the EPA's summary, should a different design be proposed, these analyses may be needed at that time.

Subject: Request for additional information

To: Jonathan P. Walsh, walsh.jonathan@epa.gov

Good Evening Mr. Walsh,
On October 20, 2020, EPA published a notice in the Federal Register regarding EPA's "Approval of the Request for Other Use of Phosphogypsum by the Fertilizer Institute". One of the technical documents supporting this approval, posted on EPA's webpage dedicated to this issue, is titled "Technical Review of The Fertilizer Institute Risk Assessment for Additional Use of Phosphogypsum in Road Base," dated June 10, 2020. Multiple times in this review document, it is suggested that The Fertilizer Institute (TFI) provide further information and/or analysis on specific issues. For example, on page 46, it is recommended that TFI be required to further explore both the groundwater and ingestion of crayfish exposure pathways; on page 45, it is recommended that TFI be requested to revise its reclaimer radon exposure dose calculations, and it is stated that "TFI's evaluation of the Nearest Resident exposure pathways needs to be revised." I am wondering if EPA ever requested these revisions, if TFI ever provided them, and if so, where I might access documentation of those revisions? I have explored all the links included on the EPA's "Approval of Other Uses of Phosphogypsum: Supporting Documents" web page and have been unsuccessful in identifying any such document. Thank you in advance for your time and consideration.

Respectfully,
Audrey Ford

Lee and Jon,

Good morning. I hope this finds you both well.

Attached is a updated version of the PG petition, response to the EPA questions on the risk assessment posed in January, response to the questions on the reclaimer scenario, and other assorted supporting appendices, some of which you have already seen. Not attached are Appendices 1 and 2, which accompanied the submittal in October 2018. I would be happy to resend these to your attention, if so desired.

Please confirm that you received these files (9 in all).

I will reach out early next week to discuss next steps in the petition review process and the potential need for a conference call.

Regards,
Andy

Subject: RE: Request for additional information

Yes, I responded and did not hear back.
Strangely, I attempted to archive the response that I sent, and can't readily locate it. I will add that as a personal to-do item.

Jon

Subject: FW: Request for additional information

Hi Jon,

I wanted to follow up on this email from Monday. Did this response get sent out?

Thanks!
Stefanie

Thank you Tony.

Jon, I agree with Tony that the response was written well. Could you please coordinate a technical approval from Tom or Dan and then bcc me on the official response? I will make sure that we keep a record of this response along with our other files.

Thank you,
Stefanie

Subject: RE: Request for additional information

It's really not a cold call. Jon is listed in the Federal Register as the contact, and as such, can reply directly to the questioner. This is a technical question, so there's no need to involve OPA if the press is not involved.

I think Jon answered the question very well, but given the interest in the topic, Jess and I would recommend that Dan S. or Tom approve all replies before they are sent. Also, we should keep a file of these inquiries and our replies.

Thanks!

Tony

Tony,

How do we typically handle "cold calls" or in the case below, cold emails ☺ Jon received an email from what seems to be a member of the public. No other affiliation is noted. Is this something that Jon, or Radiation.Questions@epa.gov can reply to, or do we need to loop in OPA?

Thank you,
Stefanie

Stef, here is the question and my proposed answer.

Thank you for reaching out with your questions.

Ex. 5 Deliberative Process (DP)

From: Audrey Ford <audreytford@gmail.com>
Sent: Monday, November 23, 2020 8:21 PM
To: Walsh, Jonathan <Walsh.Jonathan@epa.gov>
Subject: Request for additional information

To: Jonathan P. Walsh, walsh.jonathan@epa.gov

Good Evening Mr. Walsh,
On October 20, 2020, EPA published a notice in the Federal Register regarding EPA's "Approval of the Request for Other Use of Phosphogypsum by the Fertilizer Institute". One of the technical documents supporting this approval, posted on EPA's webpage dedicated to this issue, is titled "Technical Review of The Fertilizer Institute Risk Assessment for Additional Use of Phosphogypsum in Road Base," dated June 10, 2020. Multiple times in this review document, it is suggested that The Fertilizer Institute (TFI) provide further information and/or analysis on specific issues. For example, on page 46, it is recommended that TFI be required to further explore both the groundwater and ingestion of crayfish exposure pathways; on page 45, it is recommended that TFI be requested to revise its reclaimer radon exposure dose calculations, and it is stated that "TFI's evaluation of the Nearest Resident exposure pathways needs to be revised." I am wondering if EPA ever requested these revisions, if TFI ever provided them, and if so, where I might access documentation of those revisions? I have explored all the links included on the EPA's "Approval of Other Uses of Phosphogypsum: Supporting Documents" web page and have been unsuccessful in identifying any such document. Thank you in advance for your time and consideration.

Respectfully,
Audrey Ford

Subject: FOR REVIEW: CMS New Assignment - Candice Marbury - AX-21-000-0547

Good evening Lee,

Attached is a draft response to a control we received last week, as well as the original control letter. Essentially the control asks for EPA to reverse its decision on the use of PG in roads.

This draft response letter has been reviewed by Jon W., Dan, and Jess. The due date for the final response is 11/18.

Please let me know if you have any questions.

Thank you,
Stefanie

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
Washington, DC 20460

November 10, 2020

OFFICE OF
AIR AND
RADIATION

Richard F. Lynen
2209 Summit View Drive
Valrico, FL 33596

Dear Mr. Lynen:

Thank you for writing to the U.S. Environmental Protection Agency (EPA). Administrator Wheeler asked that I respond to your October 20, 2020 letter requesting that the EPA reverse its approval of the use of phosphogypsum in government road construction projects. We appreciate your concerns in this matter.

The EPA's decision to allow phosphogypsum in government road construction projects was based on risk analyses which showed that the use of phosphogypsum in these projects would present no greater risk to members of the public than would be expected if the phosphogypsum were left in the stack. By approving the use of phosphogypsum in government road construction projects, the EPA granted state and local governments the opportunity to investigate whether the use of phosphogypsum in road projects would be appropriate in their jurisdictions. The final decision to incorporate phosphogypsum as a material in road projects rests entirely at the state and local level, and not with the companies that generate phosphogypsum. One condition of the EPA approval is that state or local agencies proposing road projects that use phosphogypsum inform the public of the proposed use and provide an opportunity for public review of the project and associated documents, including the risk assessment upon which the EPA's decision was based.

Once again, thank you for taking the time to follow these important issues and to share your feedback. I appreciate the opportunity to be of service and trust the information provided is helpful. More information on this topic, including EPA's report containing the technical review of the risk assessment, is available at https://www.epa.gov/radiation/approval-other-uses-phosphogypsum-supporting-documents.

Sincerely,

Combined Notice of Filings

Take notice that the Commission has received the following Natural Gas Pipeline Rate and Refund Report filings:

Docket Number: PR20–70–001.

Applicants: Regency Intrastate Gas LP.

Description: Tariff filing per 284.123(b),(e)/: Revised Operating Statement to be effective 6/2/2020.

Filed Date: 10/13/2020.

Accession Number: 202010135157.

Comments/Protests Due: 5 p.m. ET 11/3/2020.

Docket Numbers: RP20–1229–001.

Applicants: Cheniere Corpus Christi Pipeline, LP.

Description: Tariff Amendment: Housekeeping Supplemental Filing to be effective 10/28/2020.

Filed Date: 10/13/20.

Accession Number: 20201013–5193.

Comments Due: 5 p.m. ET 10/26/20.

Docket Numbers: RP21–53–000.

Applicants: Panhandle Eastern Pipe Line Company, LP.

Description: § 4(d) Rate Filing: Housekeeping Filing on 10–13–20 to be effective 11/13/2020.

Filed Date: 10/13/20.

Accession Number: 20201013–5151.

Comments Due: 5 p.m. ET 10/26/20.

Docket Numbers: RP21–54–000.

Applicants: El Paso Natural Gas Company, L.L.C.

Description: § 4(d) Rate Filing: Non-Conforming Agreements Update (NMG) to be effective 1/1/2021.

Filed Date: 10/13/20.

Accession Number: 20201013–5165.

Comments Due: 5 p.m. ET 10/26/20.

The filings are accessible in the Commission's eLibrary system (*https://elibrary.ferc.gov/idmws/search/fercgensearch.asp*) by querying the docket number.

Any person desiring to intervene or protest in any of the above proceedings must file in accordance with Rules 211 and 214 of the Commission's Regulations (18 CFR 385.211 and 385.214) on or before 5:00 p.m. Eastern time on the specified comment date. Protests may be considered, but intervention is necessary to become a party to the proceeding.

eFiling is encouraged. More detailed information relating to filing requirements, interventions, protests, service, and qualifying facilities filings can be found at: *http://www.ferc.gov/docs-filing/efiling/filing-req.pdf.* For other information, call (866) 208–3676 (toll free). For TTY, call (202) 502–8659.

Dated: October 14, 2020.

Nathaniel J. Davis, Sr.,

Deputy Secretary.

[FRL–10015–95–Region 1]

2020 Annual Meeting of the Ozone Transport Commission

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice; meeting.

SUMMARY: The United States Environmental Protection Agency (EPA) is announcing the 2020 Annual Meeting of the Ozone Transport Commission (OTC). The meeting agenda will include topics regarding reducing ground-level ozone precursors.

DATES: The meeting will be held on November 18, 2020 starting at 9 a.m. and ending at noon.

ADDRESSES: Virtual meeting. Further information on the details for the virtual public meeting will be available at *http://www.otcair.org.*

FOR FURTHER INFORMATION CONTACT:

For documents and press inquiries contact: Ozone Transport Commission, 89 South St., Suite 602, Boston, MA 02111; (617) 259–2005; email: *ozone@otcair.org*; website: *http://www.otcair.org.*

For registration: To register for the virtual meeting, please use the online registration form available at *http://www.otcair.org,* or contact the OTC at (617) 259–2005 or by email at *ozone@otcair.org.*

SUPPLEMENTARY INFORMATION: The Clean Air Act Amendments of 1990 contain Section 184 provisions for the Control of Interstate Ozone Air Pollution. Section 184(a) establishes an Ozone Transport Region (OTR) comprised of the States of Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, parts of Virginia and the District of Columbia. The purpose of the OTC is to address ground-level ozone formation, transport, and control within the OTR.

Type of Meeting: Open.

Agenda: Copies of the final agenda will be available from the OTC office (617) 259–2005; by email: *ozone@otcair.org* or via the OTC website at *http://www.otcair.org.*

Dated: October 14, 2020.

Dennis Deziel,

Regional Administrator, EPA Region 1.

Approval of the Request for Other Use of Phosphogypsum by the Fertilizer Institute

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice.

SUMMARY: The Environmental Protection Agency (EPA) is approving, subject to certain conditions, a request by The Fertilizer Institute for use of phosphogypsum in government road projects. This decision and supporting information is being made available to the public through this notice. Under the Clean Air Act, the EPA may approve a request for other use of phosphogypsum if it determines that the proposed use is at least as protective of human health as placement in a stack, which is the designated management method. With this approval, and in accordance with its terms and conditions, government entities may use phosphogypsum for road construction projects.

DATES: October 20, 2020.

FOR FURTHER INFORMATION CONTACT: Jonathan P. Walsh, Radiation Protection Division, Office of Radiation and Indoor Air, Mail Code 6608T, Environmental Protection Agency, 1200 Pennsylvania Ave. NW, Washington, DC 20460; telephone number: (202) 343–9238; fax number: (202) 343–2304; email address: *walsh.jonathan@epa.gov.*

Organization of this document. The information in this notice is organized as follows:

I. General Information
A. How can I get copies of this document and other related information?
II. Background and Overview of Decision
A. The EPA's 1992 Risk Assessment
B. Request by The Fertilizer Institute
C. TFI's Risk Assessment
D. Terms and Conditions of the Approval

SUPPLEMENTARY INFORMATION:

I. General Information

A. How can I get copies of this document and other related information?

1. *Docket.* The EPA has established a docket for this action under Docket ID No. EPA–HQ–OAR–2020–0442. Publicly available docket materials are available either electronically through *www.regulations.gov* or in hard copy at the Air and Radiation Docket in the EPA Docket Center, (EPA/DC) EPA West, Room 3334, 1301 Constitution Ave. NW, Washington, DC. The EPA Docket Center Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Air and Radiation Docket is (202) 566–1742.

2. *Electronic Access.* You may access this **Federal Register** document electronically from the Government Printing Office under the "**Federal Register**" listings at FDSys (*http://www.gpo.gov/fdsys/browse/collection.action?collectionCode=FR*).

II. Background and Overview of Decision

Phosphogypsum stacks are large piles of waste from wet acid phosphorous production. There are more than 60 stacks of phosphogypsum located in 13 different states. The majority of these stacks are located in the southeastern region of the United States. Because the phosphate ore used to produce the phosphoric acid contains relatively high concentrations of uranium and radium, phosphogypsum stacks also contain high concentrations of these elements. The presence of radium in the stacks causes them to release radon gas into the atmosphere.

The EPA regulates the management of phosphogypsum based on its elevated levels of radium and its decay products, including radon gas, which is classified as a hazardous air pollutant under the Clean Air Act. As required by 40 CFR part 61, subpart R (hereafter "Subpart R"), phosphogypsum must be disposed of in engineered piles, called stacks, with the exception of limited use for agricultural and research purposes. In addition, applicants may request approval of other uses of phosphogypsum by following the process prescribed in 40 CFR 61.206.

A. The EPA's 1992 Risk Assessment

The EPA initially established the requirement that phosphogypsum be placed into stacks without any exceptions (54 FR 51674, December 15, 1989). In response to petitions for reconsideration, the EPA re-evaluated the risks of selected applications of phosphogypsum against the risks from stacking (57 FR 23305, June 3, 1992).[1] The EPA determined that the use of phosphogypsum in limited agricultural and indoor research activities could be as protective of human health, in the short- and long-term, as stacking. These approved uses were incorporated into Subpart R at 40 CFR 61.204–205.

The EPA also assessed the use of phosphogypsum in road construction. While the risks were found to be acceptable from most of the exposure scenarios analyzed, the potential risks to residents of dwellings constructed on an abandoned road were calculated to be unacceptably high. The EPA therefore did not approve road construction as a categorical use of phosphogypsum. The EPA did, however, define in 40 CFR 61.206 a process to request approval of other uses of phosphogypsum, including a risk assessment demonstrating that the proposed use is at least as protective of human health, in the short- and long-term, as placement in a stack. As stated in the preamble to the final rule, the measure of protectiveness is lifetime risk of fatal cancer to individuals. In connection with the removal of phosphogypsum from stacks for authorized uses, the EPA incorporated sampling, certification, and record-keeping requirements into Subpart R at 40 CFR 61.207 through 61.209.

B. Request by The Fertilizer Institute

On October 15, 2019, The Fertilizer Institute (TFI) submitted its initial "Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 CFR 61.206," requesting that EPA approve the use of phosphogypsum in road construction. Subsequently, on April 7, 2020, TFI submitted, on behalf of its members that own or operate phosphogypsum stacks, a revised request: "Revised Request for Approval of Additional Uses of Phosphogypsum Pursuant to 40 CFR 61.206: Use in Road Construction Projects Authorized by Federal, State and Local Departments of Transportation or Public Works."

TFI requested that phosphogypsum be approved specifically for government road projects authorized by federal, state and local Departments of Transportation (DOT) or Public Works (PW), and conducted as part of a government road project using appropriate, generally accepted road construction standards and specifications such as ASTM,[2] Federal Highway Administration, federal or state DOT standards and specifications, or standards developed or approved in consultation with the appropriate regulatory DOT or PW authorities. Notably, as envisioned by the request, the submitter of the request (TFI) would not be the entity using the phosphogypsum, although its members may supply the phosphogypsum to the end user (*i.e.,* the government agency responsible for the road construction project). To address this situation, the terms and conditions of the approval require that the phosphogypsum supplier (stack owner or operator) and the end user each provide information to the EPA, as appropriate, prior to removal of phosphogypsum from the stack.

TFI estimates that the cost of transportation would make the use of

[1] "Potential Uses of Phosphogypsum and Associated Risks: Background Information Document," EPA 402–R92–002, May 1992.

[2] Formerly the American Society for Testing and Materials, now ASTM International.

phosphogypsum uneconomical at distances greater than about 200 miles from a stack.[3] In that case, the regional distribution of phosphogypsum stacks suggests that its use for road construction would likely be concentrated in the southeastern part of the country but could also occur in western states such as Idaho and Wyoming.

C. TFI's Risk Assessment

As required by Subpart R, TFI submitted a risk assessment as part of its request.[4] The risk assessment assessed potential exposures to individuals in various scenarios involving road users, nearby residents, and road construction workers. TFI's exposure scenarios and modeling approaches were largely consistent with the EPA's 1992 analysis, as were the overall results.

The EPA finds TFI's risk assessment to adequately demonstrate that the use of phosphogypsum in road construction will be at least as protective of human health, in the short- and long-term, as stacking.[5] However, as in 1992, the EPA remains concerned about potential exposures should the road become abandoned, particularly for a residence built on road material containing phosphogypsum. The EPA does not agree that TFI's assumptions in its analysis of this scenario, such as the use of radon resistant home construction techniques, could be relied upon to limit the potential risks to a future residential individual from such an occurrence. In this case, however, the EPA believes that this risk can be acceptably mitigated by including appropriate terms and conditions in the approval.

In defining its request and exposure scenarios, TFI's risk assessment assumes certain limitations involving the construction and placement of roads. For example, phosphogypsum incorporated into the road base and the road surface is limited in its radium-226 concentration and is assumed to be mixed with other materials in limited proportions. The terms and conditions of the approval reflect these assumptions and limitations.

D. Terms and Conditions of the Approval

The EPA has determined that, subject to the terms and conditions summarized below, phosphogypsum may be removed from stacks and used in government road projects, as requested by TFI. This approval to use phosphogypsum in road construction does not authorize the removal of any phosphogypsum from any stacks or the use of any phosphogypsum for road construction unless and until the information required by the "Initial Conditions," below, is provided to EPA. Only after such information is provided to EPA, may phosphogypsum be removed from stacks and used in road construction, further provided that the conditions expressed in "Other Conditions," below, continue to be met. A complete listing of the terms and conditions applicable to this approval may be found in the approval letter.[6] Additional supporting documentation, such as the complete TFI request and risk assessment, are also in the docket.

1. Initial Conditions

Prior to the distribution and/or use of phosphogypsum for any government road project, the owner or operator of the stack from which phosphogypsum is to be distributed or the governmental entity responsible for building and maintaining the road, as appropriate, must submit to the Agency all information required by 40 CFR 61.206(b), as more specifically described in the approval letter.

2. Other Conditions [7]

Subsequent to the provision of the initial required information to EPA, phosphogypsum may be used in government road projects in accordance with additional conditions, as stated in the approval letter, including, for example, conditions related to:

- Continued control, maintenance, and use of the road;
- Sampling, certification, and record-keeping requirements in 40 CFR 61.206(d) and 61.207 through 61.209;
- Construction of the road consistent with the assumptions, scenarios, limitations, and parameters analyzed in TFI's risk assessment, including an average radium content of no more than 35 pCi/g, no more than 2.25% PG by weight in surface pavement and no more than 50% PG by weight in the road base; and
- Notification and availability of information for the public and road construction workers on the use of phosphogypsum in the road project.

Any use of phosphogypsum not consistent with the terms and conditions and any other limitations set forth in this approval shall be construed as unauthorized distribution of phosphogypsum and may constitute a violation of or noncompliance with 40 CFR part 61, subpart R. This approval is pursuant to Subpart R promulgated under the authority of the Clean Air Act. This approval does not relieve TFI, phosphogypsum stack owners or operators or resellers, retailers, distributors, or end users or other entities handling, processing or using phosphogypsum of responsibility to comply with other applicable laws and regulations.

Andrew Wheeler,

Administrator.

[FR Doc. 2020–23154 Filed 10–19–20; 8:45 am]

BILLING CODE 6560–50–P

[3] "Economic Analysis of Phosphogypsum Reuse," prepared for TFI by Policy Navigation Group, submitted as Appendix 6 to TFI's Revised Request, December 2019, page 19.

[4] "Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum," prepared for TFI by Arcadis Canada Inc., submitted as Appendix 2 to TFI's Revised Request, October 2019.

[5] "Review of the Radiological Risk Assessment Submitted in Support of Request for Approval of Other Use of Phosphogypsum," October 2019, The Fertilizer Institute.

[6] Letter from Andrew Wheeler, Administrator, Environmental Protection Agency, to Corey Rosenbusch, President and CEO, The Fertilizer Institute, Docket No. EPA–HQ–OAR–2020–0442.

[7] In addition to the information required by 40 CFR 61.206(b), as noted in connection with the "Initial Conditions," the "Other Conditions" include conditions associated with the requirements of 40 CFR 61.206(d) and 61.207–61.209; conditions inherent in the nature of or limitations or assumptions associated with TFI's request; and conditions imposed under the EPA's authority and discretion under 40 CFR 61.206(e). The EPA believes that these conditions are either required by 40 CFR part 61, subpart R or are reasonably appropriate to help provide continued assurance that the use is at least as protective as disposal of phosphogypsum in stacks and will ensure that the removal of phosphogypsum from stacks and use in government road projects will be consistent with TFI's request and will occur with public notice and appropriate information availability.

To: Ruth McBurney <rmcburney@crcpd.org>; Mendy Cremeans <mcremeans@crcpd.org>
Subject: EPA Approval of Request for Other Use of Phosphogypsum

Good morning Ruth and Mendy,

During our last board call, I mentioned an upcoming EPA action related to phosphogypsum. Now that it is official, I wanted to let you know that on October 14, EPA approved a request by The Fertilizer Institute (TFI) for use of phosphogypsum in government road construction projects. This approval is granted under the Clean Air Act and the provisions in 40 CFR 61.206, which allow EPA to approve other uses of phosphogypsum if they can be demonstrated to be at least as protective as keeping the material in a stack, which is the designated management method.

This approval is subject to terms and conditions, and we are not aware of any such projects under consideration at this time. A government agency proposing to use phosphogypsum in this manner would have to submit additional information to EPA and provide an opportunity for the public to review the proposal and documents related to this approval, including the risk assessment submitted by TFI. A key condition is that the road not be abandoned or converted for non-road uses, unless additional risk analyses are conducted and EPA is notified.

Attached are the approval letter and the Federal Register notice, which was published today. You can find more information at https://www.epa.gov/radiation/subpart-r-national-emission-standards-radon-emissions-phosphogypsum-stacks. The official docket for this action can be accessed through www.regulations.gov, search for Docket No. EPA-HQ-OAR-2020-0442.

Please let me know if you have any questions. Thanks.
Stefanie

Subject: RE: Request for additional information

Dear Ms. Ford,

Thank you for reaching out with your questions.

The EPA's resolution of the groundwater issues raised by SC&A is included in the EPA summary document, "Review of the Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum Prepared for the Fertilizer Institute," in the section Offsite Individual and Water Pathways, which begins on page 18. I've attached a copy of the document to this email. For its groundwater transport calculations, the SC&A analysis assumed that the phosphogypsum was uncovered by pavement and therefore fully open to infiltration by precipitation, which is not expected to occur. The resultant risks still did not exceed the EPA's threshold for approval. For the crayfish ingestion scenario, in order for risk thresholds to be exceeded, surface water was assumed to already be contaminated by the radionuclides found in phosphogypsum, which is also not expected to occur.

Rather than require TFI to perform additional analyses, the EPA included conditions in its approval which will prevent or minimize contact between phosphogypsum and water. As noted in the EPA summary, "TFI has proposed a generic road design in which phosphogypsum is fully covered by pavement and is therefore protected from infiltration. Additionally, the phosphogypsum is contained in a single, 25 cm layer, which presumably keeps phosphogypsum out of contact with groundwater under typical conditions. As long as these aspects of the generic design are maintained, it is reasonable to expect that the water pathway will not result in unacceptable radiological risks. Should the design change in a way that creates additional exposure of phosphogypsum to water, then this pathway warrants a more involved analysis."

The final approval limits phosphogypsum to a single 25 cm layer, and requires that all phosphogypsum be covered by pavement. With these restrictions in place, the EPA did not require TFI to perform additional analysis of the water pathways. As noted in the EPA's summary, if the design changes or a different design is proposed, these analyses may be required by the EPA at that time.

Hopefully this is helpful. Please reach out if you have any additional questions.

Subject: Request for additional information

To: Jonathan P. Walsh, walsh.jonathan@epa.gov

Good Evening Mr. Walsh,
On October 20, 2020, EPA published a notice in the Federal Register regarding EPA's "Approval of the Request for Other Use of Phosphogypsum by the Fertilizer Institute". One of the technical documents supporting this approval, posted on EPA's webpage dedicated to this issue, is titled "Technical Review of The Fertilizer Institute Risk Assessment for Additional Use of Phosphogypsum in Road Base," dated June 10, 2020. Multiple times in this review document, it is suggested that The Fertilizer Institute (TFI) provide further information and/or analysis on specific issues. For example, on page 46, it is recommended that TFI be required to further explore both the groundwater and ingestion of crayfish exposure pathways; on page 45, it is recommended that TFI be requested to revise its reclaimer radon exposure dose calculations, and it is stated that "TFI's evaluation of the Nearest Resident exposure pathways needs to be revised." I am wondering if EPA ever requested these revisions, if TFI ever provided them, and if so, where I might access documentation of those revisions? I have explored all the links included on the EPA's "Approval of Other Uses of Phosphogypsum: Supporting Documents" web page and have been unsuccessful in identifying any such document. Thank you in advance for your time and consideration.

Respectfully,
Audrey Ford

Subject: TFI Final Comms Plan & Press Release

Good afternoon,

Attached is the final TFI comms plan and press release. The attached items have been revised to incorporate feedback and comments from Charles Starrs. Please note that there are several placeholders in the comms plan. I have confirmed with OAR comms that this is an acceptable practice, and the placeholders can be finalized once the Administrator issues the approval.

Please advise when these materials can also be forwarded (as final documents) to OAR comms.

Thank you,
Stefanie

Subject: The Sun Media Inquiry

Good afternoon Dan,

I have not heard anything from Charles after sending RPD's revised media inquiry responses this morning, or a reminder follow-up email this afternoon. Are you comfortable with me sending the responses approved by Lee (and pasted below) to Kati as final without any further OGC input?

1. Are the underlying assumptions of risk of death due to radiation exposure based on studies of atomic bomb survivors? If not, where do they get the risk of fatal cancer numbers from?

Ex. 5 Deliberative Process (DP)

2. Why did the EPA not allow for public comment on this rule change? When is public comment required?

Ex. 5 Deliberative Process (DP)

3. By government road projects, does this mean just those with federal funding? Not state or local funding?

Ex. 5 Deliberative Process (DP)

4. Will these applications to the EPA come from the phosphate manufacturers or the governmental entity that wants to use the material in road building?

Ex. 5 Deliberative Process (DP)

5. Has the EPA received any applications yet?

Ex. 5 Deliberative Process (DP)

6. How much of an impact can the EPA estimate have on the problem of gypstack formation? Will manufacturers be taking directly off their existing stack or from new material being generated by the manufacturing plants?

Ex. 5 Deliberative Process (DP)

7. how does the EPA estimate the lifetime risk of exposure to the stacks? This is important because the EPA said the relative risk was the same.

Ex. 5 Deliberative Process (DP)

Thank you,
Stefanie

Subject: TFI Media Tracker
Attachments: TFI Media tracker.xlsx

Jess,

Attached is the updated TFI media tracker. 10 new published articles have been added. The tone of the articles has shifted. Previously there was neutral to negative coverage, and as of today, coverage has shifted to primarily negative coverage with a focus on concern for public health. The only exception is one article that covered Administrator Wheeler's visit to Mosaic.

Please let me know if you have any questions or edits. I will send this to Lee before the end of the day.

Thanks!

Subject: TFI Media Tracker

Good afternoon Lee,

Attached is a simple spreadsheet listing various outlets that have covered the TFI action since EPA's press released was announced last Wednesday. The attached only covers traditional media, and not social media. Jessica has seen the attached and asked that I forward it to you.

About half the sources cover the announcement and include an angle (e.g., concern for public health/environment) while approximately half of the sources just share the announcement without any angle. So, I would say coverage is split approximately 50% negative, 50% neutral.

I hope this is helpful. Please let me know if you would like any changes made to the tracker, and when you might want an update on the media coverage.

Thanks,
Stefanie

Hi Joe,

To follow-up on our conversation from this morning, attached are the converted word document files from TFI's recently resubmitted application.

Hope these are helpful!
Stefanie

Subject:
Response to EPA Questions issued on Jan 16, 2020

In response to a set of questions from the United States Environmental Protection Agency (USEPA), related to the risk assessment report submitted in October 2019[1] as support to the petition for beneficial use of phosphogypsum, Arcadis has prepared the following responses and comments.

For each paragraph provided by EPA in their questions, Arcadis has provided a response. Where a full response could not be included in this memo, reference to additional information is provided.

Modeling approach:

1. USEPA: The developers of the risk assessment chose to use a deterministic (vs. stochastic) model using discrete input parameters judged to be typical. From the standpoint of model development, this was a simpler—and potentially clearer—approach. However, a probabilistic approach to model input parameters could have provided the opportunity to incorporate uncertainty and variability into the model, and also could have explicitly included other road designs or variations on road design.

Arcadis: Arcadis intentionally chose a deterministic approach as a full probabilistic approach is quite challenging to present to the public. We recognize that there are variations in scenarios and assumptions and therefore, we intentionally made assumptions and selected parameters that in our view overestimate the potential exposures and doses bracketing the risk. Moreover, the models are linear for key parameters, such as Ra-226 concentration and exposure duration and hence readily scalable. In addition, we believe that the current approach estimates a reasonable maximum exposure (RME).

The RME scenario considers the highest exposure that might reasonably be expected to occur, one that is well above the average case of exposure but within the range of possibility and is intended to provide the basis for estimating the maximum individual risk (MIR). Use of the RME to model baseline human health risks is a conservative approach, in that it yields upper-bound cancer risk and non-cancer hazard estimates (USEPA, 1989). The "intent of the RME is to estimate a conservative exposure case (i.e., well

---

[1] Arcadis 2019. *Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum*, Report to The Fertilizer Institute, October.

above the average case) that is still within the range of possible exposures."[2] Each exposure factor used to estimate the RME should be selected "so that the resulting estimate of exposure is consistent with the higher end of the range of plausible exposures" (citing EPA 1991 guidance).[3]

A National Academy of Science (NAS) Committee reviewing EPA's regulation of technologically enhanced naturally occurring radioactive material (TENORM) recommended that EPA "should use exposure and dose risk assessments that are "reasonably realistic"" in developing standards for exposure to the various types of low level naturally occurring radiation.[4] "The Committee defined "reasonably realistic" as "not … .intended to greatly overestimate or underestimate actual effects for the exposure situation of concern."" and EPA agreed with the Committee's recommendations.[5] The use of reasonable exposure assumptions is supported by the courts, which have long held that exposure assumptions used "must bear some rational relationship" to the actual conditions, and disallowed unduly conservative approaches.[6]

The current deterministic approach of the Risk Assessment focusing on RME scenarios to estimate MIR, provides the best alignment with the purpose of the RA, to compare predicted risks from the proposed use of PG against the risk threshold that is consistent with the determination of a 'safe' level. Overall, the choice of parameters other than those used in the current risk assessment are more likely than not to result in lower doses and risks to the receptor.

Probabilistic (stochastic) approaches would provide added information of the potential variability and uncertainty of the risk at lower risk levels, but overall would not change MIR substantially. In addition, the

complexity of developing subjective probability distribution functions for the model parameters can be quite difficult and often challenging to explain to the general public and thus the probabilistic approach was not selected for the assessment. The modelling approach using deterministic parameters to calculate RME dose and risk estimates was reviewed with EPA in advance of the Risk Assessment.

To illustrate the possible output of a probabilistic approach Figure 1.1 is provided below. The deterministic approach targets calculations for the Maximum Exposed Individual (MEI) or person in the RME scenario, often someone at the upper-end (approximately 90th to 95th percentile) of dose (risk). EPA guidelines state that the assessor may derive a high-end estimate of exposure by using maximum or near maximum values for one or more sensitive exposure factors, leaving others at their mean value.[7] Based on our experience with regulatory decisions, the MIR from a deterministic assessment as performed in our October 2019 risk assessment would be generally comparable to these upper limits of dose (risk).

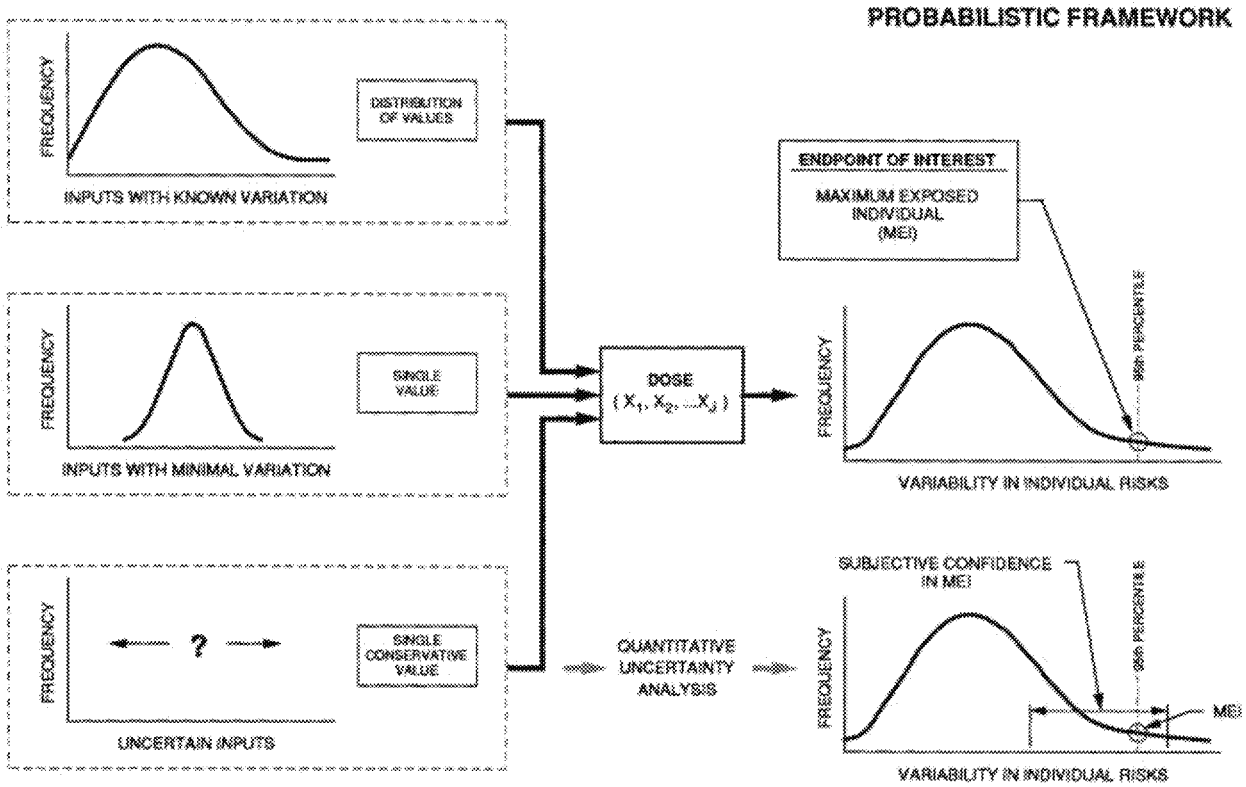
PROBABILISTIC FRAMEWORK



[7] Exposure Factors Handbook: 2011 Edition at (2011) [HYPERLINK "https://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252" \h]

2. USEPA: 61.206(b)(8) requires the risk assessment to include an estimate of the risk distribution.

Arcadis: The original NESHAPS (December 15, 1989 Federal Register) defines a risk distribution estimate as how many persons within a certain distance (e.g. 80 km) of a source of pollutant emissions are at an increased level of individual risk. This requires an estimate of the dispersion of a radioactive pollutant, from a source and an estimate of the population within that distance.

EPA clarified at our meeting that providing more risk distribution information was information on how the risk varied with the "variation of the geometry of exposure" and with different exposure time frames. The RME approach utilized in the risk assessment also serves as a reasonable upper bound on the risk distribution and is a readily accepted approach for not only representing the maximum exposures but also providing insight into risks to people who might be exposed to PG. RMEs are constructed to likely overestimate risks for highest exposure situations; actual risks to these people and risks to the rest of the population would all be lower. Knowledge is relied upon for setting such bounds for the RME and when bounded values are used in calculation, the results are conservative (i.e., higher) estimates of the risks.

Although risk distribution was used in 1989, many EPA risk assessments (including the 1992 BID risk assessment) do not utilize risk distribution. The general risk distribution discussed below is acceptable in this situation.

The radiological "pollutants" associated with PG in roads are direct gamma emissions, particulates, and radon. As shown in the risk assessment, external gamma is by far the dominant source of dose, followed by radioactive particulate emissions and radon.

The gamma exposure dose decreases rapidly with distance, for example at one road used in a Florida Institute of Phosphate Research (FIPR) study, the exposure was indistinguishable from background levels at 50 feet from the road centerline (FIPR, 1989[8]). For the nearby residential exposure scenario, the risk calculated in the October 2019 radiological risk assessment calculated that radiological exposure is always below background levels and reduces with distance from the road, becoming indistinguishable from the variability of background at 50 feet from the road's edge.

Background terrestrial radiation has been shown to have wide variability between states and within states in the US (S. Cohen & Associates 2005)[9].

> *It is instructive to note that not only are there substantially large differences in the average terrestrial doses among states (e.g., 14.3 mrem/yr in Florida versus 42.6 in Colorado), but there are also large differences in the average terrestrial dose rates among cities within a state. For example, in Colorado, the average terrestrial dose rate in Pueblo is 29.2 mrem/yr, while in Denver it is 57.4 mrem/yr. In Las Vegas, Nevada, the terrestrial dose rate is 12.7 mrem/yr, while in non-urban regions of Nevada it is 29.2 mrem/yr.*

[8] Chang, Wen F., Chin, David A., and Ho, Robert, 1989. Phosphogypsum For Secondary Road Construction, University of Miami, For Florida Institute of Phosphate Research, Publication No. 01-033-077, 01-041-077.

[9] S. Cohen & Associates. 2005. Assessment of Variations in Radiation Exposure in the United States Contract Number EP-D-05-002 Work Assignment No. 1-03. Prepared for U.S. Environmental Protection Agency Office of Radiation and Indoor Air 1310 L Street, N.W. Washington, DC 20005.

The USNRP in Report No. 160[10] confirms the range of background terrestrial radiation dose in the USA is variable, depending on local geology and other factors, and ranges from about 10 mrem/y to more than about 40 mrem/y.

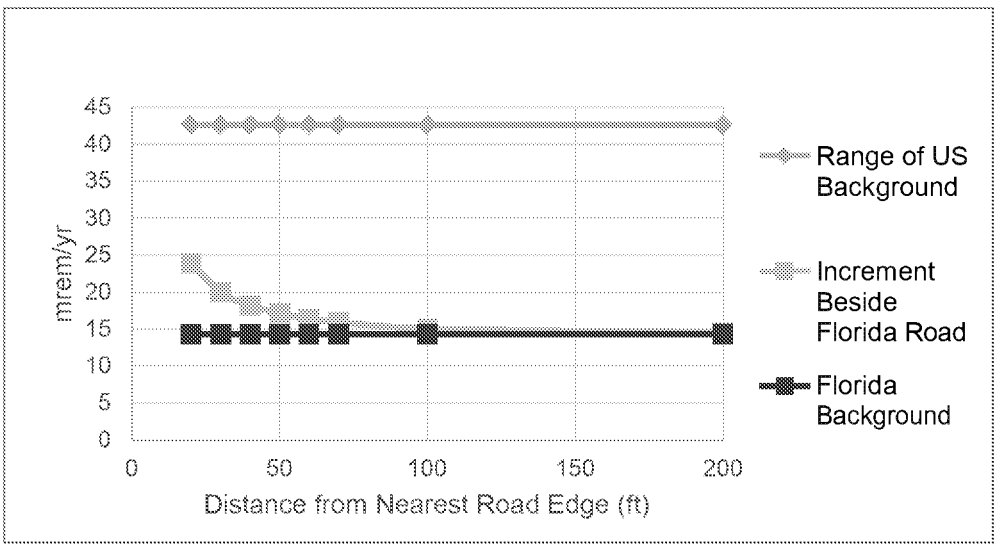
Figure 2 below combines the (notional) background radiation dose in Florida with the incremental dose from a PG road. The figure also displays the upper range of background radiation dose in the US (for Colorado). This clearly shows that dose from a PG road is inconsequential relative to background for distances typical for the closest residence. Further it shows that at distances reasonable for a second closest residence (approximately 100 feet) the dose is essentially zero.

These distances are well short of the 80 km values used in the 1989 risk distribution. Therefore, the contribution to a risk distribution is zero beyond that distance.

Similarly, it was shown in the Risk Assessment that the dose from inhalation and ingestion of particulates was also quite low, less than 10% of the total dose for the worker in the center of the road. As particulate concentration is highest on the road in the construction zone, particulate concentrations reduce with distance from the road and will quickly reach background levels again resulting in zero dose contribution to the risk distribution. In addition, particulate generation is only relevant during construction which occurs for a limited duration in any one location.

Last, is the radon generated from the road. Outdoor radon is quickly disbursed to background levels within a few tens of feet from the road, see for example the measurements on roads constructed with PG. (FIPR, 1989, "Phosphogypsum for Secondary Road Construction"). As previous, the calculated contribution to the risk distribution from radon is zero.

Figure 1 – Incremental External Gamma Dose with Distance Compared to Terrestrial Background



[10] NCRP Report No. 160, Ionizing Radiation Exposure of the Population of the United States

The following table provides summary comments on risk distributions by exposure pathway. The table explains the limited applicability of the RME scenario and the potential for lower exposures and doses to occur for a broader population.

SUMMARY OF RISK DISTRIBUTION FROM USE OF PG IN ROAD CONSTRUCTION		
Exposure Scenarios	RME (small number of people)	Potential Lower Exposures and Risk Distribution
Road Construction Worker	Risk: 0.5 in 10,000 Few if any workers would fit the RME assumption of 100% of workdays on the uncovered road base. The RME worker is exposed to less than 7% of background levels (for all members of the public.	Much less than 0.5 in 10,000 Most workers are expected to spend less than 100% of the workday on the uncovered road base. Dose and risk reduce linearly with reduced exposure time. Time on a covered road base was shown in the Risk Assessment to be a factor of 5 lower. The dose would range down to essentially zero for management and supervision who would spend very limited time on the road and out of vehicles. The number of workers in a road crew is estimated to be as small as 6 – 8 workers, which limits the risk distribution to a small group.
Road User	Risk: 0.1 in 10,000 This RME is assumed to be a heavy user of the road spending 2 hours daily on the road. This scenario is unlikely to occur until far into the future if PG roads become widely available. Until then it is unlikely a commuter would be able to spend this amount of time on a PG road. In the extreme case, the RME road user is exposed to less than 0.3% of background.	Well below 0.1 in 10,000 Most road users will be on the road for much less than two hours per day. Dose and risk reduce linearly with reduced exposure time. Initially when PG use in roads is newly implemented the availability of PG roads will be low reducing the opportunity to have substantive usage time. As the total amount of PG roads increase the risk distribution would increase with additional road users and cumulative usage time. The overall risk to an individual however, is not expected to exceed the RME estimates. Most road users would still have limited time on PG roads and this results in a proportionally limited dose and risk. The overall number of road users is difficult to specify as it depends on several factors including

		the road type and location relative to populated areas. However, the dose to road users would remain a small fraction of that from unavoidable background radiation.
Truck Driver	Risk: 0.5 in 10,000 The Truck Driver RME is limited to workers who participate in PG road construction projects. The assumptions for this scenario are set to estimate the upper end of likely dose and risk for this work. The RME Truck Driver is exposed to less than 6% of background levels.	A truck driver that has less than an RME exposure has lower risk than 0.5 in 10,000. There are a limited number of truck drivers involved in a road construction project. In addition, truck drivers will support numerous construction projects during the course of a year and many not involving use of PG. This limits the risk distribution for this exposure pathway to a relatively small number of people. In many cases, Truck Drivers will not work on PG road construction as much as assumed for the RME, resulting in a lower dose and risk.
Nearby Resident	Risk: 0.08 in 10,000 The Nearby Resident RME is based on extreme assumptions that are unlikely to apply to all residents of a PG road. The assumptions include close exposure to the road and long durations of residency throughout the exposure period. Based on these assumptions the Nearby Resident RME is exposed to 0.2% of background levels.	Most residents near a PG road would be exposed to much lower doses and risk, well below 0.08 in 10,000. Radiation levels from a PG road decrease rapidly with distance from the road and become indistinguishable from background at 50' to 100'. See figure and discussion. As a result, most residents immediately beside a PG road would be exposed to much less than the RME risk level, and residents beyond the immediately adjacent properties would experience essentially zero incremental risk. The overall risk distribution would depend on the overall length of the PG road and population density along the road but is limited to only those locations immediately beside the PG road.
Utility Worker	Risk: 0.004 in 10,000 The Utility Worker RME scenario represents an extreme case where a worker needs to disrupt the road for road or utility maintenance. The assumptions use worst case conditions to estimate the risks	Most Utility Workers would be exposed to risk much less than 0.004 in 10,000. Most utility repair requirements would involve exposure scenarios below those assumed for the RME conditions, due to smaller trenches and exposure areas, or shorter durations.

	and are limited to workers in a trench in a PG road and meeting the other exposure assumptions. The RME Utility Worker is exposed to approximately 0.3% of background levels.	The number of individuals entering a trench in a PG road is also limited based on the uniqueness of the work and the limited space. As a result, the risk distribution for the Utility Worker is limited to a small number of individuals.
Reclaimer Extreme Scenario	Reclaimer is an extreme scenario well beyond an RME assumption and therefore, is not appropriate to determine whether the use of PG is safe. This example for ultimate disposal was selected due to the use by EPA in 1992. Risk: 0.4 in 10,000 The Reclaimer would be exposed to approximately 1% of background levels. (total exposure of 78 mrem compared to a Background of 8,060 mrem over 26 years)	The Reclaimer scenario represents an extreme situation that is unlikely to even occur as described. As a result, the risk distribution is effectively zero. More realistic situations for the ultimate disposal of the road include continued use of the road as a road, or reuse of the PG road base for a new road, if the road was to be relocated or realigned. In the extreme case where a road is abandoned and then the land is reused for other purposes, the land preparation activities will realistically result in blending and mixing of the road base to levels that are indistinguishable from background levels. Overall, the risk distribution would be effectively zero.

In summary, the risk distribution from road construction is negligible, beyond the individuals who are on or immediately beside the road, as assessed in the Risk Assessment document.

3. USEPA: No discussion of uncertainty in model outputs is provided. There is no discussion of uncertainty around model input parameters, with the minor exception of uncertainty of the dose-to-risk conversion factor (p. 1-1). Except for briefly mentioning variability in naturally-occurring background radiation (p. 3-4), the risk assessment does not address variability around model parameters such as exposure factors, activity concentrations, exposure duration, etc.

Arcadis: The Risk Assessment was developed to examine a conceptual road design, to provide an estimate of the upper end RME risks associated with PG use in roads. It is impractical to perform a risk assessment that uses different values for every conceivable road design. Neither the 1989 nor the 1992 BID risk assessment considered every conceivable road design. Many features (such as the number lanes) do not affect the potential exposure. Many other road design features were set at an upper bound RME value and any design that uses different value will reduce the risk or not be an RME.

The following is an example list of factors utilized to minimize the impact of any uncertainties.

- We assumed that EPA's 1992 BID risk assessment used high end assumptions as was the policy at the time. In general, the 2019 radiological risk assessment is more conservative (i.e., results

in higher exposures) than the 1992 BID. The 2019 radiological risk assessment used the same exposure scenarios plus two new exposure scenarios.

- In conjunction with the submission of the Petition, TFI members agreed to perform radiological testing of PG. Nine PG stacks located in Central Florida (where the highest Ra-226 levels would be expected), Louisiana, and the Western U.S. with ten samples taken from each stack, for a total of 90 samples.4 A summary of the results is as follows:
    - The average Ra-226 concentration of all 90 samples is 18.6 pCi/g.
    - Ra-226 concentrations in individual samples range from 6.3 pCi/g to 27.9 pCi/g.
    - The average Ra-226 concentration from the 2019 stack sampling (18.6 pCi/g) is below the radioactivity concentration limit of 35 pCi/g proposed in the Petition, and well below the average Ra-226 concentration of 148 pCi/g that corresponds to an EPA safe risk level of 3 in 10,000.
    - No individual concentration from the 2019 stack sampling (with concentrations ranging from 6.32 pCi/g to 27.9 pCi/g) exceeds 35 pCi/g.
- The EPA 1992 BID assumed a 1:2 dilution of PG with soils for a road base concentration of 10 pCi/g. The October 2019 risk assessment utilized less dilution (1:1 PG:soil).
- The EPA 1992 BID assumed the road base was 0.25 m thick and 30 feet (9.15m) wide and that the road base is covered with a 0.12 m (5 in) thickness of asphalt. The October 2019 risk assessment utilized a road thickness of 0.25 m (the same as in 1992).
- The EPA 1992 BID assumed PG in a concrete road incorporates 15% PG by weight and 0.12 m thick (5 in) and 24 feet wide (7.32 m). The October 2019 reviewed road base design criteria and concluded 15% was a high-end criterion.
- The EPA 1992 BID used exposure to the critical population group member (nearby resident 100 m (i.e., 328 ft) from the edge of the road). The October 2019 radiological risk assessment calculates the radiation levels at 50 feet from the edge of the road.
- The current risk assessment assumes a worker moves around over the road surface and is exposed at the average of the gamma fields at the center and edge of the road, which is more reasonable than assuming a worker never moves for 5 years. The stationary worker is not realistic or reasonable, therefore it is not an RME.
- The 1992 EPA risk assessment used a 0.6 shielding for the road user, but rather than determine the degree to which vehicles have changed the amount of metal in the under carriage of cars, the current risk assessment takes no credit for shielding provided by the vehicle which however would provide some level of shielding which is a conservative assumption and could reasonably be considered.
- The current risk assessment considered two receptors beyond those considered in the 1992 BID (truck driver and utility worker).

Given the fact that each of the exposure assumptions are RME (including road design parameters), the uncertainty is addressed with the risk assessment without having to perform numerous risk calculations that will simply confirm the nature of the RMEs utilized. If EPA identifies any road design factors that increase the radiological risk and are RME, the Petitioners will evaluate it. In summary, as described in the first item under Modelling Approach above, the selection of deterministic parameters was done at the conservative end of the expected range of uncertainty, to provide calculations tending to overestimate expected results.

Conceptual road model:

4. USEPA: What is the generic composition (in more detail) of a road? For example, if road base is to be composed of a mixture of soil and PG, what are the ranges of composition of the soils to be used (e.g., organic carbon content, clay contents, moisture).

Arcadis: The Risk Assessment is intended to provide a conceptual exposure model of PG use in roads and is not linked to a specific road segment approval.

The selected example road was a four-lane county road with two lanes in each direction. This type of road is common in rural, suburban and urban settings and represents the type likely to be constructed by state and local governments who can employ PG during construction.

Choice of this road type permits evaluation of construction workers, nearby residents, bicyclists and motorists, and utility workers. The road dimensions are 15 m wide (about 12 feet [ft] per lane) and 100 m long (segment length) for modelling exposures. The thickness of the road base containing PG and road surface (i.e., pavement) are 0.25 m and 0.12 m respectively consistent with the EPA BID (1992).

The road base in the example road was selected to be PG mixed with in-situ soil, as it is the most probable choice to mix with PG. This soil would likely be used whether or not PG was used in the road base mix and is not considered as a risk variable. The soil-PG mixture will be compacted as part of the road construction process leading to high densities in the road base. Other site-specific soil parameters were not defined and are generally less important to the overall risk calculations. Specifically, carbon or clay content and moisture levels are not key factors in the risk determination (i.e., the radiation levels do not vary significantly based on these factors. Gamma ray attenuation for a fixed thickness of shielding is based on the density of the material being penetrated and to a lesser degree the chemical composition. The gamma source strength for a large slab of gamma emitting materials is proportional to the source strength (disintegrations per cc per sec) and inversely proportional to the mass attenuation coefficient[11]. The first term, source strength, can be rewritten as Bq/g x g/cc (pCi/g x g/cc). The second term, mass absorption coefficient is the linear attenuation coefficient divided by density. Both terms are dependent on density (i.e., g/cc or equivalent units). Thus, for practical purposes, the density of the source material is the key factor irrespective of the characteristics of the source material per se.

5. USEPA: What is the basis for limiting phosphogypsum to 50% in the road base? Is there a geotechnical reason, such that structural stability suffers at higher proportions? Is there an optimal range for durability? Alternatively, would administrative controls need to be put in place to maintain this limit during construction? Would an end-user need to address the administrative controls in a specific use request?

Arcadis: Available research on experimental roads reported PG:soil ratios in the range of 1:2 PG:Soil. The EPA in their 1992 BID used a 1:2 mix of PG:sand. This is also the PG ratio in the Polk and Columbia county roads[12] constructed with input on the design and testing of the roads from the University of Miami and the Bureau of Materials & Research, the Florida Department of Transportation.

[12] Chang, Wen F., and Mantell, Murray I., 1990. Engineering Properties and Construction Applications of Phosphogypsum, University of Miami, Phosphate Research Institute, ISBN No. 87024-328-4.

In a study by W.F. Chang et at (Chang, Wen F., Chin, David A., and Ho, Robert, 1989)[13], various ratios of PG to soil were studied. California Bearing Ratio CBR test were conducted on ratios of PG: sand ranging from 100% sand to 100% PG. The PG to sand mixtures showed all mixes had CBR values higher than sand or PG separately. Various radios of PG to soil were used in sections of an experimental road in Polk County Florida. The PG was rototilled into the soil to various depths, A portion was also covered by an asphalt coat. These studies indicate that there is no reason to limit the quantity of PG to be used in a road. The limiting factor would be the measured compressive strength and durability of the admixtures prior to their use in the road. Further studies could establish guidance on the range of PG to soil ratio allowed for various soil types. A 50:50 mixture of PG and local construction materials such as sand or soil is likely to be an overestimate of the actual mix

As noted in the figure below, road design parameters and specifications are better optimized at lower PG:soil ratios. To be conservative of potential risks, the risk assessment considered the upper end of likely reasonable mixture ratios. As stated in previous comments, this parameter provides a linear impact on the risk results. So, if alternate concentrations of PG are desirable, the risks can be easily extrapolated up or down from the existing calculations.

The amount of PG that would be used in a lane/mile of road base depends on many things such as: thickness of the road base, the percent PG in the road base, density of the PG, width of a "lane". In the end, the appropriate County, State or Federal road authority will have to approve the specifications of the road base used in the design. However, to illustrate the concept, consider a road where 1) lane width is 25 feet, 2) the maximum thickness of the road base mix is 12-inches, 3) the maximum percent PG in the road base is 50%, 4) the dry density/95% proctor can be based off the attached Figure 3.6 from Chang and Mantell 1990[14].

The Figure 3.6 Maximum density curve is based on a PG soil mix, it provides the highest density with PG at 1/6 of the mixture – which can then be extrapolated using the curve for a half/half mixture. Using this range yields a 95% proctor density of 1.9 to 1.98 grams/ cubic centimeter which converts to 118.6 to 123.6 lb/cubic ft.

That said, a 25 ft wide lane for one mile, would require about 3,900 to 4,100 tons of PG per mile, rounded to 4,000 tons/mile.

However, it is the concentration of Ra-226 in the road base that determines the gamma radiation levels. For example, a road with PG at 1/6 of the mixture as described above would have a Ra-226 concentration 3 times lower than the calculations provided in the 2019 risk assessment, and result in doses and risks 3 times lower. As previously indicated, the 2019 risk assessment assumed a 1:1 mix of PG and local soils. This is considered a reasonable upper bound for such a mixture and hence alternative mixtures will have lower concentrations of Ra-226 than were assessed in the 2019 risk assessment and hence, it follows that the doses and risks would also be lower.

36 PHOSPHOGYPSUM

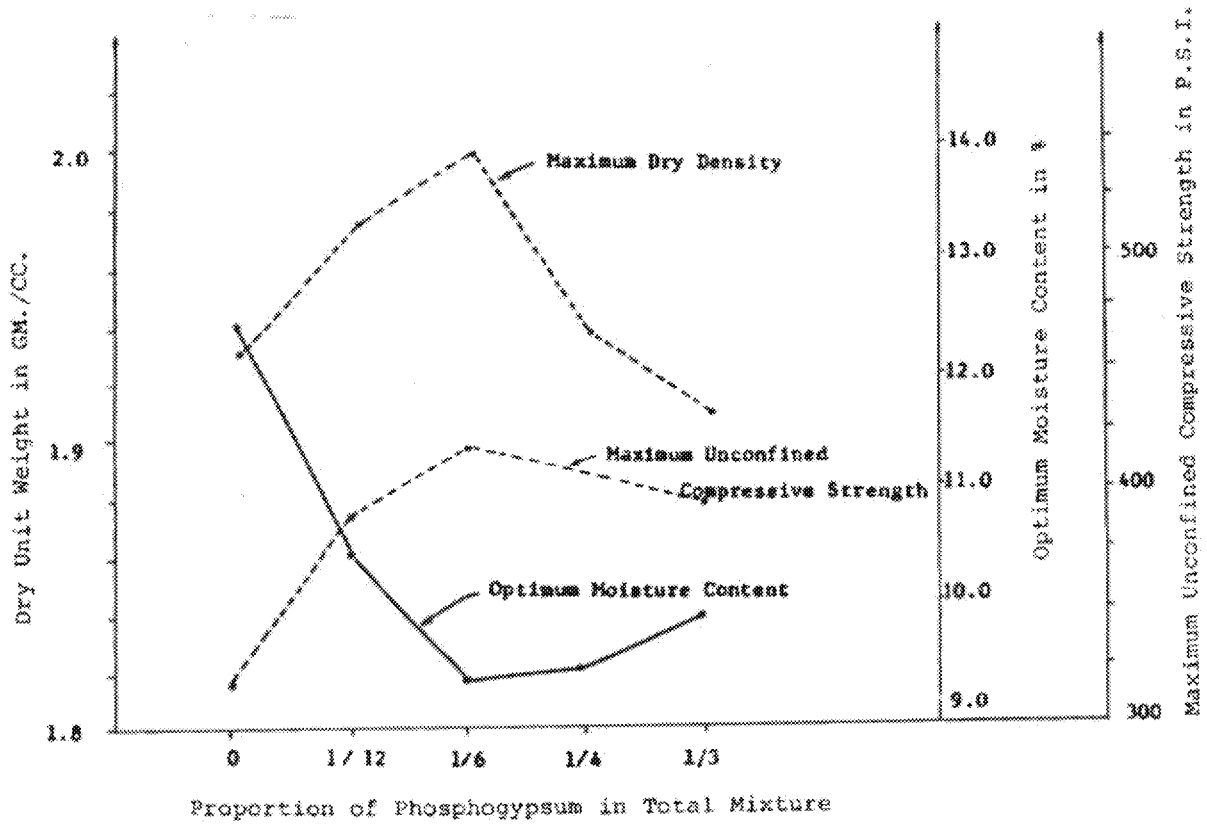

Figure 3.6 Variation in the maximum unconfined compressive strength, optimum moisture and maximum dry unit weight with change in the proportion of phosphogypsum in the various mixtures of clayey sand, sand and phosphogypsum.

6. USEPA: Reviewers had questions related to the conceptual model for the road design, specifically the restriction of the phosphogypsum-containing layer of road base to the area under the pavement. A road model used by the U.S. Federal Highway Administration, "Tech Brief: Bases and Subbases for Concrete Pavements," FHWA-HIF-16-005 (https[HYPERLINK "http://www.fhwa.dot.gov/pavement/concrete/pubs/hif16005.pdf)" \h].fh[HYPERLINK "http://www.fhwa.dot.gov/pavement/concrete/pubs/hif16005.pdf)" \h]shows a road base which extends 3 to 4 feet (91 to 122 cm) beyond the road cover on each side of the road. In this case, all scenarios would need to account for some gamma exposure from road base material that is not shielded by pavement, and the possibility that phosphogypsum may become airborne at the uncovered edges of the road base.

Arcadis: The risk assessment provided an examination of a conceptual road design with risks estimated for scenarios and exposure pathways expected to be the most dominant. The road design in the risk assessment approximated road design characteristics and plausible exposure scenarios for various types of roads. While some large highways may have exposed shoulders, those roads are unlikely to have pedestrians, cyclists or houses in close proximity. Suburban and urban roads represented a plausible

scenario which maximizes exposures for the dominant external gamma pathway. Airborne dust from exposed shoulders is not expected to be a dominant pathway due to the binding properties of PG and the limited potential for substantive intake. Further, road shoulders typically become infilled with vegetation which also suppresses dust.

To explore this question, Arcadis considered the dose and risk impacts for a conceptual road with a 4-foot uncovered shoulder. We estimated results that are not substantially different from that of the original conceptual design of a 15-meter-wide road. Consider the worst case a worker at the center of the road. Gamma rays emitted from the strip (consider the leading or close edge or 7.5 m from the center) would need to travel at an extreme angle (~7.6 degrees) to impact a worker at the center of the road at the dose point (one meter above the surface. From the far edge (8.7 m form the center) the angle is 6.6 degrees. Assuming gamma rays are emitted isotropically, then about 1% of the additional emitted gamma rays (1/90) strike the worker.

Additional gamma calculations were also done with RESRAD for an uncovered road shoulder as described below to confirm the above estimations. Two cases were run with all the parameters fixed with the exception of the area. The original area was 15 m by 100 m, the adjusted area was 17.5 m by 100 m. Table 1 presents the exposure for a worker at the road center in both cases. As indicated the maximum contribution to the dose is external gamma. The increase in dose for external gamma is about 1.5%

Table 1 Dose to a maximumly-exposed worker at the center of a road with constructed with PG

	Direct exposure mrem/year	Inhalation dose mrem/year	Inhalation Dose mrem/year	Total Dose mrem/year
Original Road (15 m x 100 m)	26.11	0.1423	1.918	28.170
Adjusted Road (17.5 m x 100 m)	26.51	0.1465	2.004	28.661
Increase %	1.5%	2.9%	4.4%	1.7%

A similar calculation can be performed with the exposure point at the edge with similar results. The conclusion is that the 3- to 4-foot (i.e., 1 m to 1.2 m) strip along the road has minimal increase in the dose and final risk.

7. USEPA: Are assumptions related to durability and weathering of roads based on documented experience? What are the assumptions regarding the frequency of repaving or other road maintenance/replacement? Are they correlated to the type of road and traffic projections? Would an end-user need to account for such assumptions in a specific use request?

Arcadis: Road maintenance related to weathering roads was not explicitly assessed in the 2019 risk assessment, nor was road maintenance assessed in the EPA 1992 BID. This scenario is not deemed to be an RME condition and would be bounded by risks calculated for the Road Construction Worker. Consequently, road type and traffic projections are not relevant to the risk assessment and would not need to be accounted for in a specific use request.

Potential doses arising from road maintenance are expected to be on the order of those from the Utility Worker scenario. Full repaving activities would be limited to exposures less than those arising from road construction.

Road maintenance is typically done by milling the surface, cleaning, applying tackifier (to assist in binding new asphalt to the underlying asphalt) and new asphalt, leading to minimal disruption of the road base (the PG containing layer). Section 10.5.3 of IAEA 78 Safety Report Series[15] provides several observations on use of PG for road base and suggests PG roads would require less frequent maintenance as compared to roads constructed with other clay-based and limestone materials.

> *Phosphogypsum has successfully been used as a binder for base course mixtures. Phosphogypsum based mixtures are more workable than clay based mixtures. Delays due to rain during construction are reduced because the compacted mixture does not absorb significant amounts of water. Shrinkage cracks and swelling, which often negatively affect the performance of clay based road beds, are greatly reduced. The stability of compacted phosphogypsum mixtures is superior to that of clay mixtures [186] and there is evidence that the use of phosphogypsum, if correctly optimized, leads to a progressive strengthening of the road bed over time [214, 215].*

Further as regards maintenance to date experience indicates minimal maintenance.

> *In Florida, USA, two experimental roads were built in 1986–1987 using both dihydrate and hemihydrate forms of phosphogypsum [224, 225]. The results of the evaluations are reported in Refs [226–228]. It was concluded that phosphogypsum, when subjected to optimum mixing and compaction, could be transformed into a solid of high strength that is effective as a binder to stabilize on-site soil. Phosphogypsum and sand mixtures, stabilized with a small amount of cement, possessed a load bearing capacity higher than that of locally mined limestone, which was at that time the material of choice for road bases in the region. It was also demonstrated that the incorporation of phosphogypsum into a cement based mixture for making 'roller compacted concrete' (a form of concrete widely used for road construction) led to improved compaction and strength properties [229]. The road bed described in Ref. [224] is shown in Fig. 49, which shows the condition after 25 years of use. The picture was taken during routine resurfacing. While the phosphogypsum is clearly not mixed in fully with other road bed materials, it has, nevertheless, lost none of its load bearing strength. As a result, the only maintenance requirement was a new layer of asphalt.*

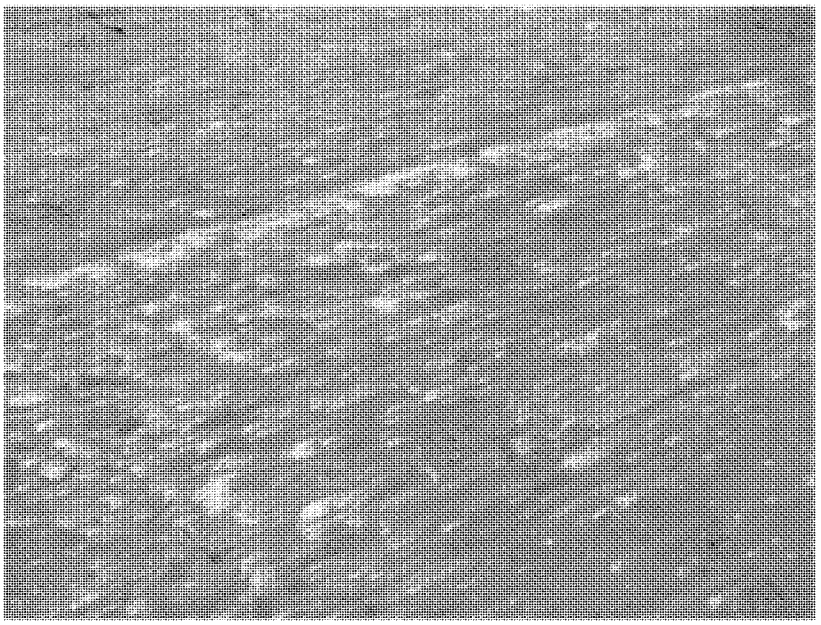

FIG. 49. Experimental road bed in Florida, USA, incorporating phosphogypsum (courtesy: Florida Industrial and Phosphate Research Institute).

In summary, the dose and risk from repairs conceptually cannot be greater than the dose and risk from the original road building since the PG is covered by concrete, asphalt or other material. The Risk Assessment provides the RME scenarios representing categories of exposure conditions with other minor exposure scenario representing lower risks. The example of road maintenance is not considered an RME and requires no further assessment.

Environmental and exposure pathways:

8. USEPA: The risk assessment would benefit from additional analysis of water pathways. Appendix 3 states that "Leaching to groundwater (or surface water) is likely not a complete exposure pathway for the petitioned PG reuse in road construction. This is because roadways are sloped to drain precipitation and paving will act as a barrier to infiltration through the compacted road base beneath. Despite this, literature regarding leaching and water quality was evaluated as part of this screening assessment (see the section titled "Leaching and Water Quality")." (p. 4) At least qualitative consideration should be given to direct contact with surface or groundwater due to flooding events, high water tables, and the presence of karst in phosphate lands. Likewise, reviewers suggested that the risk assessment consider the weathering of the road – will it develop fractures, potentially leading to infiltration resulting from road weathering cause leaching?

Arcadis: Previous risk assessments including 1992 Background Information Document for "Potential Uses of Phosphogypsum and Associated Risks", EPA 1992[16] and SENES 1997[17] examined the potential for impacts to groundwater and surface water pathways. These studies found no realistic potential for impacts to these pathways. Groundwater and surface water pathways were identified to be inconsequential by the EPA BID calculations. Radionuclides were not calculated to reach the nearby well water via the groundwater for almost 10,000 years. For off-site (more distant) wells and river water, radionuclides were not calculated to reach these waterbodies via groundwater for almost 100,000 years. The EPA BID reported in Note C, Table 4.15, that groundwater velocities and retardation factors in the modelling were the factors contributing to this result.

> *No radionuclides are calculated to reach the on-site well via the groundwater pathway for almost 10,000 years, or the off-site river or well for more than 100,000 years because of groundwater velocities and retardation factors.*

Exploratory calculations were completed by SENES Consultants Limited (1997) (now Arcadis Canada Inc.) to review how EPA calculations for the Background Information Document (BID) and Final Rule. SENES reconstructed the BID calculations with nearly identical results as shown in Table A.1 from SENES 1997. With respect to water pathways, the results were consistent, showing that there was no impacts or very limited results, orders of magnitude below other pathways of interest, as shown in the table.

Table A.1

BID RECONSTRUCTION RESULTS
(Asphalt Road Constructed Using Phosphogypsum Containing Radium-226 At 26 pCi/g)

	Comparison of BID results and reconstructed results Dose, mrem per year (Lifetime risk per year of exposure)	
	BID Dose(Risk)	BID Reconstruction Dose(Risk)
Construction Worker - gamma no shielding from equipment - gamma with shielding from equipment - inhalation of dust - dry site - inhalation of dust - humid site	 41 (1.5×10^{-5}) 25 (9.0×10^{-6}) 2.5 (2.2×10^{-7}) 1.0 (8.4×10^{-8})	 42 (1.3×10^{-5}) 25 (7.6×10^{-6}) 2.5 (2.1×10^{-7}) 1.0 (8.6×10^{-8})
Person driving on road - gamma	 0.22 (8.2×10^{-8})	 0.23 (7.2×10^{-8})
Critical Population Group - gamma, 100 m off-site - ingestion of well water - ingestion of food	 0.043 (1.6×10^{-8}) —[a] —[a]	 $<1.0 \times 10^{-7}$ ($<1.0 \times 10^{-13}$)[a] 0.0037 (8.2×10^{-10})[b] —[b]
Off-site Individual - river water from groundwater - river water from surface runoff	 —[c] 0.02 (1.5×10^{-9})	 —[c] 0.02 (2.2×10^{-9})

Notes:

a. Critical Population Group gamma dose estimates are less than the stated values. These values were calculated in MicroShield without taking account of shielding provided by the upper layer of road material. Risks for this pathway are calculated based on a risk factor of approximately 3.9×10^{-7} $mrem^{-1}$ (EPA 1989). As MicroShield does not provide radionuclide-specific doses, this alternative approach to the risk calculation was utilized. For further information see Part II, Section 3.3.

b. The values stated for well water ingestion by the CPG correspond to year 10,000. No radionuclides were calculated to reach the well water in any of the prior years that were calculated. The food pathway for the CPG was not modelled as it is expected to have a similar result, or less, than the well water pathway. This is based on the BID assumption that food eaten by the CPG is irrigated with well water.

c. For these pathways, no radionuclides were calculated to reach the on-site well via the groundwater pathway for almost 10,000 years, or the off-site river or well for more than 100,000 years because of groundwater velocities and retardation factors.

9. USEPA: Related to the question of whether interactions with ground and surface water are possible, if dissolution or leaching does take place, is there a potential for uptake and bioaccumulation by organisms of any of the radiological constituents of phosphogypsum?

Arcadis: As noted above, radiological groundwater and surface water impacts were not expected to be relevant in the overall risk determinations for this potential use of PG. By extension subsequent

pathways to groundwater and surface water were shown not to be relevant, as documented in BID 1992, Table 4-15 and SENES 1997, summarized in Table A.1 above.

Exposure scenarios/receptors:

10. USEPA: The risk assessment should address the handling of the phosphogypsum between the stack and road construction. The risk assessment should incorporate all handling and processing steps necessary to implement the use. Presumably, pure phosphogypsum would be trucked to a batch plant or other mixing facility, prior to transportation to the construction area. These scenarios should be explicitly considered, including the potential for dust and surface runoff.

Arcadis: Known construction procedures involve PG mixing at the road construction site by placing the PG in the desired location and mixing it into existing or additional soil. Existing calculations consider dust generation at the construction site. These dust intake pathways were found to be orders of magnitude less than external gamma exposure for the construction worker. PG is not batched or mixed prior to use. With respect to loading PG in a truck, the frontend loaders and/or scrapers used to remove PG from a stack to a holding area stockpile at the plant facility for subsequent loading are closed air-conditioned cabs.

Any potential dust exposure to the truck driver or equipment operator is expected to be substantially less in concentration and duration of exposure, compared to the construction worker

For example, as can be seen in the RESRAD output in Appendix C of the Draft Risk Assessment, the annual dose for a road construction worker at the center of the road working on exposed road base, who would experience more direct exposure than a truck driver, inhalation exposure represents 0.5% of the total annual dose. This is presented in the table below.

Road Construction Worker Uranium-238 Dose Exposed to Road Base at Center of Road			
Total Annual Dose (mrem/year)	External Gamma (mrem/year)	Inhalation (mrem/year)	Incidental Ingestion (mrem/year)
28.17	26.11	0.1423	1.918
100.0%	92.7%	0.5%	6.8%

Consequently, the contribution of dust intake for the truck driver or equipment operator is not expected to be relevant to the overall dose and risk calculation.

In addition, consider potential gamma exposures as illustrated by an equipment operator loading the truck using a medium frontend loader. The rate of loading for a 2.25 cubic yards (cy) capacity bucket is 100 cy/hour (Means 2000). Assuming the operator fills ten 20 cy trucks results in an exposure time of two hours per day. In addition, the operator of the front-end loader would be inside a cab located above the PG stack and shielded by the cab. The cab shielding (1 cm of steel) reduces the gamma dose by 50%. This results in the cab operator receiving an annual dose of about 10 % of the construction worker dose (25% exposure duration-2 hours/day and less than 50 % of the gamma dose). The risk is also reduced by at minimum a factor of ten.

11. USEPA: The truck driver scenario only includes direct external exposure from gamma radiation. It should explicitly consider inhalation or ingestion during loading, unloading and truck cleaning.

Arcadis: See comments above. While these additional exposures can be developed, given the discussion in the previous comment, we see no realistic potential for a substantive increase in the calculated risk due to inhalation and ingestion of dust. As described in the response to comment 10, the annual dose for a road construction worker at the center of the road working on exposed road base, who would experience more direct exposure than a truck driver, inhalation exposure represents 0.5% of the total annual dose and ingestion represents 6.8% of the total dose. As a truck driver in the cab of a truck would have less exposure via these routes of exposure than a road construction worker, the relatively small incremental increase in dose has little impact on the resulting risk estimate. Assuming similar percentages for inhalation (0.5%) and incidental ingestion (6.8%) for the truck driver scenario with an annual dose of 18.6 mrem/year, inhalation would be 0.09 mrem/year and ingestion would be 1.27 mrem/year for a total of 20 mrem/year. However, ultimately once converted to risk over a 5-year exposure duration the resulting cancer risk (presented to one significant figure) remains the same (i.e., 20 mrem/year divided by 1,000 mrem/rem, multiplied by the cancer risk coefficient of 5.0×10^{-4} per rem = 5×10^{-5}).

12. USEPA: The utility worker scenario should consider a worker in a trench that parallels the road, rather than crossing it.

Arcadis: For the Utility Worker Arcadis selected a trench that crosses the road to simply represent an RME scenario, providing a near upper-limit exposure. This scenario provides exposure to an excavated surface on both sides of the worker. The exposure rate as reported in the Risk Assessment is 4.2 µR/hr.

Considering a trench that parallels the road on either side provides only one exposed surface. The result is an exposure rate approximately half (2.15 µR/hr) of the exposure rate arising from the trench considered in the 2019 Risk Assessment. Below are excerpts of a MicroShield output for a trench along the length of the road.

MicroShield Output for Trench Along Length of Road

Source Dimensions	
Length	1.5e+3 cm (49 ft 2.6 in)
Width	1.0e+4 cm (328 ft 1.0 in)
Height	25.0 cm (9.8 in)

Dose Points			
A	X	Y	Z
#1	1.6e+3 cm (51 ft 10.8 in)	25.0 cm (9.8 in)	5.0e+3 cm (164 ft 0.5 in)
#2	1.6e+3 cm (52 ft 10.8 in)	25.0 cm (9.8 in)	5.0e+3 cm (164 ft 0.5 in)

		No Buildup	With Buildup	No Buildup	With Buildup
Totals	**1.111e+09**	**5.692e-01**	**1.237e+00**	**9.726e-04**	**2.149e-03**

In the extremely unlikely scenario of a 100 m trench down the center of the road, the resulting exposure rate is estimated by assuming two exposed surfaces results in an exposure rate of 4.3 μR/hr. The incremental length of the trench provides no substantive increase in dose rate due to the extreme angle and distance of the additional exposed surface.

13. USEPA: There may be road user scenarios worth considering, particularly if phosphogypsum may extend beyond the paved areas, e.g., pickup/delivery drivers, workers who mow the shoulders. How would these compare to the currently-modeled scenarios?

Arcadis: As discussed in a previous question, the risk assessment provided an examination of a conceptual road design with risks estimated for scenarios and exposure pathways expected to be the most dominant. The examined exposure scenarios were included in the risk assessment in order to provide the likely maximum scenarios and the scenarios were agreed to by EPA.

The conceptual road design in the risk assessment approximated road design characteristics common in rural, suburban and urban settings and provided plausible exposure scenarios for various types of roads. While larger highway designs could be built, these require larger right-of-way widths of approximately 150 to 300 feet.[18] This leads to larger set-backs for near-by residential housing, resulting in lower dose and risk. Interstate highways typically have restricted access to cyclists and pedestrians, eliminating these

[18] The Federal Highway Administation, Highway History, The Size of the Job, available at [HYPERLINK "https://nam02.safelinks.protection.outlook.com/?url=https%3A%2F%2Fwww.fhwa.dot.gov%2Finfrastructure%2F50size.cfm&data=02%7C01%7Cjohn.stolys%40arcadis.com%7Cbc120b78c8454cab9dbe08d7d46f8afe%7C7f90057d3ea046feb07ce0568627081b%7C1%7C0%7C637211449697708910&sdata=ZhCvQ

exposure scenarios for large highways. Suburban and urban roads represented a plausible scenario which maximizes exposures for the dominant external gamma pathway.

With respect to pickup/delivery drivers and workers who mow the shoulders the dose assessments for road users provided in the 2019 risk assessment would be bounding and estimate higher doses than doses for other types of road users.

For example, a truck driver may drive 50% of the workday but would likely be on PG road only 25% of the driving hours due to the use of the extensive network of existing roads. Drivers in delivery trucks would also gain the benefit of shielding from the vehicle structure, which is typically a factor of approximately 0.6 (BID 1992). Overall, a scenario with a delivery driver is estimated to result in a dose that is approximately 30% of that estimated for the road user in the 2019 risk assessment.

A worker mowing the grass beside the road may be working for close to a full day but again would likely be beside a PG road only 25% of the driving hours due to the work on the extensive network of existing roads. This worker would also gain the benefit of shielding from the vehicle structure, which is typically a factor of approximately 0.6 (BID 1992). Considering the worker is located beside the road, the exposure to PG is reduced by approximately 50%, as shown in the 1992 risk assessment. Overall, a scenario with a worker mowing grass beside the road is estimated to result in a dose that is approximately 30% of that estimated for the road user in the 2019 risk assessment.

Parameters:

14. USEPA: The worker exposure duration of 5 years is based on both 25% of a 20-year career and of 70% of the project completion time for a major road project (p. 2-9). If the use of phosphogypsum as road base becomes regular practice, would workers not be expected to work on subsequent projects that could also involve phosphogypsum?

Arcadis: The road construction project examples provided in the discussion of this parameter were some of the largest (longest) projects identified. The parameter estimation uses worker statistics and the likelihood of other road construction methods to continue, to estimate a reasonable exposure duration over a construction worker's career.

The Bureau of Labor Statistics employee tenure in 2018 shows that the median years of tenure with current employer for construction industry between 2008-2018 ranges from 3.5 years in January 2008 to 4.3 years in January 2012 (See Table 5 below).

Table 5. Median years of tenure with current employer for employed wage and salary workers by industry, selected years, 2008-2018

Industry	January 2008	January 2010	January 2012	January 2014	January 2016	January 2018
Total, 16 years and over	4.1	4.4	4.6	4.6	4.2	4.2
Private sector	3.8	4.0	4.2	4.1	3.7	3.8
Agriculture and related industries	4.3	4.8	4.1	3.8	4.5	4.6
Nonagricultural industries	3.8	4.0	4.2	4.1	3.7	3.8
Mining, quarrying, and oil and gas extraction	4.1	4.8	3.5	4.0	4.8	5.1
Construction	3.5	4.2	4.3	3.9	4.0	4.1

Burmaster (2000)[19] analyzed employee tenure data from The Bureau of Labor data. The report provides statistical analysis of those data for a wide variety of occupations. For construction in general, the data for men (women not available) show a mean and 95th percentile of 3.23 yr and 12.48 yr. For construction laborer's specifically, the data for men/women show a mean and 95th percentile of 1.74 yr / 1.81 yr and 5.93 yr / 7.08 yr, respectively.

Burmaster (2000) also provides the distributions (in terms of empirical percentiles) for projected duration in years for each occupation type. The table below shows the worker tenure percentile projections for these selected industrial subsectors.

Distribution of Male Worker Tenure by Industry Type

Industry Sector		Percentiles											
	Mean	10	20	30	40	50	60	70	80	90	95	97.5	99
Construction	3.23	0.21	0.45	0.74	1.10	1.54	2.13	2.98	4.39	7.70	12.48	18.24	26.23
Construction Labor	1.74	0.10	0.22	0.36	0.53	0.74	1.01	1.40	2.03	3.45	5.93	11.53	21.26

To be consistent with methodologies to determine RME exposures and risk Arcadis considered that not all construction work will be on PG roads due to possible alternate construction methods and maintenance work for the vast network of existing roads.

The value used in the Risk Assessment represents a portion of industry tenure spent constructing roads: 80% of 25-year worker tenure recommended by USEPA (2014) constructing roads = 20 years; 25% of road construction time spent using PG = 5 years. Based on the employment statistics provide above the actual exposure is likely to be much less than 5 years.

15. USEPA: The TFI Risk Assessment for the Truck Driver scenario uses a density of 1.12 gm/cm3 for phosphogypsum in the truck. U.S. Department of Transportation, Federal Highway Administration, Research and Development Turner-Fairbank Highway Research Center, User Guidelines for Waste and By-Product Material in Pavement Construction, FHWA-RD-97-148 gives a specific gravity range from 2.3 – 2.6 gm/cm3 (p. 19-6), and in a second location states, "specific gravity of solids ranges from 2.30 to 2.50, with an average in the 2.35 to 2.40 range." (p. 19-14). TFI assumes that loose PG in the truck will be about half the density of that identified in the FHWA document. PG that is excavated and loosely placed in a truck will certainly have a higher porosity, but what is the basis for assuming this specific value?

Arcadis: The specific gravity values of 2.3 to 2.6 (unitless) are common in literature about PG. For example, Chang and Mantell 1990[20], reported the average specific gravity values of seven Florida

---

[19] Burmaster, David E., 2000, *Distributions of Total Job Tenure for Men and Women in Selected Industries and Occupations in the United States, February 1996*. Risk Analysis, Vol. 20, No. 2, 2000.
[20] Chang, Wen F., and Mantell, Murray I., 1990. Engineering Properties and Construction Applications of Phosphogypsum, University of Miami, Phosphate Research Institute, ISBN No. 87024-328-4.

sources of PG varied between 2.33 and 2.43. The specific gravity values of this magnitude however related to particle specific gravity and ignores the porosity / void space in the bulk material. The same reference reports the maximum dry bulk density of PG following compaction to range between 90.3 to 102.7 lb/ft^3. This compacted bulk density converts to 1.4 to 1.6 g/cm^3. For material excavated and loaded into a truck a swell factor of 20% - 30% is not uncommon for materials such as soil, sand or gravel. For the Risk Assessment the density of the PG in the truck can be supported using a bulk density of 1.4 g/cm^3 with a swell factor of 25% (1.4/1.25) resulting in PG density during transport of approximately 1.12 g/cm^3.

As previously indicated, density is an important factor in assessing potential doses arising from road building. The in-place post compaction density of PG in road base will be specified along with other physical characteristics by the appropriate local, state or federal highway authority. The densities used in the current (2019) risk assessment are considered appropriate for the purpose of risk assessment.

16. USEPA: Assumed inhalation rates may need further justification. As stated in the TFI Appendix 2 (p. 2-11): "The RESRAD default inhalation rate of 8,400 cubic meters per year (m3/yr) was used for the nearby resident receptor. A higher inhalation rate of 11,400 m3/yr was assumed for road construction workers and utility workers. This value was the RESRAD version 6 default for industrial workers and assumes an hourly rate of 1.3 m3/hr." When 11,400 m3/yr is multiplied by the fraction of time spent outdoors (on site) the result is the Road Construction Worker annual inhalation rate of 2,622 m3/yr. This value is about 9% larger than the worker inhalation rate used by the International Commission on Radiation Protection (Guide for the Practical Application of the ICRP Human Respiratory Tract Model, 2002). However, compared to the EPA Exposures Factors Handbook (EPA 2011) Tables 6-1 and 6-28, the inhalation rates for moderate and heavy activities, the RESRAD rate of 1.3 m3/hr is lower than the low end of the range provided for EFH worker inhalation rate. The low end of the range is 1.6 m3/hr and the high end is 4.8 m3/hr, several times higher than the RESRAD rate.

Arcadis: RESRAD exposure parameters for workers were applied where available. Considering the exposure duration of a full day, it is expected that a moderate inhalation rate would be more realistic of the overall inhalation rate as heavy activities would not be continuous throughout the day. The values in Table 6-28 of EPA Exposure Factors Handbook (EPA 2011) ranging from 1.6 m^3/hr for the low end of the moderate activity level, which is for adult females, to 4.8 m^3/hour for the high end of the heavy activity level, which is for adult males, is based on information included in a dated guidance document (i.e., EPA 1985).

More recent studies are referenced in the Exposure Factors Handbook (EPA 2011), several of which were specifically conducted on workers or more specifically construction workers. One study of "high risk" populations exposed to ozone in the Los Angeles area found a mean inhalation rate of 0.78 m^3/hour for healthy adults and a mean of 1.5 m^3/hour for construction workers during a 10-hour work shift (Linn et al. 1992). Linn et al. (1993) studied inhalation rates of construction workers (i.e., laborers, iron workers, and carpenters) during work and break times based on a relationship to heart rate and determined a mean inhalation rate of 1.68 m^3/hour with a standard deviation of ± 0.72. However, estimates of extremes (e.g., 99th percentile) were outside the calibration range of the model and would not be appropriate for an RME. Lastly Allan et al. (2009) determined mean inhalation rates of 1.4 m^3/hour for male construction workers and 1.25 m^3/hour for female construction workers based on probability density distributions generated using Monte Carlo simulation. Therefore, the inhalation rates used which are based on RESRAD defaults are appropriate mean estimates.

While upper percentile estimates may represent a relative extreme, those assumptions are not appropriate for a reasonable maximum exposure scenario. Regardless, using an inhalation rate up to 3 times higher resulting in inhalation doses 3 times higher would still add relatively little to the overall dose and risk as the inhalation route of exposure results in a dose that is orders of magnitude less than external radiation and an order of magnitude or more less than ingestion exposure.

17. USEPA: It is difficult to evaluate the appropriateness of the worker exposure parameters TFI used in Appendix 2, in part due to a lack of detail in discussion of road base and pavement construction process, procedures, and equipment. Page 3-2 states "it was assumed the road construction worker moves around the surface of the road and the direct dose was calculated as the average of the dose at the road center and at the edge of the road." Would different workers have different roles, such as walking directly behind machinery versus walking on the road shoulder? What would happen to the doses if this ratio was changed, such as 75% middle of the road/ 25% edge?

Arcadis: The assumption of the construction worker exposure at both the center of the road and the edge of the road approximates the expected movement of a worker throughout a full workday. Shifting this parameter to the extreme of working 100% of the time in the center of the road would provide a minor increase in the exposure and risk.

As shown in the calculations in a previous question above, assuming the worker spends 100% of the time in the center of the road provides an annual exposure of 28 mrem/yr. This is a 27% increase from the 22 mrem/yr exposure reported in the risk assessment, based on 50% in the middle of the road and 50% along the edge of the road, but makes no change to conclusion that the risk is significantly below 3:10,000. But it is unrealistic to assume a work stands in one spot all day. If a worker did so, he or she would have a very low inhalation rate.

ECONOMIC ANALYSIS OF PHOSPHOGYPSUM REUSE

The Fertilizer Institute

Submitted by:

Policy Navigation Group

December 2019

EXECUTIVE **SUMMARY**

Policy Navigation Group (PNG) conducted this analysis on behalf of The Fertilizer Institute (TFI) to esti mate the potential regulatory cost savings of changes that would expand the use of phosphogypsum (PG) to include road construction. This application is in use tn Europe and elsewhere, but currently is precluded in the U.S. due to U.S. Environmental Protection Agency (EPA) regulatory restrictions. This section outlines the main steps we undertook to perform the analysis and summarizes the economic benefits of using PG for road construction.

Outline of Steps in Analysis

In the analysis that follows, we take these steps to estimate the potentf al cost savings of using PG for road construction:

> Identify the costs to manage PG currently in stacks located at numerous sites. These include the costs of land for the stacks, the costs to transport PG to the stacks, the costs of managing water at and preserving the physical stability of the stacks, and the costs to close the stacks.
>
> Assess scenarios for PG reuse in road construction in the near future. We assume that PG reuse will start modestly and growover time. Given market uncertainty over the potential demand for PG, we estimate the savings for a lower-bound and an upper-bound scenario; any savings are expected to be within this range. Due to transportation costs and the availa bility of substitutes, we assume that the PG reuse market faces natural limits and largely is confined to locations relatively close to current plants and stac ks.
>
> Estimate the cost savings from PG reuse. Companies can incur savings in PG manage me nt costs if they send PG t o be reused (stack manage ment savings from the regulat ory reform). Since the stack management savings from the regulatory reform frees up the labor, capital, and physical land needed for PG stack management, in competit ive markets some of these savings are passed through to the companies• customers and purchasers of PG for reuse. Ultimately the savings pass through to the state and local highway departments, companies' shareholders, companies• workers, farmers and other purchasers of fertilfzer, and other households and firms.[1] For this reason, these cost savtngs are atso the social benefits of the reform. They are also the deregulatory savings from an EPA action to allow reuse for road const ruct ion.

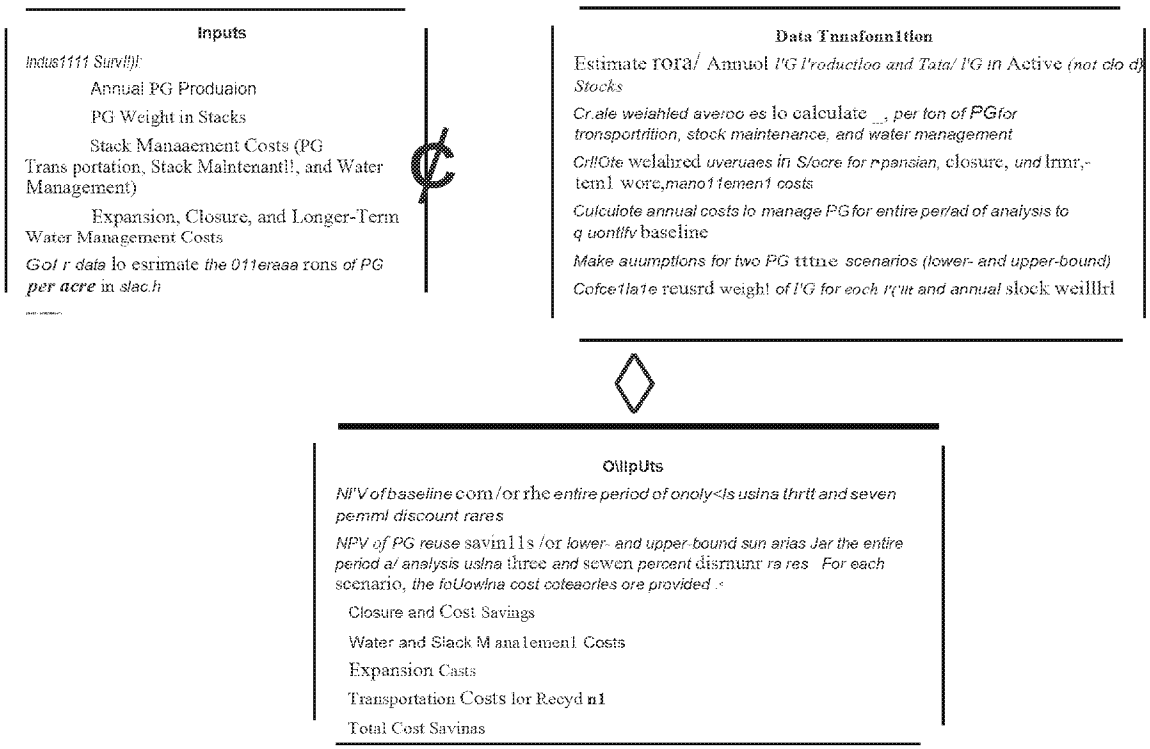
Figure ES-1 summarizes the key inputs used in the analysis and shows the data transformati on and resulting outputs.

---

[1] In this analysis, we only consider the direct economic impact of the reform. There will be indirect and induced economic impact of the reform as fertilizer customers have lower input costs and can gain market share from imports and as workers spend their greater compensation on consumer goods and services. These gains then induce additional economic impact such as higher spending by vendors to the fertilizer ,e.urchaser and the workers.

ED_005285_00000990-00002

Figure ES-1: Diagram Summarizing Analytical Approach for Proj ect [2]



Summary of the Regulatory Savings

The analysis produced by taking the steps above provides a clear picture of the cost savings of using PG for road construction. Table ES-1 presents the baseline costs to manage PG from 2020-2042, which range from $1.3 billion to $0.88 billion using three and seven percent annual discount rates. Table ES-2 summarizes the cost savings from PG reuse for the two reuse scenarios; it shows that the total net present value (NPV) savings range from $37 million to $52 million for the lower-bound scenario and from $110 million to $160 million for the upper-bound scenario, using discount rates of seven and three percent, respectively.[3] We use three and seven percent discount rates to calculate the results from this analysis, as directed by U.S. Office of Management and Budget Circular A-4.

[2] We use three and seven percent discount rates to calculate the results from this analysis, as directed by the U.S. Office of Management and Budget's Circular A-4.

[3] The results presented in this analysis are rounded to two significant figures. Due to rounding, total values in the tables mat notsum.

ED_005285_00000990-00003

Table ES-1: Net Present Value (NPV) of Baseline Costs to Manage PG

CATEGORY	NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Baseline Costs	1, 300	**880**

Table ES-2: Net Present Val ue (NPV) of Cost Savings from PG Reu se

COST CATEGORY [4]	LOWER-BOUND SCENARI O	LOWER-BOUND SCENARIO	UPPER-BOUND SCENARIO	UPPERBOUND SCENARIO
	NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	**NPV USING A 7%** DISCOUNT RATE (IN $ MILLIONS)	NPV USING A 3% DISCOUNT RATE (IN $ MILLIONS)	NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Cl osure Cost Savings	11	11	33	32
Water and Stack **Management Costs**	22	13	65	37
Expansion Cost s	**19**	13	57	**38**
Total Cost Savings	**52**	37	**160**	110

In summary, expanding the use of PG in road construction is expected to result in savings not only to PG produ cers, but also to numerous users of PG and workers, sha r eho l d ers, and customers of fertilizer firms.[5]

[4] Transportation sa vings are omitt ed from the results shown in this table as they amount to zero dollars. Transportat ion cost from the stack to the const ruction site is not incl uded because it is assumed t hat the cu stomer would pay for this t ransporta tion as part of the road construction cost .

[5] Savings to users of PG, workers, shar eholders, and customers of fert ilizer firms are not evaluated in this economic ana lr sis.

INTRODUCTION

Policy Navigation Group (PNG) conducted this analysis on behalf of The Fertilizer Institute (TFI) to estimate the potential regulatory cost savings of using phosphogypsum (PG) for road construction, an application currently in use in Europe and elsewhere. This section provides a summary of the industry, followed by a description of PG, its production in the U.S., and U.S. Environmental Protection Agency (EPA) PG requirements. It then touches upon PG reuse options and scenarios before concluding with a description of how the remainder of the report is organized.

Summary of Industry

Phosphate rock is predominantly used to produce phosphoric acid, which is primarily used to manufacture fertilizer. The U.S. was previously the largest producer of phosphate rock and leading exporter of phosphate fertilizer, until China increased its production in 2011 and surpassed the U.S. as lead world exporter in 2014.[6] Currently, the U.S. is the second-largest consumer of phosphate rock (consuming 29 million metric tons (MT)) and the second-largest producer of phosphoric acid (producing 14 million MT).[7] Domestically, phosphate rock ore is mined primarily by five firms in four states - with 80 percent of the mining occurring in Florida and North Carolina - to produce approximately 27.1 million tons of marketable product.[8] After being mined in open-pit mines, phosphate rocks are treated, washed, and dried in rotary kilns.[9] The ore is then finely ground and converted into a soluble form through either a wet or dry process. In the U.S., facilities exclusively use a wet process that digests the phosphate rock in a reaction vessel with sulfuric acid, producing both phosphoric acid and a largely calcium sulfate byproduct known as PG.

Total worldwide production of PG is estimated between 100-280 mega tons per year.[10] About 85 percent of world PG production is discarded or stored. The remaining 15 percent of worldwide production is reused as soil amendment, agricultural fertilizer, and set controller for cement and building materials worldwide.

Around the world, PG is used in a range of applications, including:[11]

- In fertilizer for agricultural soils;
- In backfill and road-base material for roadway and parking lot construction;
- As an additive to concrete and concrete blocks;

- In wallboards;
- In mine reclamation; and
- In the recovery of sulfur.

Prior to the 1992 EPA restrictions on its widespread reuse, PG was critical to the peanut industry as a soil amendment valued for its fertilizer properties across Georgia, North Carolina, Virginia, and Alabama, and on farms across the southeast that grow tobacco, corn, small grain, and sugar cane.[12] As a large peanut producer, Georgia was the largest PG consumer. States such as California also used PG for soils growing citrus, almonds, vegetables, and tomatoes. In these and other locations, PG was widely used, since it had been shown to be a beneficial source of sulfur in improving crop yields.

Description of Phosphogypsum

PG byproduct is filtered from the phosphoric acid and transferred as a water slurry to be stored in open-air areas called PG stacks. The slurry is pumped atop the stack, where an engineered "gypsum stack and pond" is formed. Water impounded from PG stacks is reused in the overall wetting process. Closing PG stacks involves complex engineering, including placing high-density polyethylene liners as caps to prevent rainwater from infiltrating and reduce stack water from percolating out from the bottom of the stacksn.

Reuse Options and Scenarios

Other countries, most notably Japan and some nations in Europe, have and currently reuse some PG for specified uses that have included road base material, cement, wallboard, and other building materials. [14]

Road Base

Prior to EPA restrictions on its use in 1992, PG was mixed with ash, sand, gravel, or cement, and was used as a base for roads, parking lots, and storage areas to help control setting times, counteract shrinkages, strengthen cement products, and create resistance to sulfate etching.[15] Numerous publications are available detailing these uses. The following are some examples of how PG was used in Texas, Florida, and North Carolina: [16]

- In Pasadena, Texas, PG was mixed with fly ash and cement for road base at five sections of city streets in La Porte, Texas.
- In Polk County, Florida, PG was mixed with granular sand to construct 2.4 kilometers of road base, surfaced with asphalt.

[16] U.S. Environmental Protection Agency.

ED_005285_00000990-00009

- In Columbia County, Florida, two miles of road base was constructed with 100 percent dehydrated PG and varying mix ratios of PG and sand. The road base was also surfaced with asp ha lt.
- In North Carolina, PG was comme rcially used as a fill and sub-base for roads in swampy areas.
- In Ba rtow, Florida, the Florida Instit ute of Phosphate Research used a mixt ure of PG and concrete to pave two thousand yards of driveway and parking areas.

Ce me nt and Concrete Aggregate

PG also has been used to manufacture building materials, includi ng concrete and cement aggregates, particularly outside the U. S.[17] Additionally, it can be used more extensively in building ma te rials, including ce ment , wallboard, ferrocement panels, plasterboard panels, partition blocks, plaster, tfles, artificial stone, and glass ceramics. [18]

Several studfes have demonstrated that PG can help prolong concrete setting times.[19] The increased setting time supports long-term concrete strength. Incremental initial and final setting times increase with increasing PG content. Using PG as a retarder agent is particularly beneficial in civil engineering work involving casting in hot weather, casting retaining deep walls, and casting mass concrete and repair ele me nts , for example.[20]

I ncluding PG in cement also has the benefit of reducing density, increa si ng chemical resistance, increasing free resistance, and increas ing fire resistance. [21] As such, PG has the potential to be used as a partial substit ute for materials aggregate in concrete.

Organization of the Report

The rest of the report discusses current PG manage me nt costs and incurred savings from PG reuse, showing how we developed scena rios for PG reuse and estimated the cost savings for these scenarios. Since the regulatory change frees up the labor, capital , and physical land needed for PG stack manageme nt , these savings are also the social benefits of the regulatory reform.

CURRENT PG MANAGEMENT COSTS AND COST SAVINGS FROM PG REUSE

Introduction and Methodology Overview

This section provides an overview of current PG production and PG stored in stacks; details and quantifies the current costs of PG management; describes and quantifies the potential short- and long-term cost savings if a percentage of currently produced PG is reused for road construction; provides baseline and PG reuse scenarios to illustrate several key points; and presents the variables, assumptions, and methodology used in all the above.

A survey was conducted with members of TFI in July 2019. The survey included questions on current PG production; weight of PG stored in active stacks; and costs to transport, manage, expand, and close stacks. The survey was conducted, compiled and summarized by an independent party who removed identifying information before data was provided to PNG for analysis. The survey questions are provided in Appendix 1.

Using the survey information, we estimate averages for current production, average weight of PG stored in active stacks, and costs. With these estimates, we calculate the current costs of managing PG - the baseline costs. Then, we create two scenarios (lower- and upper-bound) to estimate the cost savings if a percentage of the PG produced is beneficially reused.

The timeline of the analysis is from 2020 to 2042. All future values are discounted using a three and seven percent discount rate and presented in 2019 dollars. [22] The values in the tables are rounded to two significant digits. Therefore, the totals shown in some tables may not sum exactly. We only consider active PG stacks for this analysis, as according to information received from the industry, it is unlikely that PG from closed stacks would enter the reuse market.

PG Production and Annual Growth Rate

Survey participants provided annual PG production data (in tons per year) for 2016, 2017, and 2018 for nine active stacks. Data was provided by the largest PG producers in the U.S., but it does not include all active stacks and PG producers in the country. To account for variability across stack data (both, on annual basis and by stack), we calculate weighted averages. To calculate the weighted annual production rate, we estimate the average growth (in tons) for each stack from 2016 to 2017 and from 2017 to 2018. Then, we estimate the corresponding weighted average growth rate for each period (from 2016 to 2017 and 2017 to 2018). We derive industry representative weighted averages by weighing each stack's size by its proportion of the sum of the size for all the stacks in the survey.

To estimate the annual production of PG available for reuse, we calculate the weighted average across all the active stacks. For this estimate, we quantify the multi-year average per active stack (from 2016 to 2018) and then the weight of the multi-year average per stack in relation to all the active stacks. This gives a weighted average annual production of PG of 5.1

---

[22] U.S. Department of Labor. Bureau of Lal:>or Statistics, "CPI Inflation Calculator."

ED_005285_00000990-00011

million tons. We multiply this value by nine stacks to obtain a weighted annual total U.S. production of 46 million tons of PG.

For this report, we assume that PG production in the U. S. will not experience growth in the timeline of the analysis - that it will remain at the same level as in the baseline. We make this assumpt ion because information received from the industry for this analysis forecasts no growth. Furthermore, the survey data spans only a three-year period and varies by company and year, rendering it difficult to determine any long-term trend in terms of growth. We note that this assumption is in line with market reports from Europe, which show near-zero growth for PG production between 2012 and 2017.[23]

Table 1 summarizes the PG productio n data used for the analysis.

Table 1: PG Production

ITEM	AMOUNT
Weighted Average of Production , Per Year, Per Stack	5,100,000 tons
Total Annual Production of PG	46,000,000 tons

PG Stored in Stacks

For the nine active stacks discu ssed in the previous subse ction, we received the approximate amount of PG stored in each. For eight of the nine stacks, the weight was provided in tons. For one of the stacks, we were provided the volume in cub ic yards, which we converted into tons using a density factor of 1.9 tons per cubic yard.[24]

The surveyed companies also provided informat ion for inactive stacks, as PG from inactiv e stacks may be used.

Using the survey information, we add the tota l weight in both active and inactive stacks. Additionally, we calculate the weighted average tons for both types of stacks by creating we ights per stack (that is, how much each stack represents of t he total in the corresponding catego ry). These weights are further used to est f mate the average costs per ton (see subsection below).

Figure 1: Projected New PG Production and PG in Stack s[25]

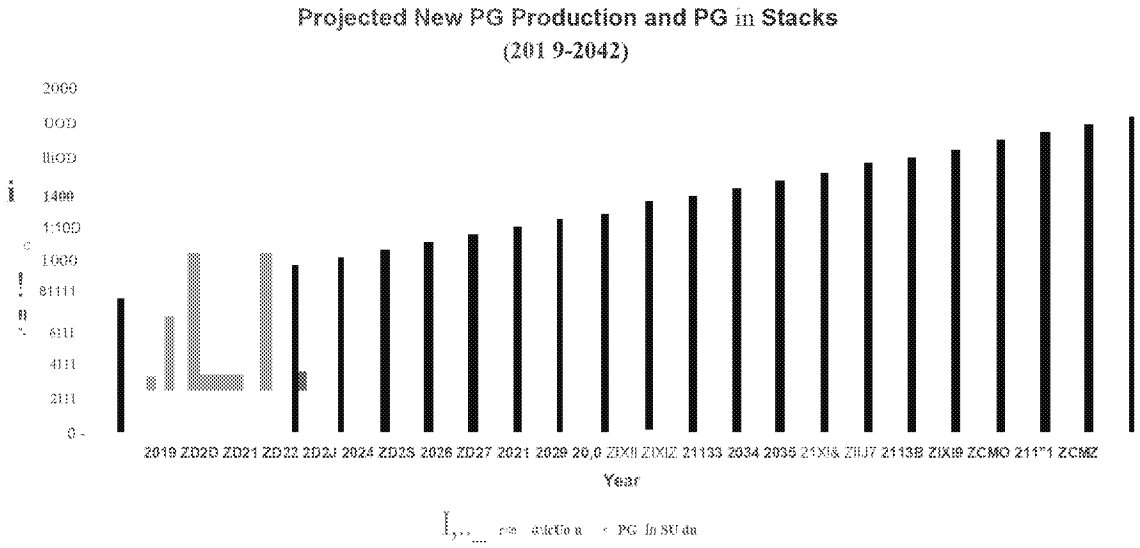

Table 2 summarizes the PG stored in stacks and Figure 1 shows both the PG in stacks and the projected new production of PG. While the period of analysis is 2020-2042, Figure 1 includes data for 2019, as the PG in stack value for 2020 must include the weight for 2019.

Table 2: PG in Stacks

ITEM	ACTIVE STACKS	INACTIVE STACKS	TOTAL
Total PG Stored (milllon **tons)**	517	217	734
Weighted Average Per Stack (mlilllon **tons)**	69	65	NIA

Costs to Manage PG

In response to the survey, companies provided annual costs per stack for the following categories[26]:

- Transportation costs - costs to transport PG from the plant to the stacks
- Stack maintenance costs - labor, monitoring, inspectton, and reporting costs
- Water management costs - costs for water balancing and water treatment

[25] Figure 1 reflects the current baseline and does not show the PG reuse scenarios discussed later in the analysis.

[26] The cost information was provided by stack and was not tied to PG production levels.

ED_005285_00000990-00013

We then use the weights calculated for PG production and PG stored in stacks (see previous subsections) and apply those to the survey data's cost per stack. For the transportation costs, we use the weights for PG production, as tr ansportation costs are i ncurred in transporting PG from the plant to the stacks; once the PG i s in place at the st ack, no additional transport ati on costs are assumed to be incurred. For stack maintenance and water management costs, we use the weights corresponding to PG stored in stacks and apply them to the whole amount of PG stored in a stack. Then, we calculate the weighted average cost per category. To do this, we multiply the corresponding weight by the cost per year per st ack, add those product s, and divide the resulting sum by the sum of the weights used. Finall y, we obtain the average cost per ton by dividing the weighted average by the number of tons per cost category.

The volume of water generated and treated (the water management volume) can be affected by factors such as weather condi tions, the manufacturi ng process, and the age of the PG. The major climate consideration would be variability in precipitation among different geographic regions. While water management volumes would decrease over time due to reduction in size and number of PG st acks, it would not completely disappear. As with alt new sustainability strategies, innovation and synergies may lead to additional water management reductions as yet to be determi ned .

Thus, in practice, the stack water generation and treatment volumes can vary signi fi cantly by the location and by the age of the stack. Whi te we asked r espondents for typical, current values for wate r management costs, we are unaware if respondents provided data that represents average climate conditions and PG aging.

Table 3 provides the weight of PG in active stacks, the weighted average costs and the cost per ton for the three cost categories.

Table 3: Weight of PG in Active Stacks and Costs

ITEM	TRANSPORTATION COSTS	STACK MAINTENANCE COSTS	WATER MANAGEMENT COSTS
Weighted Average ($ millions)	7.2	6.8	7.4
Total Tons of PG in Category (mUtion **tons)**	8.3	570	380
Average Cost Per Ton ($) [27]	0.87	0.012	0.02

[27] Average cost per ton is obtained by dividing the weighted average by total tons of PG. For example, for transportatfon costs 7.2/8.3 =$0.87. Note that values in the tab le are rounded to two significa nt figures as noted ea rlier in the analysis. As a result , total values in table may not sum exactl y.

ED_005285_00000990-00014

Other Stack-Related Costs

Survey participants indicated that, in addition to transportation, water management, and stack maintenance costs, there are other long-term costs associated with PG stacks - stack closure costs, water inventory costs, and stack expansion costs. These costs are expected to be incurred in the next five years (between 2020 and 2024).

To avoid providing identifiable information, the surveyed companies provided costs for those long-term categories in dollars per acre of PG stack. In some instances, they provided a lower- and upper-bound estimate for the category. Also, some companies reported zero costs for the category or reported them as part of another category. For this analysis, we create upper- and lower-bound estimates per category, then calculate the middle-point value. Table 4 outlines these costs.

Table 4: Long-Term Costs of PG Management

ITEM	STACK CLOSURE COSTS	WATER INVENTORY COSTS	STACK EXPANSION COSTS	TOTAL	UNIT
Average-Lower Bound	**91,000**		**220,000**	330,000	$/acre
		23,000			
Average-Upper Bound	100,000		240,000	360,000	$/acre
Total **Average**	96,000	23,000	230,000	350,000	$/acre

Cost Summary

Table 5 summarizes the cost savings due to PG reuse. The most significant savings occur from deferring stack closure and expansion, which together represent almost $350,000 per acre of PG. Since one stack can contain more than 70 million tons of PG, the cost savings of reusing PG are significant.

ED_005285_00000990-00015

Table 5: Sh ort - and Long-Term Costs of PG Management

ITEM	COST	COST TYPE	UNIT
Transportation Costs	0.87	Short -term	$/ton

Cost Savings from PG Reuse Scenarios

Baseline Scenario

In this scenari o, we quanti fy the current costs of managing PG at phosphoric acid plants. As ou tlt n ed in Table 1, the weighted annual PG production is approximately 46 million tons. Figure 1 outlines the total amount of PG expected to be produced per year from 2020 to 2042. It also presents the amount of PG expected to be stored in stacks during that same period. Given the current regulatory restrictions on using PG, this scenario assumes that all new PG produced is put into stacks.

To estimate the costs for the baseline scenario , we first mul tiply the weighted annual production of PG by the transportation costs per ton ($0.87). We then multiply the weight of PG stacked by the sum of stack maintenance and water management costs per ton of PG ($0.03). Finally, we add the transportati on, stack maintenance, and water management costs for the entire period and calculate the net present value (NPV) using discount rates of three and seven percent.

PG Reuse Scenarios

Lower-Bound Scenario

In this scenario, we assume that a percentage of PG produced annually is reused. When PG is reused rather than put into st acks, PG producers incur savings in water management costs, stack maintenance costs, and long-term savings for the amount of PG reused; the only costs they incur are those associated with transport of PG from the facility to the construction site. The NPV of these cost savings minus the transportation costs to the construction site (at discount rat es of three and seven percent) are the results for this scenario.

This scenario assumes that five percent of current PG production is reused in each year in 2020 and 2021, 7.5 percent is reused each year in 2022 and 2023, and 10 percent is reused

ED_005285_00000990-00016

in 2024 (see Table 9). Between 2025-2042, the assumed reuse percentage remains at 10 percent. We arrive at this representative reuse scenario by assuming that the PG reuse market will start slowly due to the availability of competing products that already have market share and may be sold through longer-term contracts. Additionally, since PG has been off the market for almost 20 years, this assumption accounts for the idea that it may take PG sellers some time to convince potential customers of PG's beneficial qualities. With these assumptions in place, we calculate water management, and stack maintenance savings by multiplying the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03 (see Table 6).[28]

Upper-Bound Scenario

In this scenario, we assume that PG suppliers will offer favorable pricing relative to competing products, effectively promoting greater PG reuse that grows robustly over time. Specifically, we assume that 10 percent of current PG production is reused in 2020, 15 percent is reused in 2021, 20 percent is reused in 2022, 25 percent is reused in 2023, and 30 percent is reused from 2024 (see Table 6). As in the lower-bound scenario, we arrive at this representative reuse scenario by assuming that the PG reuse market will start slowly due to the availability of competing products that already have market share and may be sold through longer-term contracts, and that it may take PG sellers some time to convince potential customers of PG's beneficial qualities. With these assumptions in place, we calculate water management, and stack maintenance savings by multiplying the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03 (see Table 6).

[28] Water management and stack maintenance savings are recurrent annual costs. Therefore, they are calculated over the sum of PG reused in a given year plus PG reused in the previous years. For example, for the upper-bound scenario in 2022, water management and stack maintenance savings are calculated over 20.7 tons (sum of amount reused from 2020-2022).

Comparison of Reuse Scenario versus Current Demand for Road Construction

We compare this reuse scenario to the size of local markets as one measure of the reasonableness of the scenario. To validate that our assumptions on PG reuse are feasible given the overall size of the road aggregate market, we contacted the Florida Department of Transportation. We selected Florida as a representative construction market since a majority of the nation's PG is generated in Florida.

Due to the high cost of transporting PG to be used in road construction, we consider that the potential demand for PG is limited to within one day's hauling of the production location, or approximately 200 miles. Both the lower and upper bound scenarios of PG reuse are well within Ronda's projected future demand for aggregate for road construction.

Stack Closure Costs

We assume that by reusing a percentage of current production, PG producers will be able to defer stack closure costs. Thus, less PG would need to be stored in stacks, and current stack capacity would last longer. However, it is difficult to predict the number of stacks that may be closed - or expanded - in the period of analysis (and thus estimate the potential cost savings from those deferred stack closures). We believe this to be the case based on insights provided by survey respondents, which suggest that stack closure and stack expansion decisions require long-term strategic planning and are subject to company-specific PG production forecasts and stack capacity.

Recognizing the limitations of generalizing from company-specific conditions to a industry-representative average, in this analysis, we start by assuming that stack closure costs are deferred until 2039 for both the lower- and upper-bound scenarios. The assumption that a stack is closed in 2039 is consistent with historic stack closure reports, as stacks are generally closed after reaching a certain acreage. The purpose of this estimate Is to show the potential savings that could arise from deferring stack closure due to PG reuse. For these estimates, the closure cost per acre of PG corresponds to the sum of the water inventory management and stack closure costs ($120,000). Closure occurs in 2039, but the period of analysis covers years until 2042 to allow for the completion of active stack closure activities.

The weight of PG in the survey is provided in tons, while the long-term costs are provided in dollars per acre. Therefore, we next need to estimate how much PG is generally found in one acre. For this estimate, we use a dataset with stack data for Florida. [29] This dataset has information on stack area and length. We assume that all stacks in the Rorida dataset are 100 meters in height, have a rectangular base, and have a side slope of 1:3. To estimate the stack width, we divide area by length. Then, we calculate the volume per stack and multiply that volume by an assumed density of PG of 2.3 g/cm^3. [30] (The approach to estimate the stack

[29] State of Florida, "Florida Gypsumstacks."

[30] U.S. EPA, Region 4, Superfund Division, "Engineering Evaluation/Cost Analysis: Closure of the East Gypsum Stack and North Ponds, Mississippi Phosphates Corporation Site, Pascagoula, Jackson County, Mississiee i."

ED_005285_00000990-00019

volume was derived from EPA and Florida Department of Environmental Protection sources. [31]) Finally , since the Florida dataset uses data in metric units , we convert square meters into acres. Thus, we conclude that one acre contains approximately 850,000 tons of PG. We then divide the tota l tons of PG reused in 2039 for the lower- and upper•bound estimates by 850,000 to obtain the equivalent number of acres, multiply it by the actual cost per acre ($120,000), and present the NPV using three and seven percent discount rates.

In t his re port, based on the estima te d reused PG from 2020-2039, we assume that a PG stack of 97 acres is closed in 2039 for the lower-bound scenario and a PG stack of 290 acres is closed in 2039 for the uppe r-bound scenario.

Stack Expansion Costs

To estimate the potential cost savings from stack expansion, we first divide the weight of PG reused per yea r by 850,000 to conve rt it into acres. We then multiply the resulting quotient by $230,000, which is the cost to expand one acre. Fina lly, we discount the costs using three and seven percent rates.

Stack Maintenance and Water Management Costs

To est imate the pote ntial cost savings from stack ma inte na nce and water manag ement , we first multiply the sum of the annual weight of PG reused (in tons) plus the weight of PG reused in previous years by $0.03. We then calculate the NPV for the enti re period of analysis using three and seven pe rcent discount rates .

Transportation Costs to Reuse Location

We assume that PG transportation costs are essentially the same as the cost of transporting alternative materials; therefore , from a social cost perspective , there is no marginal savings by transporting PG or another aggregate. This leads to the conclusion that there are no potential benefits related to savings from transporta tion costs. Thus, transportation costs are not shown in Table 9 conside ring that they are zero.

Table 7 provides the key assumptions for PG reuse used in the analysis .

Table 7: Key Assumptions for PG Reuse Scenario

ITEM	LOWER-BOUND SCENARIO	UPPER-BOUND SCENARIO
PG reused In 2020	5% of annual production	1 0% of annual production
PG reused In 2021	5% of annual production	15% of annual production
PG reused In 2022	7.5% of annual production	20% of annual production
PG reused In 2023	7.5% of annual production	25% of annual production
PG reused in 2024	10% of annual production	30% of annual production
Year in which stack closure occurs	2039	2039
Conversion rate for PG (tons Into acres)	850,000	**850,000**

Results of Cost Savings from PG Reuse

Table 8 shows the total NPV of baseline costs associated with managing PG stacks, which range between $0.88 billion and $1.3 billion at seven and three percent discount rates, respectively.

Table 8: NPV of Baseline Costs to Manage PG

CATEGORY	NPV USING A 3% DISCOUNT RATE (IN$ MILLIONS)	NPV USING A 7% DISCOUNT RATE (IN $ MILLIONS)
Baseline Costs	**1,300**	**880**

The total NPV of cost savings between 2020-2042 is presented in Table 9. It shows savings associated with PG reuse ranging between $37 million and $52 million for the lower-bound scenario and $110 million and $160 million for the upper-bound scenario, using seven and three percent discount rates, respectively. It also presents the estimated cost savings for stack closure, water and maintenance management, expansion, and transportation costs. The largest savings result from the deferred stack expansion costs, with the second-largest savings a result of deferred stack closures.

ED_005285_00000990-00021

Executive Order 13771 Deregulat ory Savings

Under E.O. 13771, EPA's action to allow PG to be reused as a road construction material would constitute a deregulatory action and would generate savings that could help EPA achieve its regulatory allocation.

Assuming that EPA either changes its existing regulation to allow a regulatory exemption for PG reuse in road construction or gives a one-time , broad approval of a petition for road construction reuse, EPA's action would constitute a deregulatory action under E.O. 13771. The Office of Management Budget's i mplementingmemor andum for E.O. 13771 draws the distinction between routine regulatory actions and one-time actions that produce on-going savings. Agency actions that require regular agency approvals - e.g., quotas, permits - are not deregulatory actions under E.O. 13771. However, if EPA's approval of PG petitions does not require further approvals, is not conditioned on satisfying reporting requirements, and is broadly applicable to PG producers, it would likely qualify as a deregulatory action. EPA then could count it as part of meeting E.O. 13771 's ratio of one deregulatory action for every two regulatory actions.

The action would also generate deregulatory savings. Under E.O. 13771, agencies are granted a regulatory allocation for each fiscal year. [33] The regul atory costs of significant economic regulatory actions and the deregulatory savings must add up to less than the agency's allocation. Agencies must align the savings and costs in the same fiscal year; in this case, the deregulatory savings from allowing PG reuse occur in future years. Table 10 gives the

[32] Transportation costs are omitted from the table as they are zero. Potent ial revenue obtained from selling PG is not estimated in this report.
[33] "Executive Order 1Jn1 of Ja nuary 30, 2017, Reducing Regulat ion and Controlling Re gulato ry Costs."

ED_005285_00000990-00022

estimated annual savings for the next five years, an illustrative period to demonstrate how savings increase in the near-term before reaching a relatively constant value.

Table 10: Estimated Cost Savings from 2021-2025

TOTAL COST SAVINGS (IN MILLIONS $)	2021	2022	2023	2024	2025
At 3 and 7 Percent Discount Rate	1.1-3.2	1.7-4.5	1.8-5.8	2.4-7.2	2.6-7.7
At 7 Percent Discount Rate	1.1-3.2	1.7-4.5	**1.8-5.8**	2.4-7.1	**2.6-7.6**

Summary

In summary, the analysis shows that the potential regulatory cost savings of changes that would allow the reuse of PG ranges between $37 million and $160 million. These results represent the NPV of savings for the period of analysis (2020-2042). These results strongly support the reuse of PG for beneficial applications such as road construction in the U.S. - applications already permitted and used in Europe and elsewhere. Additionally, they support the idea that using PG for road construction offers the possibility of significant savings not only to PG producers, but also to state transportation agencies to the extent they replace a percentage of the aggregates currently used for road construction with PG.

Dear Jon, Dan, and Tom:

I created a document page with the supporting materials that will appear in the Docket upon publication. It includes a signed copy of Administrator Wheeler's letter, as TFI told Lee they had no problem with our putting on the website. Please review the page to ensure I got everything right, and provide me with any edits. We need to publish this tomorrow morning to answer the press inquiry due at 11 AM. (It will enable us to quickly answer or even avoid further inquiries).

The page link is below. You will need to log-in with your LAN ID and password.

Ex. 5 Deliberative Process (DP)

One document is missing: I need RPD's Review of the Risk Assessment. Please provide that to me as soon as it ready for release.

Thanks for all your help with this.

Hi Joe,

One more option if you think it would be helpful, we could try to convert the PDF to a word document if you'd like for people to comment directly in the document. This generally works well, but there are a few snags that I've ran into before that would prevent us from being able to do this. This is another thing we can talk about during today's admin call if you think it would be something worth looking in to.

Thanks!
Stefanie

Subject: Responses to latest TFI documents

I've uploaded the documents that TFI sent us to a folder on Sharepoint. I tried to set it up so that you could comment directly on the submissions, but sharepoint for now doesn't allow commenting on pdfs (we would have to add comments and then re-upload each individual commented version separate). For now, I've created two word documents: a general questions document, and a modeling specific questions document. Please add each of your comments/questions under a header for yourself (e.g. Phil, Dave, Joe, etc), the document it came from, and page #. As they get populated I'll look through and can revise the commenting strategy as needed (for example if we want to create a comment document for each document from TFI). Here's the link:

Ex. 5 Deliberative Process (DP)

Make sure to select autosave so that others can be aware of your work while you're adding comments.

Let me know if I can answer any questions.

Subject: RE: Other Uses of Phosphogypsum

Hi Marcos,

Currently, there are no completed and approved applications for other uses of phosphogypsum; therefore, there is no supporting documentation available on our website. In the past there have been several incomplete applications submitted to the Agency. Ultimately, those applications were all withdrawn. I am not aware that the documentation for those withdrawn applications is publicly available. I have copied those who may know more.

Note that The Fertilizer Institute has submitted a request for the Agency to review an other use of phosphogypsum. This request is currently under review and a decision on the request has not been finalized by the Agency.

I hope this is helpful,
Stefanie

Subject: Other Uses of Phosphogypsum

Hi Marcos,

Thanks for taking my call. As mentioned, I am looking for previously-submitted publicly available applications for "other uses" of phosphogypsum. The guidance available on EPA's website (https://www.epa.gov/sites/production/files/2015-05/documents/guidance.pdf) states:

> **How can I find out if there is an earlier application someplace that is similar enough to mine I could use its risk assessment?**
> All applications that may be released to the public will be included in this Web page. You may also contact us at **radiation.questions@epa.gov** if you need additional information.

I have not been able to find the web page referred to in the guidance document. I have not yet emailed radiation.questions@epa.gov, but can do so as a next step if you're also unable to find anything.

Thanks so much for your help.

Warm regards,
Nick

Subject: TFI Communications Plan
Attachments: TFI Communications Plan_8-31.docx

Good afternoon Kati and Enesta,

I wanted to provide an update on our draft (but nearly final) communications plan for The Fertilizer Institute (TFI). As a reminder, this communications plan relates to Agency action on The Fertilizer Institute (TFI)'s application for alternative uses of phosphogypsum. I mentioned earlier in the month that final Agency action is currently pending management and legal review; this is still true, but I anticipate we are more like days away from a final decision timeline, rather than weeks.

Attached is a draft copy of the communications plan that the RPD and ORIA management are currently reviewing. I wanted you to have this advance copy of the communications plan so that you knew what we were working on. I will provide another update once the plan has been finalized internally.

Also, we also heard that TFI does not intend to do a press release for a while, maybe when they get a project it will be appropriate. We thought this would be important for you to know.

Please let me know if you have any questions,
Stefanie

Tony,

Is this attachment on our supporting docs page? I cross walked what Ray has queued up for the docket, and what is on our website, and I couldn't figure out if we missed this one.

Would you mind taking a look. Thanks in advance for double checking,
Stefanie

Hi Stef,

Ahh, my apologies for the miswording/confusion – I have 9 appendices, plus the Attachment A of Road Specs. Not sure why I lumped them all together.

Just for reference, that attachment is tagged onto this e-mail.

Thanks,

Ray

Hi Ray,

I compared the documents Ray listed as being added to the docket and the items Tony has posted to our supporting documents page. It looks like all documents listed on our web page have also been queued up to be on the docket. I only have one question:

Tony & Ray: Is there an additional TFI appendix? Ray mentioned 10 are in the docket. Our website has 9.

Hi all,

All supporting documentation I've received (a total of 15 documents – the PG Risk Assessment Review [plus 10 appendices], the April TFI petition, 1992 BID, memo for road abandonment, and signed letter from the Administrator)

has been processed and uploaded into the docket. Again, the number in regulations.gov is:

EPA-HQ-OAR-2020-0442

As Jon sent out to us, the FR will be published on 10/20. That's plenty of time for the docket staff to do their final QA, so there should not be any issues.

Let me know if I've missed anything or if there are any additional docs we need to have in there in the meantime.

Thanks again all,

Ray

Jon,
I hope the kid situation is under control now.

Lee seemed to be OK with the changes to the document I made so please verify that I did not make any misstatements and incorporate Dan's edits. I know you won't be able to get to it until around noon, but there should not be much to do.

There is a push to get everything loaded onto the web as soon as possible, so can you try to get the final technical review document in a revised Word document and in a pdf document by around 2 pm to us?

Thanks.

Hi Matt,

I am finalizing a communications plan for an impending Agency action related to the approval of an alternative use of phosphogypsum in government road construction projects. We are expecting the Agency to approve The Fertilizer Institute's request to allow incorporation of this material in road beds. This approval should be announced in a matter of days.

In my communications plan, I would like to include a contact for OLEM, just in case anyone in the EPA management chain needs to reach back. Kati Stevens suggested I reach out to you for a contact. Do you happen to have someone I could include?

Thank you,
Stefanie

Hi Jon/all,

We just got this incoming request from Ann Brown over at the Center for Biological Diversity. It's a bit odd, because she's asking for documentation surrounding the FR notice & letter that was signed yesterday...but specifically any records starting on today's date (10/15) through the time we actually conduct the search? I'm not exactly sure what's she's looking for with that date range, aside from the correspondence of us getting all of the supporting materials together.

I know you talked to Jacki Lopez the other day. Do you think they are just looking to get the docketed materials sooner? Actually, the website is up now so all of the documents that will be docketed should be up there as well.

Thoughts? Should one of us give CBD a call/email?

Thanks,

Ray

[ ] The request is reasonably described – clock started – request may need additional clarification
NFO Notes: I wasn't sure if OAR or OCSPP would have responsive records for the attached request. Your guidance is appreciated.

FOIA Program Preliminary Intake Coordination (please complete)

1. [ ] **The request is not reasonably described.** My FOIA Program does not have enough information at this time to identify and locate the records. I understand the NFO will schedule a conference call with the FOIA requester. Our Program would like to be a part of the call: YES [ ] or NO [ ]
   - What additional information is necessary to process this request? (e.g. subject matter, date range, internal or external correspondence):
   - If YES, point of contact from your Program to attend the call:
   - If YES, what are the preferred dates and times to attend the call:

2. [ ] **The request is reasonably described**. My FOIA Program has enough information at this time to identify and locate the records.
   a) [ ] Please assign to my FOIA Program - additional clarification may be handled by my program.
   b) [ ] We would like the NFO's assistance in seeking additional clarification. Please stop the clock and schedule a conference call with the FOIA requester. Our Program would like to be a part of the call: YES [ ] or NO [ ]
      - What additional information is necessary to process this request? (e.g. subject matter, date range, internal or external correspondence):
      - If YES, point of contact from your Program to attend the call:
      - If YES, what are the preferred dates and times to attend the call:

3. [ ] **The request does not relate to work in my program.** Please assign to another FOIA Program or agency.
   - Suggested FOIA Program/agency if known:

4. [ ] OPTIONAL: The request can be responded to, **in part,** with **publicly available** or **previously released records**. The records are available at: *[INSERT LINK HERE].* ***If the publicly available or previously released records fully respond to the request, then the Program Office should prepare the close out letter with information to assist the requestor in retrieving the requested records.***
5.
   - [ ] The enclosed records fully respond to the request; *OR*
   - [ ] The enclosed records partially respond to the request.

If you have any questions about this NFO Intake Coordination, please contact me.

Hi Stefanie,

I think everything in general looks great. There are two minor suggestions I could think of, but neither I think would be necessary.

Jon and Joe,

Could you please put eyes on the web language I am proposing be added to our Subpart R page. Please see below for the additional language, or attached for how the additional language would look within the context of the existing webpage. Yellow highlighting = placeholder text that will need to be updated. Please provide any feedback, I would like to send this to Jessica for review as soon as possible given our timeline on this project.

To: Ruth McBurney <rmcburney@crcpd.org>; Mendy Cremeans <mcremeans@crcpd.org>
Subject: EPA Approval of Request for Other Use of Phosphogypsum

Good morning Ruth and Mendy,

During our last board call, I mentioned an upcoming EPA action related to phosphogypsum. Now that it is official, I wanted to let you know that on October 14, EPA approved a request by The Fertilizer Institute (TFI) for use of phosphogypsum in government road construction projects. This approval is granted under the Clean Air Act and the provisions in 40 CFR 61.206, which allow EPA to approve other uses of phosphogypsum if they can be demonstrated to be at least as protective as keeping the material in a stack, which is the designated management method.

This approval is subject to terms and conditions, and we are not aware of any such projects under consideration at this time. A government agency proposing to use phosphogypsum in this manner would have to submit additional information to EPA and provide an opportunity for the public to review the proposal and documents related to this approval, including the risk assessment submitted by TFI. A key condition is that the road not be abandoned or converted for non-road uses, unless additional risk analyses are conducted and EPA is notified.

Attached are the approval letter and the Federal Register notice, which was published today. You can find more information at https://www.epa.gov/radiation/subpart-r-national-emission-standards-radon-emissions-phosphogypsum-stacks. The official docket for this action can be accessed through www.regulations.gov, search for Docket No. EPA-HQ-OAR-2020-0442.

Please let me know if you have any questions. Thanks.
Stefanie

Good morning Lee and Tom,

We expect to complete our review of the TFI documents by September 11. We can schedule a meeting with you the week of September 14 to discuss our concerns and questions.

Thanks,

Caroline

Andrea,

Attached are the revised transition papers for WIPP and TFI.

Most edits were straight-forward, so I accepted those in Word. I left in those with larger changes, and added responses to comments. I've attached clean copies as well.

Lee and Rick,

Ann C. and Betsy completed their review of the transition papers. Please respond to the questions in the TFI Phosphogypsum paper and confirm that you are comfortable with the remaining edits as soon as possible, and no later than Noon. Ann needs to send these papers on to OGC for review.

Thank you,
Andrea

Jon and Andrea,

Attached are draft materials, two formats, for use tomorrow with Anne. One is a single page (albeit with narrow margins) that lists the conditions by category. The second is a crosswalk table of these same conditions with the regulatory reference and notes. I suspect we would want to use the former with Anne, but we should talk about that.

THE
FERTILIZER
INSTITUTE

December 1, 2020

Ms. Anne Idsal
Principal Deputy Assistant Administrator
U.S. Environmental Protection Agency
Office of Air and Radiation
1200 Pennsylvania Avenue, N.W.
Washington, DC 20460

Dear Ms. Idsal:

On October 14, 2020, The Fertilizer Institute (TFI) received the U.S. Environmental Protection Agency's (EPA or Agency) written approval, subject to certain conditions, of the use of Phosphogypsum (PG) in government road construction projects.[1] A notice of this approval was published in the *Federal Register* on October 20, 2020.[2] TFI appreciates the Agency's decision to approve PG use in road construction as an acceptable alternative to placement in stacks, consistent with Clean Air Act Regulations at 40 C.F.R. § 61.206.

The Agency's approval includes a list of "Initial" and "Other" conditions. EPA's "Initial" conditions refer to the information requirements set forth in the regulations at 40 C.F.R. § 61.206(b) that must be met prior to removing PG from a stack. EPA also determined that roads constructed with PG must be consistent with certain "Other" conditions, including a requirement that "[r]oads constructed with PG may not be abandoned (or otherwise permanently cease to be used as a road) and used for other non-road purposes or uses, including the construction of structures on such former roads."[3]

TFI seeks EPA's clarification of this condition, considering the following information from the administrative record.

1. **The administrative record supports the fact that road abandonment occurs very rarely and is subject to well-defined state and local requirements that are designed to ensure that such abandonment is done in a protective manner and subject to state and local review.**

[1] Letter from EPA Administrator, Andrew R. Wheeler, to Corey Rosenbusch, President and Chief Executive Officer, The Fertilizer Institute (Oct. 14, 2020) (EPA-HQ-OAR-2020-0442-0015) (hereinafter, "EPA Letter to TFI").
[2] 85 Fed. Reg. 66,550 (Oct. 20, 2020).
[3] *See* EPA Letter to TFI at 7.

- EPA's analysis[4] of public road abandonment found that decisions on abandonment are within state jurisdiction and demonstrate that local governments, state entities and the public can and do raise issues in road abandonment proceedings, resulting in limitations on the abandonment.

- Abandonment of government roads is subject to a petition process based on state statutes that include, among other things, public notice and comment and state agency approval.[5]

- Typically, abandonment is limited to a single right-of-way or easement and *structures or improvements are prohibited* in the former road area, except for stormwater, drainage and fencing structures approved by the local government.[6]

2. **In the extraordinary instance that an abandoned road would be repurposed and used for the construction of a house built using modern standards, the risk is 3 in 10,000 or less.**
   - EPA's review of the TFI/Arcadis Risk Assessment[7] acknowledges that "the TFI risk assessment does show that risk to a future resident of the site [*i.e.*, the residents of a house constructed on top of an abandoned road] might be acceptable depending upon the methods used to construct the house."[8]

   - The TFI/Arcadis Risk Assessment considered a road base that was 25 cm thick.[9] For the future resident scenario, TFI/Arcadis selected a 10 cm thick road base, adjusted due to site preparation and removal of the road cover layer (*i.e.*, the future home construction process is expected to result in mixing clean soil with PG).[10] However,

---

[4] *See* U.S. EPA Memorandum from Joseph Rustick, Staff Physical Scientist, Radiation Protection Division, Office of Radiation and Indoor Air, to Tom Peake, Director, Center for Waste Management Regulations (Oct. 15, 2020) (EPA-HQ-OAR-2020-0442-0004).
[5] *Id.* at 1, Att. A, Att. B.
[6] *Id.* at Att. B & C.
[7] U.S. EPA Office of Radiation and Indoor Air, *Review of the Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum Prepared for the Fertilizer Institute* (Oct. 14, 2020) (EPA-HQ-OAR-2020-0442-0018).
[8] *Id.* at 18.
[9] The 25 cm thickness of the road base is consistent with the assumed road base thickness in the TFI/Arcadis Risk Assessment submitted with the Petition. Arcadis Canada Inc., *Radiological Risk Assessment in Support of Petition for Beneficial Use of Phosphogypsum*, at 2-1 (Oct. 2019) (EPA-HQ-OAR-2020-0442-0007) (hereinafter, "TFI/Arcadis Risk Assessment"). This thickness was based on EPA's assumption in the 1992 document entitled "Potential Uses of Phosphogypsum and Associated Risks, Background Information Document" (EPA/520/1-91-029) (April 1992).
[10] The 10 cm thickness is an assumed value as described based on site preparation and road cover removal. This is consistent with the analysis provided in the TFI/Arcadis Risk Assessment submitted with the Petition. TFI/Arcadis Risk Assessment at 3-8.

assuming no further mixing of PG with clean soil, the TFI/Arcadis Risk Assessment shows that the risk would be in the acceptable 3 in 10,000 range using a road base thickness up to 25 cm.[11] Increasing the road base thickness up to 25 cm is not linear with the resulting dose and risk; that thickness would increase the indoor radon concentration by less than a factor of 2,[12] which for 26 years of residence would change the dose of about 46.8 mrem to about 75 mrem, still well below a lifetime reference level of 600 mrem corresponding to a risk of 3 in 10,000.[13] For comparison, the 600 mrem (*i.e.*, 3 in 10,000 risk) requires a Ra-226 concentration of 80 pCi/g (600 divided by 75 times 10 pCi/g). This Ra-226 concentration far exceeds the 35 pCi/g limit in the Petition and the average levels recently measured in U.S. PG stacks.[14]

- The Petition documents that the use of vapor barriers in construction is typical of modern construction practices.[15] However, even assuming no vapor barrier is used in construction, the lifetime dose would increase only to about 470 mrem, still well below the reference dose of 600 mrem corresponding to a risk of 3 in 10,000.[16]
- The existing record also demonstrates that other factors (*e.g.*, cracks in the slab foundation of the newly constructed house) do not significantly increase the risk.[17]

The points set forth above from the administrative record support EPA's conclusions that:

---

[11] The TFI/Arcadis Risk Assessment submitted with the Petition includes Figure 3.2, which shows the increased thickness of the road base would increase the radon flux and ultimately the risk to the reclaimer by less than a factor of 2 and would remain less than 3 in 10,000. *Id.* at 3-10.

[12] The actual modelled increase in indoor radon concentration is about a factor of 1.6, rounded to 2 for illustration. *Id.*

[13] Site preparation would include the addition of aggregate fill between the road base and the concrete slab. This somewhat porous layer would provide some, but not significant, radon mitigation. Consistent with TFI's approach of adopting conservative assumptions, TFI's radon calculation did not take into consideration any mitigation effect of the fill layer.

[14] TFI, *Supplement to The October 11, 2019 TFI Phosphogypsum Reuse Petition: 2019 Radium-226 Results for U.S. Phosphogypsum Stacks* (Dec. 5, 2019) (EPA-HQ-OAR-2020-0442-0011).

[15] As an example, the Florida building code requires vapor barriers to be installed below slab-on-grade floors. Florida Building Commission, Florida Building Code – Residential, Section R506.2.3, 6th Edition (2017).

[16] As described in the TFI/Arcadis Risk Assessment provided with the Petition, the vapor barrier reduces the radon flux by a factor or 10. Removing the vapor barrier affects the calculated result by increasing the radon and dose by a factor of 10. This factor was referenced in the Risk Assessment to: Kitto, M.E., & Perazzo, E., Experimental Determination of the Effectiveness of Radon Barriers (2010).

[17] The use of the diffusion coefficient value in the TFI/Arcadis model is comparable to that found from in-situ investigations and more accurately represents radon diffusion through a concrete slab than laboratory testing on cylinders and is considered reasonable for this purpose. *See* ANL, "Data Collection Handbook to Support Modeling the Impacts of Radioactive Material in Soil" (ANL/EAIS-8) Table 7.1 (1993).

1. Road abandonment and reuse are within the jurisdiction of the states and subject to well-established state and local requirements that are designed to ensure that abandonment is done in a protective manner and overseen by state and local review;
2. Redevelopment and construction on abandoned roads is unlikely; and
3. Any associated risk with a reclaimer scenario is low and can be safely managed through construction practices.

We respectfully request your concurrence with these conclusions. Your response will bring improved clarity and certainty to all stakeholders, including state agencies responsible for implementing the approved use of PG in road construction projects.

Sincerely,

Corey Rosenbusch
President and Chief Executive Officer

Anne,

Attached for your review and signature is an action memo for the Phosphogypsum FRN en route to the Admin. to sign the action and accompanying letter. The review/concurrence email is also attached at the end and just to note that the Comms plan was updated from a desk statement to include a press release. Thanks.

John

Jonathan,

I have reviewed the attached materials. Everything looks great, although I did make changes to the comms plan. My edits are attached.

Please let me know if anything else is needed from the IO to move this along.

Thanks,
Preston

THE FERTILIZER INSTITUTE

June 26, 2020

Honorable Andrew Wheeler
Administrator
U.S. Environmental Protection Agency
1200 Pennsylvania Avenue Northwest
Washington, DC 20460

RE: Petition to Promote Reuse/Recycling of Phosphogypsum

Dear Administrator Wheeler:

We write to request your support for a petition, submitted to the U.S. Environmental Protection Agency (EPA) in the Fall of 2019 by The Fertilizer Institute (TFI), which would facilitate the recycling and reuse of phosphogypsum (PG), a by-product of the production of phosphate fertilizer. TFI represents the fertilizer industry. Our members provide plant nutrients that are responsible for nearly half the world's food supply. Additionally, the fertilizer industry supports nearly 500,000 American jobs and has an economic impact of more than $130 billion annually.

Phosphate is one of three nutrients critical to the growth of crops produced to feed the U.S. population and for export to feed millions around the world. The U.S produces over six million metric tons of phosphate fertilizer annually, making the U.S. the second largest global producer of this product.

Phosphogypsum is used beneficially for various purposes in many countries. However, in the U.S., which produces more than 46 million metric tons of PG annually, these uses are constrained by a 1992 agency rule. Under that rule, with only limited exceptions, phosphate fertilizer producers must place PG in engineered "stacks" adjacent to their fertilizer plants. These stacks are expensive to construct, maintain and close, consume enormous amounts of land that could be put to other productive use, are tall and readily visible, and increasingly have become the subject of public concern. Further, the rule results in significant additional costs on U.S. fertilizer producers, making them less competitive compared to foreign operations. Morocco is the world's leading producer of phosphate fertilizer—by far—and its state-owned company is not subject to comparable PG requirements.

The 1992 rule requires EPA approval for petitions seeking beneficial use of PG. TFI's petition requests that EPA authorize the use of PG as a road-base material or as an ingredient in

Anne, for your awareness, please find attached the 11 transition papers developed by the programs. These papers have undergone review by program leadership, Betsy, OGC, and myself. Also attached is an OAR overview, drafted in the template requested by the OA. The text largely draws upon the web and I suspect can be improved upon as needed.

The programs have been reviewing a number of other submissions from OGC, OITA, the regions and other offices from across the agency. They have done a wonderful job in this first round. All of our papers, along with the ones we've collected with OAR content are housed in a Teams site that we each have access to.

We are on track to meet our deadline to submit these papers to the OA tomorrow.

Thank you,

Ann (Campbell) Ferrio

>
> **EPA approves use of phosphogypsum in roads**
>
> By Bruce Ritchie
>
> 10/14/2020 07:24 PM EDT
>
> U. S. Environmental Protection Agency Administrator Andrew Wheeler on Wednesday approved an industry group's request to allow phosphogypsum, a byproduct of fertilizer production, to be used in building roadways.
>
> Wheeler granted a request from the Fertilizer Institute to use the waste, which contains radioactive material and is being stored in towering stacks at sites around Southwest Florida where fertilizer is produced from phosphate.
>
> Phosphogypsum contains radium, which decays to form radon, a cancer-causing, radioactive gas, the EPA said.
>
> **Details:** Studies from the Fertilizer Institute demonstrated that use of phosphogypsum in road construction is safe, avoids the risk of storing the material and represents the most significant effort towards finding an alternative use for the byproduct since the 1990s, EPA said in a news release. The agency said the group submitted the request a year ago.
>
> "Allowing the reuse of phosphogypsum shows EPA's commitment to working with industry in a way that both reduces environmental waste and protects public health," Wheeler said in the release Wednesday.

Reaction: Some Florida environmentalists were surprised by the announcement and are concerned that allowing phosphogypsum to be used in roads could present health risks from exposure to the material and groundwater contamination.

"Quite frankly this is something we have been preparing for for decades and hoping we would never have to address the issue on the federal level," Glenn Compton, chair of the ManaSota-88, a nonprofit environmental group, said in an interview. "It looks like it has presented itself."

Jaclyn Lopez, Florida director for the Center for Biological Diversity, listed previous studies the EPA had cited previously in determining that phosphogypsum was too radioactive for use in road projects.

"Without seeing the EPA's analysis (assuming there is one), I can't imagine what has changed, except the agency's tolerance for which and how many people get sick or die as a result of exposure," Lopez said in an email.

The prepared Federal Register notice said the agency will publish a docket in the case.

EPA spokesperson Enesta Jones said the agency needed time to respond to criticism and questions about the action announced Wednesday, including how the public could become involved at this point.

Kathy Mathers, vice president of public affairs for The Fertilizer Institute, did not respond to telephone messages and emails requesting comment.

What's next: Compton said he doesn't know what the next step is for ManaSota-88 and other environmental groups until they can review agency documents involving the announcement.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

August 13, 2020

OFFICE OF
AIR AND RADIATION

Mr. Corey Rosenbusch
President and CEO
The Fertilizer Institute
425 Third Street, SW, Suite 950
Washington, D.C. 20024

Dear Mr. Rosenbusch:

Thank you for your letter to the Administrator dated June 26, 2020, regarding the petition submitted to the U.S. Environmental Protection Agency (EPA) by The Fertilizer Institute (TFI) concerning the use of phosphogypsum in road base and road pavement. The Administrator asked that I respond on his behalf.

We appreciate the discussions between EPA and the representatives of TFI and your member organizations on the content of the alternative use request for phosphogypsum. Those discussions have been collaborative and productive, resulting in an updated petition and risk assessment in April. EPA staff are grateful for the active cooperation of TFI's representatives that yielded this updated and improved request. At present, senior managers are continuing the technical and legal analysis necessary to provide a response, which we hope to provide in the near future.

Again, thank you for your letter and for your industry's continued commitment and essential contribution to the nation's food supply. I appreciate the opportunity to be of service and trust the information provided is helpful. If your staff have further questions, please reach out to Lee Ann B. Veal, Director of the Radiation Protection Division at [HYPERLINK "mailto:veal.lee@epa.gov"] or (202) 343-9448.

Sincerely,

Anne L. Austin

Lee,
Do you have access to our phosphogypsum documents in Teams? You don't need to be in the VPN to access the sharepoint files if you use Teams. It is the RadNeshaps Subpart R group, not the TFI Risk Assessment Review group as you may expect. I can't tell who has access.
The technical review document and the road abandonment document appear to be done though there is one edit up for debate on the technical review document.

Hi Tom and Dan,

I'm still trying to square away getting you both on the call with the Administrator officially. Here is the call in and it is at 4:30pm - 5:00 pm on Wednesday. Ex. 6 Personal Privacy (PP) dial-in: Ex. 6 Personal Privacy (PP)

The attached documents were sent today from Ann Campbell Ferrio to the OA. I spoke with Jon this afternoon about the brief. After opening remarks from Anne/Jon, I will plan to start the brief. We've only done one other brief in RPD, but Jon has a little more experience. He recommends going through the briefing materials, augmenting with language from the Action memo and approval perhaps, and keeping it somewhat direct.

Subject: Transition Briefing Papers - due 9/28
Importance: High

Hi Jess, Tom and Ken,

As I mentioned last week, the EPA 2020 Presidential Transition coordination is currently underway. Andrea Cherepy is the lead for ORIA, Ann (Campbell) Ferrio is the lead for OAR, and the Agency level effort will be led by Wes Carpenter, Acting Deputy Chief of Staff in the Administrator's Office.

Under the auspices of the Presidential Transition Act of 1963 and subsequent statutory updates, including the Presidential Transition Enhancement Act of 2019, EPA has major requirements to complete, including the National Program Managers (NPMs) creating and/or updating briefing materials.

Rick and I were able to speak with Jon and Andrea about the RPD submission, and we have these three topics that we feel would be worthy of one pagers for the transition team:

1. WIPP Expansion
2. ORIA ER Responsibilities (includes radiation risk comms, overall preparedness, key exercises in 2021 1Q)
3. Phosphogypsum/TFI

Remember that all information in transition materials must be **publicly available information**. We should use this as an opportunity to showcase our important work and highlight challenges that may be informative to any potential new political leadership.

Here are OAR's briefing paper topics from the 2016 transition:

- Biomass
- Clean Power Plan
- Climate Change & the Transportation Sector
- NAAQS Implementation

- Renewable Fuel Standards
- The Montreal Protocol & HFCs
- The Paris Agreement on Climate Change
- U.S. GHG Emission Trends

As of right now, we are being told to use the 2016 format (see attached examples – Biomass and CPP) for the 2020 transition materials. That could change, however, if OMB, GSA, and OPM requires changes. The Office of the Administrator expects to receive supplemental guidance shortly, so I appreciate your flexibility. While we haven't been given an internal OAR deadline just yet for draft briefing papers, final briefing materials are due to our agency transition team by Friday, October 16. Therefore, we shoot **aim to have our papers complete by September 30th**. As a way of translation for internal RPD review/edit Sept 28. Andrea will let us know if OAR needs them sooner.

I just looked at it and deleted a couple of comments since Dan addressed them.

I think Dan did a terrific job adding in relevant background and focusing the discussion.

I think we can review this in parallel.

ACKNOWLEDGMENTS

I would like to thank my committee chairman, Dr. Timothy G. Townsend for his patience and encouragement throughout my graduate program. I also wish to thank the remaining members of my committee, Dr. Paul A. Chadik and Dr. Ben Koopman for their insight and review of this thesis.

I would also like to thank my fellow graduate students in Solid and Hazardous Waste, for their assistance and support with this study.

Final thanks are extended to Mosaic Fertilizer, LLC, for supporting this research. Special thanks go to Elizabeth Foeller (Research & Development Manager) and Charlotte Brittain (Engineering Superintendent Environmental Solutions). Also I want to thank the Solid Waste Management Division in Polk County, Florida for their help.

TRACE METALS LEACHABILITY CHARACTERIZATION OF PHOSPHOGYPSUM

By

Shabnam Mostary

May 2011

Chair: Timothy G. Townsend
Major: Environmental Engineering Sciences

Phosphogypsum (PG), a primary byproduct from phosphoric acid production, is accumulated in large stockpiles and occupies vast areas of land. The aim of this study was to characterize the trace metals leachability of phosphogypsum under different environmental conditions. For this purpose multiple batch leaching tests were conducted to observe the leaching behavior of PG elements. Based on the toxicity characteristic leaching procedure (TCLP) and extraction procedure toxicity (EPTOX) test, none of the metals (Ag, As, Ba, Cd, Cr, Pb, Se) exceeded the regulatory toxicity limits; thus PG samples tested did not meet the definition of EP Toxicity under the Resource Conservation and Recovery Act (RCRA). It is notable that mercury was not tested in this study. Results from the TCLP, synthetic precipitation leaching procedure (SPLP) and deionized water (DI) extraction, leached relatively similar concentrations of inorganic constituents (except calcium). Aluminum and iron concentrations exceeded their respective groundwater cleanup target level (GWCTL) in SPLP leachates. In the multiple extraction procedure (MEP), most of the metals leached at greater concentration in the second extraction than in the first. In a leaching test utilizing municipal solid waste (MSW) leachate as the extraction fluid, a few constituents of PG

ED_005285_00002627-00015

such as calcium and sulfate considerably leached out. Calcium leached more in the MSW leaching test than TCLP and SPLP. Aside from calcium and strontium there was no significant leaching of other metals in the MSW leaching test. Though concentration of arsenic (UCL_{95}) was above GWCTL in total metal analysis, it was not detected in any of the leaching test.

CHAPTER 1
INTRODUCTION

1.1 Phosphogypsum and Its Management

Phosphogypsum (PG), a waste by-product from the wet manufacturing process of phosphoric acid, is abundant in Florida due to the presence of this industry. The composition of PG is variable and is related to the source of phosphate rock as well as the manufacturing process. Gypsum ($CaSO_4 . 2H_2O$) is the main component; however, PG also contains low concentrations of P and some of the impurities that were originally in the phosphate rock (F, trace elements and naturally occurring radionuclides). Some of the minor elements that are common, such as F, As, Cd, P, and S, have the potential to pose environmental health concern if excessive levels are transported into ground or surface waters. Thus, there are environmental concerns in regards to the potential movement of fluoride, sulfate, certain trace elements, and radionuclides from the phosphogypsum stacks into groundwater. PG is currently placed in large piles or "stacks" to prevent it from entering the environment. Leachate from these "gyp stacks", as they are called, must be properly understood to minimize the risk of environmental contamination.

Prior to 1989, PG was treated as any other item of commerce. The US Environmental Protection Agency (EPA) first issued the National Emissions Standards for Hazardous Air Pollutants (NESHAP) for phosphogypsum in 1989 (54 FR 51654, December 15, 1989). The 1989 rule required that all phosphogypsum be stored in stacks. EPA also prohibited all phosphogypsum research and uses, such as agricultural or indoor research and development.

ED_005285_00002627-00017

In response to several petitions, EPA conducted risk assessments and revised the standard to permit alternate uses of PG in 1992 (40 CFR Part 61, Subpart R). The 1992 revision permitted uses of PG for agricultural uses (as a conditioner for soils containing high quantities of salt or low quantities of calcium and other nutrients), research and development projects and other alternate uses that are approved by EPA on a case-by-case basis.

In 1999 EPA increased the amount of phosphogypsum which may be used in indoor laboratory research from 700 to 7,000 pounds per experiment, with no limit on the number of experiments (40CFR 61.205). Under the 1999 rule, PG may be lawfully removed from a stack and distributed in commerce for use in agriculture if the average radium-226 concentration of the PG does not exceed 10 picocuries per gram (pCi/g)(40CFR 61.204). The owner or operator of the stack from which the PG is removed shall determine annually the average radium-226 concentration at the location in the stack from which the PG will be removed. PG may not be lawfully removed from a stack and distributed or used for any purpose other than agriculture and research purposes without prior EPA approval (40CFR 61.204). This restriction on the maximum radium radioactivity essentially eliminates the use of southern/central Florida phosphogypsum because its radium-226 levels are commonly in the range of 20 to 35 pCi g^{-1} (Guidry 1990; May and Sweeney 1984a). The restriction does not impact phosphogypsum from northern Florida or North Carolina, which generally have lower levels of radium-226.

Considerable research has been conducted to evaluate the leachability of toxic metals (As, Ba, Cd, Cr, Hg, Pb, Se and Ag) from phosphogypsum by TCLP and

ED_005285_00002627-00018

EPTOX. Several researchers have conducted leaching tests to estimate mobility of trace metals, radionuclides and rare earth metals from PG using different leaching solutions like distilled water, aqua regia, salt water etc.

1.2 Objectives

The primary objective of this thesis was to determine typical trace metal leaching behavior of PG using standardized regulatory leaching tests for solid wastes. Leaching tests play an important role in the reuse of raw waste materials as secondary materials. Analyses such TCLP, SPLP, EPTOX, MEP that would typically be required for a beneficial use demonstration in Florida were conducted. These analyses were conducted to evaluate the leachability of trace metals (Ag, Al, As, B, Ba, Ca, Cd, Co, Cr, Cu, Fe, K, Mn, Na, Ni, Pb, Sb, Se, Sn, Sr, V, Zn) in PG. Laboratory leaching tests which generate leachate from waste have been used to evaluate leachability of hazardous constituents (As, Ba, Cd, Cr, Pb, Se, Ag) from PG. The results (total and leachable concentrations of inorganic constituents) were compared to Florida's risk-based target levels like soil cleanup target level (SCTL) and groundwater cleanup target level (GWCTL). PG leachability using different solutions like MSW leachate and DI water was also examined. Knowledge on leaching behavior of PG could help to explore disposal options and assess the risk associated with beneficial-use options for PG.

This study investigates one particular phosphogypsum stack in an attempt to characterize PG leachability that would be typical for many of the other stacks in central Florida. Chapter 2 investigates the literature pertinent to PG production and leachate resulting from PG and leaching tests. Chapter 3 discusses the materials and methodology used in this research. Chapter 4 presents the results from various leaching tests. Finally, discussions of the results are presented in Chapter 5.

ED_005285_00002627-00019

CHAPTER 2
LITERATURE REVIEW

2.1 Phosphoric Acid Production

Phosphogypsum is the primary byproduct generated from the wet-acid process for producing phosphoric acid from phosphate rock. Phosphoric acid is an industrial raw material required for the production of phosphate fertilizer. Phosphate rock, mined in open pit mines, does not have a definite chemical composition and the composition varies in different mining areas. Phosphate ore contains roughly one-third quartz sands, one-third clay minerals, and one third phosphate particles (USEPA 1992). Impurities like calcium, fluoride, chlorides, chromium, rare earths and radio nuclides are also common. United States is the world's leading producer and consumer of phosphate rock and phosphate fertilizers (USGS 2002). Extensive deposits of phosphate rock are found in Florida, Tennessee, North Carolina and Idaho. As a result of the low aqueous solubility of calcium phosphate, the phosphate content of the rock is converted into phosphoric acid to produce fertilizer. Phosphate ore composition partly determines the nature of the phosphorus fertilizer and phosphogypsum. For every ton of phosphoric acid produced, 4.5-5.5 tons of phosphogypsum are produced (Saylak et al. 1988).

According to a mineral industry survey conducted by U.S. Geological Survey (USGS) in 2007, a total of twelve phosphate rock producing mines were active nationwide (Table 2-1). In Florida, phosphate rock is mined and processed by three companies: CF Industries, Inc., The Mosaic Co., and PCS Phosphate Co., Inc. (USGS 2007).

Phosphate rock is usually treated by a physical process called beneficiation; a process prior to acid treatment in order to concentrate the P content of the ore (Becker

ED_005285_00002627-00020

1989). Beneficiation often involves concentration by washing, screening and flotation. Phosphoric acid is produced either by dry thermal or wet acid methods. The dry thermal method produces elemental phosphorus using an electric arc furnace. Phosphoric acid produced by dry thermal process is of a much higher purity and is used in the manufacture of high grade chemicals, pharmaceuticals, detergents, food products, beverages, and other non fertilizer products.

In the wet acid process, phosphate rock is treated with concentrated sulfuric acid and water to produce gypsum ($CaSO_4.2H_2O$), phosphoric acid and hydrogen fluoride. Wet process phosphoric acid is used in fertilizer production because it is more economical. The following is a simplified chemical reaction to illustrate the process (Luther et al. 1992).

$$Ca_{10}(PO_4)_6F_2 + 10H_2SO_4 + 20H_2O \rightarrow 10CaSO_4.2H_20 + 6H_3PO_4 + 2HF$$

Once crystallized, the gypsum is separated from the acid by filtration, mixed with water and transferred as slurry to onsite disposal areas referred to as phosphogypsum stacks. The phosphogypsum stacks are an integral part of the overall wet process.

The phosphogypsum slurry is pumped to the top of the stack and discharged into perimeter deposition ponds. The process water is decanted into a center storage pond and then removed from the stack for recycle via a siphon. The phosphogypsum slurry begins to form a small pond on top of the stack with the growth of stack. Workers dredge gypsum from the pond to build up the dike around it and the pond gradually becomes a reservoir for storing and supplying process water. As the wet process requires large quantities of water, the water impounded on the stack is used as a reservoir that supplies and balances the water needs of the process.

ED_005285_00002627-00021

2.2 Potential Uses of Phosphogypsum

EPA first banned any use of phosphogypsum in 1989. Since then it has been a divisive issue on if and how to use phosphogypsum. As a local material, phosphogypsum stacks can be found extensively in Florida. However, due to the 1992 EPA ban on the use of phosphogypsum, research has slowed dramatically. As a result, special provisions must be made to FDEP and EPA before this material can be used other than agricultural purposes.

It is of interest to the fertilizer industry to find effective and economical long-term solutions for the management of PG; this would help to minimize space requirements and the potential for environmental impact caused by the accumulation of PG stacks.

Several research projects have investigated practical application of PG for a variety of purposes, including its use as road fill material (May 1983; Chang 1989; Lloyd 1985) and as a soil stabilizer (Degirmenci 2006). Several roads and parking lots were constructed using PG or cement-PG. They are used daily in Florida and Texas with no reported negative environmental impacts (Nifong and Harris 1993). Sulfur deficiencies exist in soils of the southeastern US. Phosphogypsum soil amendment is a possible solution to correct this deficiency because it provides a sulfur source that is slowly available to the plants and is not easily leached out of the soil by rainfall (Lloyd 2004).

Stanley and Lloyd (1992) studied phosphogypsum, reporting that PG is currently being wasted and that PG enriches the soil. Lloyd states that “PG has been proven to be a suitable amendment for many soil types and is an excellent fertilizer source of sulfur, calcium and phosphorous”. He argues that “Any soil that tends to surface-harden

ED_005285_00002627-00022

and resist water would benefit from PG. It creates a more porous texture that soaks up rainfall".

In the past, countries such as France and Japan used phosphogypsum for construction of roadways and landfills and as a building material for houses. Research has been conducted in France to use PG for embankment construction (Moussa et al. 1984). Their study showed that re-utilization of PG is possible in well-determined conditions of placement and use.

Studies suggest that PG along with coal fly ash can be used as an amendment to improve rice paddy soil fertility (Lee et al. 2009). It was concluded that the fly ash and PG mixture could be a good source of inorganic soil amendments to restore the soil nutrient balance in rice paddy soil.

Extensive research has been conducted to recover sulfur from PG. In general, sulfate is converted to sulfur dioxide by a high temperature decomposition of calcium sulfate in the PG. The sulfur dioxide is scrubbed from the gaseous emissions and sent to the facility's chemical plant where it is converted to sulfuric acid. This is then utilized in the wet acid process (US EPA 1992). This method is not economical if the price of sulfur is too low.

2.3 Leaching Tests in Solid Waste Management

Leaching is a method to remove soluble components from a solid matrix. Many leaching test procedures have been developed to simulate the leaching processes of wastes in landfills or other disposal scenarios; these assist in evaluating potential risks to human health and environment from solid wastes. Therefore, leaching tests are often used in the decision making process of solid waste management. Leaching tests are used to estimate the potential concentration of contaminant that leaches from a solid

ED_005285_00002627-00023

waste when exposed to water or similar extraction solution. In general, there are two types of leaching tests: batch leaching tests and dynamic column/lysimeter tests. Some common batch leaching tests include Extraction Procedure Toxicity (EPTOX), Toxicity Characteristic Leaching Procedure (TCLP), Synthetic Precipitation Leaching Procedure (SPLP), American Society for Testing and Materials (ASTM) extraction test and Multiple Extraction Procedure (MEP). While batch leaching tests are characterized by a constant liquid to solid ratio, dynamic leaching tests are characterized by increasing liquid to solid ratio as the experiment proceeds. Batch tests typically involve adding waste to an extraction solution and then agitating the mixture for a short period of time (typically less than 24 hour).Thus, batch tests offer a relatively rapid, cost effective method for the assessment of metal leachability. Batch tests are primarily conducted as a regulatory tool but they can also be conducted in a manner to examine a specific variable's influence on metal mobility, like impact of pH, liquid to solid ratio, etc.

2.3.1 Toxicity Characteristic Leaching Procedure (TCLP)

TCLP (EPA Method 1311) is the most frequently used batch test in the management of solid waste. The TCLP was designed by the US Environmental Protection Agency (EPA) to provide a relatively quick test to determine whether a solid waste should be characterized as hazardous and thus be managed in a more controlled manner. The TCLP attempts to mimic reducing, low pH environmental conditions in MSW landfills. The extraction fluid (pH 4.93 ± 0.05) simulates a scenario where a potentially hazardous waste is co-disposed with MSW. The primary extraction fluid is a buffered acetic acid solution in a liquid to solid ratio of 20:1 for 18 ± 2 hours. Particle size reduction is required if the particle is greater than 1 cm in its narrowest dimension. The concentrations of contaminants are compared to toxicity characteristic (TC) limit

ED_005285_00002627-00024

concentrations outlined in 40CFR261.3 to determine hazardous waste designation. The TC limits for the eight metals used in determination of hazardous waste are presented in Table 2-2. Note that there are a number of organic contaminants which also carry a toxicity characteristic limit. TCLP uses acetic acid (weak acid) which has a strong ability to complex or chelate metals.

2.3.2 Synthetic Precipitation Leaching Procedure (SPLP)

The SPLP is an EPA SW-846 analytical method (EPA Method-1312) designed to mimic the mobility of toxic contaminants when exposed to acidic rainfall. The SPLP is thus used to evaluate the potential for metal leaching into ground and surface waters from waste exposed to rainfall (Jang and Townsend 2001; Brantley and Townsend 1999). The time and liquid-to-solid ratio are the same as in the TCLP, but SPLP utilizes an extraction fluid intended to simulate precipitation or acid rain. Particle size reduction is required if the particle is greater than 1 cm in its narrowest dimension The extraction fluid (pH 4.2 ± 0.05) is made of two inorganic acids (nitric and sulfuric acid) to simulate acidic rainwater.

2.3.3 The US EPA Multiple Extraction Procedure (MEP)

The MEP simulates leaching caused by the repetitive precipitation of acid rain water (EPA Method 1320). MEP may be used to address long-term leachability. MEP is designed to simulate the leaching that a waste will undergo from repetitive precipitation of acid rain on an improperly designed sanitary landfill. The repetitive extractions will give the highest concentration of each constituent that is likely to leach in a natural environment. This test utilizes an initial acetic acid extraction (pH 5 ± 0.2) followed by sequential extractions with simulated acid rain So, MEP combines aspects from both the TCLP and the SPLP. Extraction on the first day calls for TCLP extraction fluid at a

liquid-to-solid ratio of 20:1; thereafter, the procedure calls for SPLP extraction solution (pH 3 ± 0.2) (at least eight subsequent extractions) at the same liquid-to-solid ratio. Details are discussed in Chapter 3.

2.4 Leaching Tests for Assessing the Potential for Groundwater Contamination

Leaching of pollutants to groundwater is a very complex process influenced by several factors such as meteorological parameters (e.g., rainfall), soil properties (particle size distribution, organic carbon content), and physical-chemical characteristics (Kördel and Klein 2006).

Regulation of groundwater quality is generally under state jurisdiction; most states have their own risk-based regulatory thresholds regarding contaminant transport from soil to groundwater. The state of Florida has what are known as Soil and Groundwater Cleanup target Levels (SCTL and GWCTL). The SCTLs consist of over 350 individual chemicals with pre-calculated total constituent concentration thresholds based on-direct human contact with soil and potential for soil contamination to migrate to groundwater. Different limits reflect different possible groundwater uses. The worst case scenario is where the water is assumed to be used for direct human consumption.

The GWCTLs are a similar list of maximum leachable concentrations for various constituents. For particularly hazardous constituents, the US EPA primary and secondary drinking water standards (Table 2-3) are generally used for the GWCTL. SCTL were developed based on direct human contact (i.e., direct exposure), and based on soil acting as a source of groundwater or surface water contamination (i.e., leachability). The US EPA has developed measurements of cancer potency of carcinogens, which are termed cancer slope factors (CSFs). Risk-based soil cleanup guidelines have been developed for both carcinogens and non carcinogens. For non-

ED_005285_00002627-00026

cancer risks, the reference dose (RfD) is the term used to refer to the maximum acceptable exposure. RfD's are determined from Lowest Observed Adverse Effect Level (LOAEL) or No Observed Adverse Effect Level (NOAEL) measurements that have been multiplied by a series of uncertainty factors. There are separate RfDs for different pathways of exposure (Oral, inhalation). For calculating SCTL, we need to consider different pathways (ingestion, inhalation, dermal exposure). As for example, equation for a cancer risk from soil exposure through ingestion will be, CTL (mg/Kg) = {Target Cancer risk X Body weight (Kg)}/ {Oral Cancer Slope Factor $(mg/kg\text{-}day)^{-1}$X ingestion rate (mg/day)}.

The formula for calculating GWCTL (carcinogen) is, GWCTL (mg/L) = {Target Cancer risk X Body weight (Kg)}/ {Oral cancer slope factor $((mg/kg\text{-}day)^{-1}$ X Average Water Consumption Rate (L/day)}.

Body weight and water consumption are assumed for calculation. For non carcinogen it will be only, GWCTL= {(RFDX Body Weight)/Water consumption rate}. Since metals present in land-applied solid waste may leach from the waste and migrate to the groundwater (Townsend et al. 2003), possible risk to ground water should be assessed. In Florida and many other states, leaching risk is evaluated by conducting the SPLP and comparing the results to the aforementioned risk-based groundwater standards. This approach is typically viewed as being more representative because the chemical nature of the waste, which can impact leaching, is tested.

2.5 Characteristics of Phosphogypsum

The chemical and mineralogical characteristics of phosphogypsum vary depending upon the nature of the phosphate ore, the type of process used in fertilizer manufacturing, the efficiency of plant operation, the age and location of the stockpile,

ED_005285_00002627-00027

and any contaminants which may be introduced into the phosphogypsum at the production plant (Arman and Seals 1990). Calcium and sulfate dominate the composition of phosphogypsum because it is approximately >90% gypsum (Berish 1990). PG normally has a pH between 4.5 and 5.0. Acidity of PG is due to residual phosphoric acid, sulfuric acid and fluoride acids contained within the pore spaces. May and Sweeney (1984a) found the pH of extracts from Florida phosphogypsum to range between 2.1 and 5.5. Metal concentrations in PG have been thoroughly characterized and typical concentrations are summarized in Table 2-4. These elemental compositions may vary greatly depending on the source of the phosphate rock.

2.6 Phosphogypsum Leaching Studies

The leaching behavior of materials depends on several parameters. These include specific element solubility and availability or release potential. Again solubility can be influenced by pH, complexation by inorganic species or dissolved organic matter, and reducing properties (Kim 2002).

May and Sweeney (1984a) investigated nine PG stacks in Florida to study various physical and chemical characteristics of PG. Results for this analysis showed that the trace elements were uniformly distributed within the PG stacks. May and Sweeney (1984b) evaluated the leachability of Ra and elements the EPA has classified as toxic (As, Ba, Cd, Cr, Pb, Hg, Se, and Ag) by using the standard EPA 'EP' extraction procedure (Federal Register 1980). The concentrations of toxic elements in the extract were all below EPA maximal concentrations, therefore the material was considered non-toxic by EPA standards. The authors estimated that the inclusion of Ra into the phosphogypsum crystal structure would be 89% of the amount originally present, indicating that very little Ra would be leached. They concluded that phosphogypsum

could not be classified as a hazardous waste because it was neither corrosive nor caustic (pH was > 2 and < 12.5). In addition the average total elemental concentrations of elements classified as toxic by the EPA were less than the EPA allowable toxic elemental criteria for toxic hazardous waste (Federal Register 1980).

Rusch and Seals (2004) conducted TCLP on raw PG and oven dried PG samples (oven-dried at 45°C for 12 hours and ground to pass through a US Standard sieve No.10.) collected from Louisiana. The metal concentrations in the leachate from both type, were also well below the US EPA toxicity characteristics limits. Also, there was no significant difference between these two types of samples.

Kendron (1996) conducted EPTOX and TCLP on raw PG specimens to understand the leaching behavior of As, Ba, Cd, Cr, Pb, Ag, Hg and Se through phosphogypsum. The results indicated a potential leaching of these species. Although, the leachate concentration levels were below the US EPA toxicity limits, the concentrations failed to meet the US EPA drinking water limits for several species.

To determine the potential environmental impact of phosphogypsum, Naff (1984) conducted EPTOX on phosphogypsum. The results were within the permissible EPA limits for toxicity; however SO_4^{2-} and fluoride levels exceeded drinking water standards. Haridasan (2002), conducted leaching studies on PG samples (Kochi, India) using distilled water (pH 6.0) and rainwater (pH= 5.0–5.8) as leachants. They varied contact time and solid/liquid ratio in the leaching procedures. The laboratory results indicated that rainwater leached less ^{226}Ra than distilled water.

The leachability of Cd, Cu, U and Zn in Syrian PG was studied by Al-Masri et al. (2004). They did leaching test of PG with distilled water and concluded that Cu and Cd

ED_005285_00002627-00029

are easily transferrable to water or surrounding environment. They also grouped PG into six different particle sizes to observe the effect of particle size on leachability and found that fine particles (45–75 mm) yielded a relatively high solubility.

CHAPTER 3
METHODS AND MATERIALS

3.1 Overview

To assess the leachability of various trace metals from phosphogypsum (PG), samples were extensively analyzed with respect to composition and leaching behavior. Inorganic element concentration from acid digestion and leaching samples were analyzed using Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES).This section will describe the preparation of the samples and methods that were followed to carry out the leaching tests.

3.2 Sample Collection and Processing

PG was sampled from the top of a PG stack located in Mulberry, Florida. Samples were collected from four locations: the north, south, east, and west walls of the top stack. Samples were retrieved from depths of 1 to 2 feet from the top of the stack. PG samples were named north wall (NW), south wall (SW), east wall (EW) and west wall (WW) based on their locations. PG samples were collected by using cleaned scoops, trowels, shovels, and were placed in five-gallon buckets (HDPE) then sealed with lids. PG samples were then transported to the UF laboratory. A total of 330 kg of PG was collected from each of the four sampling locations. In the lab, samples collected from different locations were not mixed together. But samples collected from different depths for each location were thoroughly mixed to get a homogenous sample for that location Samples were stored in closed containers in the lab at room temperature. To perform research on PG, the requirements of 40 CFR 61.205 were followed; all PG was accompanied by certification documents that conformed to the requirements of 40 CFR 61.208. The total quantity of PG at a facility did not exceed 7000 lbs. Containers of PG

ED_005285_00002627-00033

were labeled with the following warning: “Caution: Phosphogypsum Contains Elevated Levels of Naturally Occurring Radioactivity”.

3.3 Leaching Procedures

Four regulatory-based leaching tests were performed-TCLP, SPLP, EPTOX, and MEP. The TCLP, SPLP, EPTOX, and MEP were developed by the US Environmental Protection Agency (EPA). In addition, several experiments were conducted in a similar fashion as TCLP but substituting actual landfill leachates and DI water as the leaching solution.

3.3.1 Toxicity Characteristic Leaching Procedure

The TCLP method is defined in EPA Method 1311.TCLP uses one of two different extraction fluids, depending on the alkalinity of the waste. Extraction fluid 1 is prepared by diluting a mixture of 11.4 mL acetic acid (CH_3COOH) and 128.6 mL of 1N sodium hydroxide (NaOH) to 2L deionized water (DI). The resulting solution pH is 4.93 ± 0.05. Extraction fluid 2 is used for highly alkaline materials. This solution is prepared by adding 11.4 mL acetic acid to 2L deionized water. pH of this solution should be 2.8±0.05. Because the pH of the PG sample was less than 5, extraction fluid 1 was used. The TCLP requires that samples first be size-reduced to less than 0.95 cm in any dimension. One hundred grams of the size-reduced samples were placed in a 2.2-L TCLP extraction vessel, and 2.00 L of the extraction solution were added. The slurry was mixed on a rotary extractor for 18 ± 2 hr at 30 ± 2 revolutions per minute and then filtered through a 0.7 μm glass fiber filter. The filtrate was collected in 500 mL plastic bottles (HDPE) and preserved by adjusting the pH to less than 2 using nitric acid. The leachates generated by the TCLP process were acid digested and analyzed using ICP-AES.

ED_005285_00002627-00034

3.3.2 Synthetic Precipitation Leaching Procedure

SPLP leachates were prepared according to the procedure outlined in EPA method 1312. A concentrated SPLP solution was prepared by adding 100 mL of one percent (by volume) solution of concentrated nitric acid and 100 mL of one percent solution of concentrated sulfuric acid, and then combining these in a 2 parts nitric to 3 parts sulfuric ratio (40%:60%). Then, 0.4 - 0.5 mL of concentrated SPLP solution was added to reagent water in a 2-L volumetric flask and diluted to 2-L. The resulting SPLP solution pH was required to be 4.20 ± 0.05. The SPLP requires that samples first be size-reduced to less than 0.95 cm. One hundred grams of the size-reduced samples were placed in a 2.2-L SPLP extraction vessel, and 2 L of the SPLP solution were added. The slurry was mixed on a rotary extractor for 18 ± 2 h. After the extraction procedures, separation of the leachate solution from PG was completed using a vacuum filtration set-up. The filter used was a 0.7 μm acid-washed glass fiber filter .The rotary extractor was used during the TCLP and SPLP tests was designed to rotate eight 2-L bottles in an end-over-end fashion. When loaded with a full load, each extractor rotates at 30 rpm as required by the TCLP and SPLP procedures. The filtrate was collected in 500-mL plastic bottles and preserved by adjusting the pH to less than 2 using nitric acid.

3.3.3 Extraction Procedure (EP) Toxicity Test Method

The method is defined in EPA Method 1310b.This test requires the continual addition of acid to maintain a constant extraction pH. For the EPTOX, 100 g of sample were placed in 1.6 L of deionized water and agitated for 24 hours. The method requires that the pH of the mixture be maintained at 5 ± 0.2 by adding 0.5N acetic acid. The PG samples in this study did not require any further acid addition. After 24 h of extraction,

ED_005285_00002627-00035

deionized water was added to bring the total volume of the extraction fluid to 2 L. The leachate was filtered using 0.45-μm filter.

3.3.4 Multiple Extraction Procedure

This test utilizes an initial acetic acid extraction followed by sequential extractions with simulated acid rain. The initial extraction fluid is the same as the EPTOX. The simulated rainfall extraction solution is similar to the SPLP leaching fluid but with a pH of 3.0 ± 0.2. This synthetic acid rain extraction fluid was prepared by adding 60% sulfuric acid and 40% nitric acid (weight percent) to distilled deionized water until the pH is 3.0 ± 0.2. The residual solids after the extraction were re extracted nine times consecutively using synthetic acid rain extraction fluid. An initial sample size of 12.5 g was used. Each extraction step is performed at an L/S ratio of 20:1 for 24 h. After each filtration, both the filter and the sample were added to the next extraction vessel. The final pH values of leachates and metal ion concentrations were determined for each extraction.

3.3.5 Batch Leaching Test with MSW Leachate

This batch leaching test mimicked the condition that MSW landfill leachate directly contacts PG and measured any constituent change before and after mixing MSW leachate with PG. This test method is similar to the TCLP or SPLP test except that it uses MSW landfill leachate as the extract solution. A 100 g sample of PG was mixed with 2 L of MSW leachate and mixed for 18 ± 2 hours using a rotating shaker at 30 rpm. The mixture of MSW landfill leachate and PG was filtered using 0.7 μm glass fiber filter after the rotation. Inorganics were analyzed after acid digestion. For this test, MSW landfill leachate was obtained from Polk County North Central landfill. The pH of leachate was 7.6 and totals dissolved solids (TDS) was 6300 mg/L.

ED_005285_00002627-00036

3.3.5.1 Sulfate analysis

Sulfate concentration in leachate samples from batch leaching test of PG (with MSW leachate) was determined using a spectrophotometer (DR/4000 UV-VIS, HACH, Loveland, CO) with HACH Method 8051. A sample cell was filled with 25 mL of sample. One SulfaVer® 4 reagent powder was added to the cell. Sulfate ions in the sample react with barium in the SulfaVer® 4 and form a precipitate of barium sulfate. The amount of turbidity formed is proportional to the sulfate concentration.

3.3.5.2 Total dissolved solids (TDS)

Total dissolved solids (TDS) of the leaching solution from the batch leaching test with MSW leachate was determined following EPA method 160.1. For this, aluminum weighing dishes were placed in an 180°C drying oven one day before the test. Desiccators were used to cool the dishes. Pre-dried dishes were weighed. A total of 100 mL sample was filtered using vacuum filtration. Filtrates were placed into an oven at 95°C for 18 hours to allow the samples to evaporate to dryness. After 18 hours, temperature was increased to 180°C and continued at least for another 4 hours. The dishes are removed from the oven and placed in the desiccators to cool for 30 minutes. Then the dishes were returned to the 180°C oven for 1-2 hours and weighed. This drying and weighing cycle was repeated until the last two weighings differ by less than 0.5 mg. Dishes were then placed in the desiccators to cool for at least one hour. Then the dish containing the oven-dried sample was weighed to the nearest 0.1 mg. TDS was determined using Equation 3-1.

$$TDS\left(\frac{mg}{L}\right) = \frac{\{[\text{final wt.of dried residue + dish (g)}] - [\text{wt.of dish (g)}]\} \text{ x } 1000000}{\text{Volume of sample (ml)}} \quad (3\text{-}1)$$

3.3.6 Batch Leaching Test with DI Water

This test is similar to TCLP/SPLP except DI water was used as the leaching solution. For this batch test 100 grams of PG was mixed with 2 L of DI water in a 2.2 L glass jar. The mixture was agitated using a rotator for 16 to 20 hrs. After tumbling, the slurry was filtered to separate PG leachate from the slurry. Then samples of this PG leachate was retained for the chemical analysis.

3.4 Total Metal Analysis

Samples were digested to prepare them for trace metal analysis. The leaching test samples from various batch tests were digested according to US EPA Method 3010. To determine total metal concentration of PG, samples were digested according to the US EPA 3050B. Digestion procedure was used to prepare aqueous leachate samples that may contain insoluble colloidal particles for analysis by Inductively Coupled Plasma Atomic Emission Spectrophotometer (ICP-AES). Leached and digested samples were analyzed using ICP-AES as per US EPA SW846 method 6010B.

For digestion of aqueous samples nitric acid is added to a specified volume (50 mL) to the sample. The sample is refluxed with additional portion of nitric acid until the digestate is clear or the color is stable. When the digestate reduced to a low volume, it is then finally refluxed with hydrochloric acid and brought up to volume. The digested sample is than analyzed by ICP-AES.

For digestion of solid PG, 1 gram (dry weight) sample was digested with repeated additions of nitric acid (HNO_3) and hydrogen peroxide (H_2O_2). For ICP-AES analyses, hydrochloric acid (HCl) is added to the final digestate and the sample is refluxed.

ED_005285_00002627-00038

3.5 pH of Phosphogypsum

The pH values of PG samples were determined by EPA method 9045D. For this, 20 grams of PG was mixed with 20 mL of reagent water and stirred continuously for 5 min. Then it was allowed to stand for 1 hour. After that, pH was measured.

3.6 Quality Assurance and Quality Control

All sampling equipment and containers were cleaned and prepared according to the US EPA established standards. In the laboratory, analysis blanks, duplicates and calibration check samples were analyzed as appropriate. For total metal analysis every digestion event included (approximately 20 samples) a blank sample, a duplicate sample, a triplicate sample, a matrix spike, a matrix spike duplicate for digestion. All regulatory batch leaching test were conducted in triplicate. However for digestion, a blank, duplicate sample, a sample spike and a sample spike duplicate were included.

ED_005285_00002627-00039

CHAPTER 4
RESULTS

4.1 Total Metal Analysis Results

The chemical composition, which was determined using the US EPA Method 3051b, of the PG samples from each location is shown in Table 4-1. Samples were analyzed for 23 metals (silver, aluminum, arsenic, boron, barium, beryllium, calcium, cadmium, cobalt, chromium, copper, iron, potassium, magnesium, manganese sodium, nickel, lead, antimony, selenium, tin, vanadium and zinc.). Calcium was the most abundant metal detected in PG and ranges from 113,220 (± 58,100) to 171,200 (± 25,900) mg/kg. The minor constituents of raw PG were Al, Fe and K which each had a concentration that exceeded 100.0 mg/kg. Trace elements, such as As, B, Ba, Cr, Cu, Mn, Pb , Sn, V and Zn were also present. Ag, Cd, Co, Mg, Mo, Na, Ni, Sb and Se were not detectable in the samples that were tested. For PG metal analysis, triplicate samples from each location were analyzed. Of the RCRA TC limit metals, barium had the highest concentration (38.6 mg/Kg). Concentrations of other toxic metals (As, Cr, Pb) were below 3 mg/Kg. To use PG beneficially, to where direct human contact with the PG is possible, comparison with risk based standards is needed. Although risk assessment through direct exposure is not the focus of this research, it is discussed briefly as it would certainly need to be considered as part of any beneficial use application. Table 4-3 compares the concentration for each metal with its respective Florida's risk based soil cleanup target level. Florida's SCTLs examine direct exposure in two scenarios, residential and industrial settings. Of the metals detected in PG, the 95% Upper Confidence Limit (UCL_{95}) of only one metal (arsenic) was slightly above its SCTL for residential exposure but below the industrial limit. UCL_{95} was calculated using

ED_005285_00002627-00040

samples from all four locations. In Table 4-1, the average concentrations with standard deviations for each PG sample are presented. Detailed total analysis results are given in Appendix B.

4.2 pH of Phosphogypsum

The pH of PG samples used in this study was in the range of 4.5-4.8 (Table 4-2). One PG sample from each location was tested for pH. The pH of DI water used for this experiment was 6.3. Though PG is composed primarily of the slightly soluble neutral salt, calcium sulfate dihydrate, the acidity may be due to residual phosphoric and sulfuric acids plus hydrofluoric and fluosilicic acids (Smith and Wrench 1984).

4.3 Toxicity Characteristic Leaching Procedure (TCLP)

US EPA specifies toxicity characteristic limits based on the metal concentrations in the TCLP leachates. If any listed compound (mentioned in Chapter 2) exceeds the level specified, the original waste is considered hazardous. The TCLP leachates for raw PG were analyzed for trace metals that are on EPA's list of toxicity characteristic elements such as silver, arsenic, barium, cadmium, chromium, lead and selenium. Mercury was not tested in this study. The TCLP was performed on 12 samples (triplicate samples for each of the 4 locations). All the metal concentrations in the TCLP leachate analyzed for each location were well below the respective regulatory levels. TCLP test data are presented in Figures 4-1 through 4-4. Samples whose concentrations are below detection limits are presented in the plots on the MDL (method detection limit) line. In general, barium leached at higher concentrations than chromium. The mean barium concentration of all 12 samples was 0.11 mg/L (0.07–0.16 mg/L).

ED_005285_00002627-00041

4.4 Synthetic Precipitation Leaching Procedure (SPLP)

The average concentrations (from the four samples; each sample was measured in triplicate) of 21 inorganic elements in the extraction fluids from SPLP test were determined. Eleven of them were detected at concentrations above their respective detection limit. As, B, Be, Cd, Co, Pb, Sb, Sn, Sr, V were not detected in SPLP.SPLP results were compared with Groundwater Cleanup Target Levels (GWCTL). Most of the metals were well below GWCTL except for aluminum and iron. Aluminum concentration is greater than the GWCTL for all the samples. Iron concentration is greater than GWCTL for six samples out of twelve. Even though aluminum and iron are the secondary standards, these results may be questioned by a regulatory agency when PG is considered for use in land application. SPLP results are presented in Figures 4-5 through 4-13 and detailed data are given in Appendix C.

Figures 4-14 and 4-15 show the initial and final pH's for the TCLP test and SPLP test, respectively. The final pH in the SPLP test was consistently lower than the TCLP test in terms of final pH. Figure 4-15, which shows the initial and final pH's in the SPLP tests, shows that the final pH's are generally consistent regardless of the location of the sample.

4.5 Extraction Procedure Toxicity

EPTOX was conducted on PG samples of one location (SW) in triplicate and of the 22 metals analyzed aluminum, barium, calcium, chromium, copper, iron, potassium, magnesium, nickel, strontium and zinc were detected. Final pHs of extraction fluids were greater than SPLP but close to TCLP test (Table 4-4). The TCLP extracted slightly higher concentrations of all the metals than EPTOX except copper, nickel and zinc. Both tests use acetic acid as leaching solution but they have different pH. EPTOX

ED_005285_00002627-00042

results are presented in Figures 4-16 through 4-20 and detailed data are given in Appendix E.

4.6 USEPA Multiple Extraction Procedure

The MEP is used to assess long-term leachability of waste by combining aspects from both the TCLP and the SPLP. The method requires sequential extraction of the same waste. With each subsequent extraction, it is usually expected that leaching concentrations will be decreased with time as there are less contaminants available for leaching. As samples from all the locations showed similar leaching concentrations, the MEP was conducted on samples from only one location (SW) in triplicate. Of the 21 metals analyzed only aluminum, barium, beryllium calcium, chromium, copper, potassium, magnesium, nickel, strontium and zinc were detected above their respective detection limit. The barium, copper, magnesium and potassium results are typical of most sequential leaching tests, with the concentrations decreasing with consecutive extractions. However, for other detected metals, an increase in concentration is observed in the second extraction compared to the first extraction. This may be due to the change in pH (Table 4-5). After the initial increase the metal concentration stabilized and began to decrease with subsequent extractions. Results are presented in Figures 4-21 through 4-26.

4.7 Additional Leaching Testing

4.7.1 The Deionized Water Batch Leaching Test

Batch leaching test with DI water was conducted on samples of all four locations in duplicate (Figures 4-27 through 4-31, Table 4-6). Calcium, which was predominant, leached more in DI leachate than SPLP. Average calcium concentration in SPLP leachate is 656 mg/L and 808 mg/L in DI water leachate. Of the 22 metals analyzed

ED_005285_00002627-00043

only aluminum, barium, calcium, copper, potassium, molybdenum, sodium, nickel, strontium and zinc were detected above their respective detection limit. Iron, which was detected both in SPLP and TCLP test, was below its detection limit when leached with DI water. Barium concentration was also higher in both TCLP and SPLP than DI water leaching test. Again, copper concentrations leached by DI water were higher than both SPLP and TCLP. Other than these metals, when PG samples were leached with DI water; extracted concentrations were somewhat similar to the SPLP.

4.7.2 Batch Leaching Test with MSW Leachate

Figures 4-32 through 4-40 present the results of the leaching tests where MSW leachates were used as the extraction fluids. Table 4-7 presents the result of the final pH of MSW leaching solutions. This leaching test was carried out on samples of all four locations in triplicate. Samples were analyzed for 22 metals. Only antimony, copper, selenium and tin were below their respective detection limit. Concentrations of most cations in the MSW leaching solution were similar to those in the MSW leachate except calcium, iron and strontium. While iron concentration decreased after contacting with leachate, strontium concentration increased. Calcium concentrations in MSW leaching solution were up to one order of magnitude greater than those in the MSW leachate. Concentrations of sulfate and TDS in the MSW leachate were compared to those in the original MSW leaching solutions (Figure 4-41 and 4-42). Sulfate concentrations in the leachate ranged from 3,000-3,250 mg/L. These sulfate concentrations are 15 times greater than those in original MSW leachate. TDS measured in the leaching solutions ranged from 9,350-9,500 mg/L. TDS concentration in the original MSW leachate was about 6,300 mg/L.

CHAPTER 5
DISCUSSION

5.1 Comparison to Previous Studies

TCLP results found in the previous studies are presented in Table 5-1. In the present study only barium and chromium were detected above detection limits in TCLP, and both were below their respective TC limits. Concentrations of these toxic metals were found below their TC limits in previous studies as well. Mercury was not analyzed in this study; Kendron (1996) reported mercury concentration in TCLP leaching solution from PG below its toxicity limit.

Al Masri et al. (2004) conducted leaching of PG (Syrian) using DI water as a first step of sequential leaching test. In their study they used 1 g PG and 100ml DI water for leaching (L/S ratio of 100:1). The results of the current DI water leaching test are compared with the results obtained in the 2004 study for Cd, Zn and U in Table 5-2.Though Cd was not detected in this study, Zn was leached at a much higher concentration than the previous study. This may be due to the high L/S ratio (20:1) used for this study. The bioavailability and mobility of trace metals (As, Cd, Cr, Cu, U, Zn) were estimated by Al-Hwaiti et al. (2010) using aqua regia leaching solution. Results are presented in Table 5-3.They used 50 mg of dried PG and 5 ml of nitric acid and hydrochloric acid (aqua regia) and rotated for 48 hours. All the metals tested leached below 10% (fraction leached) but the concentrations of all the metals were above detection limits. In comparison to that study, SPLP performed in this study leached a higher percentage of Cr, Cu and Zn.

Metal concentrations of PG is compared with gypsum wallboard in Table 5-4 Relative to gypsum wallboard, PG was elevated in total content of Al, As, Ba and K.

ED_005285_00002627-00088

5.2 Discussion of Leaching Results

Arsenic was detected above SCTL in total metal analysis. But it was not detected in any of the leaching tests. When metal concentrations extracted by the SPLP are compared to those of the TCLP, calcium was leached to a greater extent in the TCLP than in the SPLP; silver, arsenic, boron, cadmium, cobalt, magnesium, lead, antimony, tin and vanadium were not detected in either test. Barium, chromium, iron and strontium concentrations in the TCLP leachate were higher than the SPLP leachate, but relatively similar. Only sodium was dramatically greater in the TCLP compared to the SPLP, but this was because sodium is used in the TCLP solution. The TCLP and SPLP extracted statistically similar concentrations of aluminum, copper, potassium, nickel and zinc. Comparisons of TCLP and SPLP for other wastes have found that TCLP typically extracts more metals than SPLP because of the buffered pH of the TCLP and the ability of acetic acid to complex heavy metals. The degree of complexation differs depending on the metal. Differences in metal leachability between TCLP and SPLP could be result from several other factors. The initial pH of the SPLP solution (4.2) is less than the initial pH of the TCLP solution (4.9). Also changes in the solution pH that occur during the 18 hour of leaching may differ between SPLP and TCLP, and thus result in different amounts of metal leaching. In the case of PG, the pH difference between the two tests was not very pronounced. The difference in metal concentrations between SPLP and TCLP for PG are relatively small.

Figures 5-1 through 5-4 compare the average leachate concentrations using SPLP, TCLP, DI and EPTOX for aluminum, barium, chromium and calcium. For aluminum, all the tests leached similar concentrations and all of them were above GWCTL. Barium was below TC limit for all the tests and TCLP leached barium greater

ED_005285_00002627-00089

than SPLP and EPTOX. While MSW leaching solution leached calcium more than TCLP, EPTOX and DI showed similar concentrations of calcium.

When the PG samples were leached with DI water, extracted concentrations were relatively similar to the SPLP except calcium. DI water leached more calcium than SPLP. The pH of DI water used for this test was greater than the TCLP and SPLP extraction solutions. The pH is known as a major controlling factor for metal leachability (Van der Sloot et al. 2001; Townsend, et al. 2004). The solubility of some metals increased under extreme pH but this may not be applicable for all. For some metals the change in pH had no effect (Tolaymat et al. 2008; Chuan et al. 1996). For some wastes like wood, tire ash and wood ash, calcium, potassium and sodium concentrations were controlled by solubility rather than pH (Tolaymat et al. 2008).This may be the case for PG also.

The fact that most of the metals (except calcium) leached less in the MSW landfill leachate relative to TCLP and SPLP is likely a result of the higher pH. Average pH of leaching solution after 18 hours of agitation was 7.5 and initial pH of MSW leachate was 7.7 (Table 4-7). MSW leachate also leached considerable amount of sulfate from PG. Under anaerobic landfill conditions, sulfate-reducing bacteria produce hydrogen sulfide (H_2S) from the sulfate (SO_4^{-2}) in gypsum and the organic carbon in waste material: $SO_4^{-2} + 2CH_2O \text{ ---> } 2HCO_3^{-1} + H_2S$.

Here a simple hydrocarbon is used as a surrogate for organic wastes. This may cause odor issues and possible health problems for workers.

For MEP some metals showed an increase in concentration in the second extraction from the first extraction. As a reminder, the first extraction of the MEP was

performed using EPTOX extraction fluid (at a pH of 5.0). The subsequent extractions were performed using a pH 3 synthetic rainwater solution. After first extraction, average pH of leaching solutions was 4.71 (after 20:1 dilution) and after second extraction, the pH decreased to 3.39. Studies have demonstrated that as pH decreases, metal desorption increases; thus, metals are more soluble under acidic conditions, which could be attributed to the tendency of metals to form soluble metal oxides in acidic environments. After second extraction metal concentrations decreased with subsequent extractions as there are less contaminant available for leaching.

5.3 Assessing Potential for Beneficial Reuse

The research presented here provides helpful information for making preliminary assessments for phosphogypsum uses. Of all the trace elements analyzed in total metal analysis test, only arsenic (UCL_{95}) was found to exceed its respective SCTL value (residential exposure). Following typical risk assessment procedures for the state of Florida, this suggests that PG cannot be land applied in a setting where direct human exposure might occur. When the SCTLs are utilized to assess risk from land application of a waste, the waste materials are assumed to be present in a manner where they replace the soil. In the case of an amendment such as PG, the waste is mixed with soil and the concentration of chemicals that an individual is exposed to is not only a function of the PG composition, but also of the background soil concentration and the rate of application (Tolaymat et al. 2008). Also PG can be used in conjunction with other materials such as coal ash for soil amendment (Lee et al. 2008). Further study with mixed materials may explore beneficial use options. One important factor in the use of phosphogypsum on agricultural lands is the possibility of radioactive element uptake by plants. Mays and Mortvedt (1986) applied phosphogypsum containing 25 pCi g^{-1} ^{226}Ra

ED_005285_00002627-00091

at rates up to 112 Mg ha^{-1} to the surface of a silt loam soil and grew successive crops of corn, wheat, and soybean. Application of phosphogypsum at a rate of 112 Mg ha^{-1} had no effect on the radioactivity levels in grain of corn, wheat, or soybeans. Analyses of soil after soybean harvest showed that the level of radioactivity in the surface 15-cm layer increased from 35 Bq kg^{-1} to 73 Bq kg^{-1}at 112Mg ha^{-1} PG rate; the radioactivity level in the subsurface layer was not affected. The 112 Mg ha^{-1} rate was more than 200 times the normal rate of gypsum used for peanut fertilization. Additionally, they noted no increases in grain Cd levels, but at the highest rate they found that corn growth slowed. They speculated that the slower growth was due to an imbalance of Ca and Mg.

PG leached Al and Fe above GWCTL in SPLP, therefore cannot be reused in Florida for land application, however, Al and Fe are secondary standards, and the other leaching tests showed low leachability of heavy metals, so beneficial use possibilities may exist under different regulatory scenarios. In fact PG can be used to alleviate Al toxicity(In soil solutions containing abundant SO_4^{2-} and F^-, Al that is not complexed with either of the ligands) from acid soil due to its precipitation and complexation reactions with SO_4^{2-} and F^-. The reduction of Al toxicity in the subsoil by PG is a result of complex set of mechanisms, including precipitation of aluminum as the result of liberation of OH^- ions from oxidic surfaces by ligand exchange with SO_4^{2-}, formation of insoluble basic Al sulfates, formation of complexes of Al with F (AlF^{2+}, AlF^+_2 and AlF_3).which are less toxic than the uncomplexed forms of Al (Carvalho and Raij 1997, Alva and Sumner 1991).

From the leaching tests (TCLP, EPTOX, MSW leaching) it can be said that none of the toxic metals that were tested in this study leached above TC limits. One potential beneficial use of PG is its utilization as part of MSW landfill construction and

maintenance activities. Other possibilities are using PG as daily and intermediate landfill cover and landfill foundation. At new landfill sites, compacted PG may be used as a substitute for the large volume of soil required to be placed under the liner to provide necessary grades. When MSW leachate contacts with PG, a few constituents of PG such as calcium and sulfate, may be considerably leached out. PG samples released considerable amount of calcium in all the leaching tests. Increased calcium concentration in MSW leachate may enhance scaling in the leachate collection and removal system. Sulfate also was considered as an easily mobile constituent from PG to MSW leachate. Increasing sulfate in MSW leachate may be a concern in terms of odor issues. On the other hand, in an anaerobic environment of landfill, PG could enhance biodegradation of municipal solid waste (MSW) in the landfill. Since PG is enriched with sulfate, it is reasonable to assume that a sulfate using bacterial colony present in landfills will use phosphogypsum as an energy source after oxygen is depleted. So use of phosphogypsum as landfill cover could enhance biological decomposition of MSW.

However, if PG is utilized as a base material under a landfill bottom liner, these issues may not be concerns because the contact of PG with MSW leachate would be prevented by the landfill liner. However use of PG, in applications where it is in contact with the MSW (either as cover material or as a direct amendment), needs to balance the potential benefits (less soil usage, greater stabilization) with the potential deleterious impacts (odors, impact on biogas collection and conversion systems). Exploration of these uses was not the main focus of this study. But results of this study can be used for the feasibility study.

ED_005285_00002627-00093

5.4 Limitations and Recommendations

In this study, leachability characterization of PG was conducted using only batch leaching test. For better understanding of PG leachability, dynamic leaching test and other batch leaching test using different pH solutions and solid liquid ratios could help evaluate how several test variables can affect leaching behavior of PG. Also leachability studies could be conducted on PG along with other materials to see how they affect leachability characteristics of PG.

CHAPTER 6
CONCLUSION

Phosphate mining in Florida is currently one of the state's largest industries, and produces approximately 40 million tons of waste material per year (Burnett et al. 1996). The total and leachable concentrations in PG were characterized for a number of metals. These data were then used to examine a variety of issues associated with determining whether the PG could be beneficially used outside of a landfill (e.g., land application as fill material, soil amendment).

Metal release was assessed using standardized batch leaching tests and additional leaching experiments using specific leaching solutions. To identify potential chemicals of concern, the concentrations of pollutants in the samples were compared with the risk-based standards. Based on the TCLP test, none of the TCLP results exceeded the regulatory toxicity limits showing PG samples did not meet the definition of EPA Toxicity Characteristic under RCRA (40 CFR Part 261.30). Note that Mercury and radionuclide were not tested in this study. However, in the SPLP tests aluminum and iron exceeded their respective Florida groundwater cleanup target levels. When MSW leachate contacts with PG, a few constituents of PG such as calcium and sulfate, may be considerably leached. Increasing sulfate in MSW leachate may be a concern in terms of increased hydrogen sulfide generation; hydrogen sulfide carries concerns of odor and potential deleterious health effects to those exposed. PG samples released considerable amounts of calcium in the TCLP, SPLP, EPTOX and in the leaching test with MSW leachate and DI water.

The TCLP and the SPLP extracted relatively similar metal concentrations (except calcium). Although arsenic was detected at high concentrations in the PG totals

ED_005285_00002627-00099

analysis, it did not leach at concentrations that may pose a risk to human health and the environment in all the leaching tests. In terms of risk assessment, from a direct human exposure pathway, arsenic was found to be the most limiting element. The SPLP results did not find arsenic to pose a risk, but has aluminum and iron concentrations above GWCTL.

It is important to examine potential impacts of PG management to the groundwater because in Florida, over 90% of residents rely on groundwater for a potable water source. Also the results of this study can assist in the consideration of land application of PG.

BIOGRAPHICAL SKETCH

Shabnam Mostary was born in Cox's Bazar, a city in Bangladesh. She started her education in Little Jewels School, and continued in Ispahani Public School and College and Chittagong College. She joined to the Civil Engineering Department at Bangladesh University of Engineering and Technology (BUET), where she got her B.Sc. Degree in January 2008. She was accepted into the graduate program in the Department of Environmental Engineering at University of Florida in August 2009. Her research interests include water, wastewater and solid and hazardous waste management. She received her ME from University of Florida in the spring of 2011.

Dan and Tom,

Here is a further revised version, Ex. 5 Deliberative Process (DP) Ex. 5 Deliberative Process (DP)
Once you review this, let me know if this looks reasonable to forward to Andrea as a clean copy.

Lee

Subject: RE: TFI One-pager and supporting materials.

I disagree with the change in the first key point. Lee has suggested the following:

Subject: TFI One-pager and supporting materials.

Hi Tom and Dan,

Sorry for the late Friday submission. You have time to look at this on Monday, no need to work over the weekend.

I have a few edits on the one-pager, and I've attached supporting references that I used for you. While there are lots of comments in the margins, I think there are not many changes.

Andrea,

We added a section of talking points, envisioning that the Administrator might be with Mosaic for some time. That took us over the one-page limit. Could you let us know what you think about this draft as well? I'd be interested if we are being presumptive in our approach.

Have a good weekend.

Hi Patricia,

Jon has cleared on the TFI package. Could you please take your editorial pen to these memorandum/letter documents, adding letterhead where needed and formatting properly? Send them back and then I can get you the whole package including that long list below for submission to CMS. We're not quite ready for CMS yet, however, so no need to look at that today.

Subject: TFI Materials for Your Review

Jon:

Attached for your review are the components of the package for approval of the TFI request for other use of phosphogypsum. Files include:

1. Transmittal Memo from you to Anne Austin, recommending that she forward the package to the Administrator;
2. Action Memo from Anne to the Administrator, recommending his signature on the approval letter and Federal Register notice;
3. Letter from the Administrator to TFI approving the request;
4. Federal Register package, including;
    - Federal Register notice for Administrator signature;
    - Typesetting request and screenshot of funding information from Compass;
    - Action Information form;
5. 1-page summary (similar to the document provided for the Administrator briefing next week);
6. Communications plan; and
7. Press release.

I believe you already have the communications plan and press release, which have also been shared with OAR communications. Charles Starrs (OGC) has provided some comment on these two documents, which will need to be reviewed with CRIO staff. Charles' comments on the other documents have been addressed.

Please let Lee or me know if you have questions or comments. Thanks.

Dan

Subject: Anything for today's management meeting?

Tom, Ingrid, Xinyue, Jon M., and Joe are in Carlsbad this week.

This week:

- Ex. 5 Deliberative Process (DP)
- We have draft materials to review for the TFI phosphogypsum application (FR and web, as well as additional TFI documentation);
- Ex. 5 Deliberative Process (DP)

Reminder that the ORIA holiday party is Thursday. Because many people are on travel this week, the RPD potluck is next week.

Anything else?

All,
I had been editing and making comments on the review file on sharepoint. Around 10 am, sharepoint crapped out on me so I had to save the working file under a different name. Please use the file with tp at the end.
Thanks.

That all sounds great. I'll put something on the calendar for Thursday afternoon.

Please have a look at the attached document, which I've been developing it for the past few weeks with the help of Joe and Stef. On Thursday I would like to talk to you about how we could use it so that you have a sense of the overall priorities, and who is responsible for individual deliverables. I'm reluctant to build a detailed schedule that goes far into the future, but I think we do need to have a clear idea of who is currently working on what, and what comes next for the overall program.

Jon

Jon,
We did the TFI meeting. A quick summary is Dave Stuenkel should be in touch with you to discuss the reclaimer issue review that we should get done before TFI comes in with their report. So, please get in touch with Dave to get this issue addressed now that the Energy Fuels immediate issue has gone up the chain.

Stefanie also said you and she talked yesterday about some major upcoming milestones and that you were going to talk with me about the current schedule. Wednesday is crowded but Thursday early or in the afternoon there is time and also on Friday if you want to set something up.

Subject: List of work projects for week of 3/23

Hi Tom,

Here are the work projects I'm working on this week:

- Working with Stefanie on a letter to the regions about confirming/updating rad NESHAPS facility info
- Continuing research on road abandonment for TFI
- COR Basic training all day on Tuesday
- Looking over case studies for LAW end of week
- Going through cross-walk talk for the DPA information on WIPP
- Continuing to reach WIPP section info and Appendix SCR/PA

Additional:

- Some of the training I would like to do as time permits is the ICS – Ex. 6 Personal Privacy (PP)

I read over the draft web page, but did not resolve any comments. I'm forwarding it, because after yesterday's conversation, we should probably look at it together with the draft FR notice to decide what direction we plan to take for the purpose of public outreach.

Should you want to make changes in earnest, the working copy is on the G: drive in the directory listed below.

David and Mike have agreed to take a look at these, as one gets pretty technical. I welcome all comments.

The SC&A report is not ready for prime time and is provided only for reference purposes.

I'd ideally like to get all comments by COB and send these questions to TFI either this evening or first thing tomorrow.

Cc: Abe Zeitoun <azeitoun@scainc.com>
Subject: Final, Clean Copy of SC&A's Review of TFI's Risk Assessment

Good morning Phil and Jon,

Attached are:

1) A final, clean copy of SC&A's review of TFI's risk assessment – Word version
2) A final, clean copy of SC&A's review of TFI's risk assessment – PDF version

3) The signed signature page from the review
4) A EPA Comment & SC&A Response matrix
5) The draft review file with EPA's comments and SC&A's responses

SC&A's technical editor edited the draft file, and I used that file as the point of departure for the final (rather than EPA's markup). We did make sure that all of EPA's comments were addressed in the final, clean copy of the review.

Thanks for the opportunity to work on this interesting project, Steve

Subject: RE: TFI files

Hi Lee,

Co-sign on all of what Dan wrote below in terms of the items I've been involved in.

OP had very minor comments on the draft FR notice that I passed onto Dan & the team last week. Also, we just need to make sure that the signature block for the Administrator should not include his middle initial since we're doing digital signatures. This would apply to Anne as well since she'll be signing the action memo transmitting the notice to the Administrator. Funding on the typesetting is good to go!

Thanks,

Ray

Subject: RE: TFI files

We should be aware that some changes may need to be made after the OLEM meeting tomorrow.

OP provided comments on the FR last week, which Ray indicated are minor. I have not incorporated them yet.

I believe Tom may have been revising the Action Memo. Will check with him tomorrow to see if he had changes other than the names.

The Action Information should be good. You made the changes to the stakeholder section and Tom and I agreed.

The letter needs some revision. I have asked Patricia to chase down standard language for the Administrator's correspondence. There are about a half-dozen places where it has some variation of "I approve" that should probably be changed. I also want to do some slight revision in one place for clarity. And there are a couple of formatting things.

The 1-pager, comms plan, press release, and typesetting information are fine from my perspective.

Subject: TFI files

Hi Dan and Ray,

This is the last copy of the FR notice that I have related to the TFI project, along with all the files that I have that are in final. I'd like to confirm with you a few items and ask for any other changes/corrections:

1. Action Memo from Anne Austin to the Administrator (this was previously from JE to AA). I made the modification under the To and FROM sections. Please confirm this is good to go.
2. TFI Approval 1-pager (was 8 27 2020 now 09 14 2020) I made the change to the bottom line indicating that our recommendation was for the Administrator to sign (not the PDAA).
3. TFI Press Release. This is from Stefanie's email to me on Friday, 9/11.
4. TFI Communications Plan. This is from Stefanie's email to me on Friday, 9/11.
5. TFI FR. Is this the latest? I left this for Anne's signature, and made one change to the footnote that references the approval letter (from Administrator not PDAA). Dan mentioned that Ray Lee may have had a few changes, so let me know if this is the final please.
6. TFI Approval Action Information Form (was 8 27 2020 now 09 14 2020). There were still some redline marks on the Stakeholder Involvement section. I accepted those changes. Let me know if this is final.
7. Response to TFI- Letter PDAA to TFI. I included all the comments that I had from OGC (per Charles' email) but I have not made changes to the signature line or language to reflect that the Administrator will sign. Dan S/CWMR has the pen and will work with Charles. I include it here for reference.
8. Two pdfs, -the typesetting request and the accounting screen. These are from Ray Lee and PMO.

Subject: WA 6-20 Draft Work Plan and QAPP

Phil and Jon,

Attached are the draft Work Plan and QAPP for WA 6-20 "Technical Review of the Fertilizer Institute Petition and Risk Assessment for Additional Use of Phosphogypsum in Road Base".

We're looking forward to discussing these draft documents with you during next Monday's 2 pm teleconference. After that we'll make any changes necessary, and send the finalized documents to EPA.

Steve

Subject: RE: Additional Info please

Preparing a table to summarize the specific statements TFI is making in its request, either what it is asking for approval on or what constraints it will place on the use of phosphogypsum in road construction. This will be used in conjunction with the technical analysis and OGC input to define our options for responding to the request, including identifying terms and conditions. We anticipate briefing Anne Idsal on the options at the end of the month.

Subject: Anything for today's management meeting?

Tom is on leave today. I will be at DOE in Germantown most of tomorrow, and teleworking otherwise.

Things going on this week:

- Final preparations for WIPP trip next week;
- Working on a 1-pager for the MOU with NRC;
- Working on a Federal Register notice for the TFI phosphogypsum application;
- WIPP inspection reports hopefully clear CWMR review this week;
- SNL baseline FR notice published last Wednesday (45-day comment period).

Anything else?

Hi Patricia and Charlene,

Could you please help us get this onto letterhead and it proper format for me? I think that this might be Joe's first official technical analysis memo that I've seen (as an EPA employee).

Could you double check all page numbering (for the 3 attachments), margins, headers, etc to ensure it meets EPA correspondence manual requirements? We are going to make this available in the public docket, so it will have to represent!

Thank you in advance.

Lee,
Attached are the latest versions of the technical review and road abandonment documents (guys, please confirm).

The technical review document (Sept. 30 version) has one last comment from me that you need to decide on and there is the draft watermark that needs to be deleted once you are done.

Dan and I looked at the road abandonment memo and Joe has addressed our comments.
