1.0 INTRODUCTION

AMEC Environment & Infrastructure, Inc. (AMEC) (formerly MACTEC Engineering & Consulting, Inc. (MACTEC)) has prepared this Final Baseline Human Health Risk Assessment (BHHRA) on behalf of BASF Corporation (BASF) for Operable Unit 1 (OU1) and Operable Unit 2 (OU2) of the CPS/Madison Superfund Site, located in Old Bridge Township, Middlesex County, New Jersey (**Figure 1-1**). OU1 includes groundwater and OU2 includes soils at the Former CPS Facility. The Former CPS Facility (the Property), which consists of the CPS Plant Parcel and the CPS Side Lot Parcel is a 35-acre property. The Madison Industries Facility is located adjacent to and west of the Former CPS Facility. Both properties comprise the CPS/Madison Superfund Site (**Figure 1-2**).

The purpose of this BHHRA is to characterize the potential health risk associated with potential exposure to impacted environmental media by receptors associated with current and foreseeable future land uses, in the absence of further remediation. This BHHRA addresses soils at Area 1 (the former tank farm – also called AEC-5), Area 2 (the former plant area – also called AEC-1)), and Area 3 (the side lot) of the CPS Facility (**Figure 1-3**), groundwater beneath and down gradient of the Site, groundwater/surface water interaction, and indoor air (potentially associated with vapor intrusion) at the former CPS Facility and the Madison Industries Facility. The BHHRA evaluates soils at the former CPS Property, the vapor intrusion pathway at the former CPS Property and the Madison Industries Property, and groundwater at the former CPS Property, the Madison industries Property, and the downgradient Runyon wellfield.

This BHHRA is required by the Administrative Order on Consent (AOC) entered into by Ciba Specialty Chemicals Corporation (Ciba; acquired by BASF in April 2009) and the United States Environmental Protection Agency (USEPA) Region 2 on October 5, 2005 (USEPA, 2005a), and the associated Statement of Work (SOW) (USEPA, 2005b). BASF is not responsible under the AOC for conducting Remedial Investigation/Feasibility Study (RI/FS) activities for metals in media other than groundwater. This BHHRA evaluates metals and constituents other than volatile organic compounds (VOCs) in Site media for the purpose of completely characterizing the risks associated with media impacted by CPS-related contaminants of potential concern and better understanding the remedial alternatives and/or opportunities to repurpose the property (or portions thereof).

1.1 Regulatory Context of Human Health Risk Assessment

BASF is conducting an RI/FS under an AOC and associated SOW as described above. The AOC and SOW were developed per the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). The applicable regulatory requirement is the National Contingency Plan (NCP), 40 CFR Part 300.

The AOC and SOW identify requirements for OU1 (groundwater) and OU2 (soils at the former CPS Facility) and OU3 (soils at the Madison Industries Facility) [not included in this BHHRA]. This BHHRA specifically addresses the human health risks associated with OU1 and OU2.

A complete list of regulation, guidance and policy documents that have been relied upon to complete the BHHRA is included in the References List in Section 8.0 of this BHHRA. Specifically, the BHHRA is performed using USEPA CERCLA guidance for risk assessment, including, but not limited to the USEPA risk assessment guidance and directives listed below:

- Risk Assessment Guidance for Superfund (RAGS). Volume 1: Human Health Evaluation Manual (Parts A, D, E and F) (USEPA, 1989; 2001; 2004; 2009)
- Exposure Factors Handbook (USEPA, 1997a, 2011)
- Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites (USEPA, 2002a)
- Calculating Upper Confidence Limits (UCLs) for Exposure Point Concentrations (EPCs) at Hazardous Waste Sites (USEPA, 2002b)
- Human Health Toxicity Values in Superfund Risk Assessments (USEPA, 2003)
- Guidelines for Carcinogen Risk Assessment, Final (USEPA, 2005c)
- Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005d).
- USEPA Vapor Intrusion Screening Level Calculator, User's Guide (USEPA, 2013a)

1.2 Content of the Human Health Risk Assessment

The BHHRA is completed using a four-step process, consistent with the framework for risk assessment described in *RAGS* (USEPA, 1989). The four steps include Data Evaluation and Selection of Chemicals of Potential Concern (sometimes also referred to as Hazard Identification), Exposure Assessment, Toxicity Assessment, and Risk Characterization. Supporting documentation of the risk assessment methods, inputs, and results are provided in tables, figures, and appendices to the document. The organization of the BHHRA and content of each of the report sections is described below.

The remainder of Section 1.0 provides the Site description, remedial investigation summary, the conceptual site model (CSM) from a physical perspective and from a human health risk assessment perspective (nature and extent of contamination and fate and transport, identification of receptors, exposure media, and exposure pathways). **Tables 1-1** through **1-5** (Vapor Intrusion evaluation), **Attachment A** (analytical data tables), and **Attachment B** (contaminant distribution figures) support the discussion of the CSM. **Figure 1-1** provides the Site location, **Figure 1-2** provides the overall CPS/Madison Superfund Site layout, and **Figure 1-3** provides the CPS Facility (the Site) layout. **Table 1-6** provides 'RAGS Part D, Table 1', which is the 'road map' for the risk assessment and the basis for the grouping of analytical data described in Section 2.0 and the exposure assessment described in Section 3.0.

Section 2.0, Data Evaluation and Identification of Chemicals of Potential Concern summarizes and documents the evaluation of existing data and the development of the data sets used in the BHHRA and documents the selection of the chemical parameters that are evaluated in the BHHRA (Chemicals of Potential Concern (COPCs). The culmination of the data evaluation is the

identification of COPCs for each of the OU1 and OU2 media. The selection of COPCs is documented in tables and text. **Tables 2-1** through **2-4** present the COPC selection tables for the HHRA. **Attachment A** presents the analytical data considered in the BHHRA.

Section 3.0, Exposure Assessment, provides information documenting the human populations that could access or use the Site under current and possible future land use conditions, discusses how those populations could potentially be exposed to the COPCs in Site media, and quantifies how much exposure could occur (not required for this Pathway Analysis Report – to be included in the Draft BHHRA RAGS Part D Table 7s and 9s)). Specific components of the Exposure Assessment include descriptions of current and future land uses and receptors, exposure areas (EAs), exposure pathways, and exposure scenarios, and documentation of exposure point concentrations (EPCs) and exposure intake calculations (latter to be provided in the Draft BHHRA RAGS Part D Table 7s and 9s). **Tables 3-1 through 3-15** document the exposure point concentrations for media and scenarios evaluated. **Tables 3-16 through 3-20** document the exposure parameters utilized in the exposure assessment. **Attachment C** (groundwater/surface water interaction evaluation), **Attachment D** (vapor intrusion evaluation), and **Attachment E** (site photographs) support both the CSM discussion and the exposure assessment discussion. **Attachment F** provides supporting documentation for calculation of EPCs using USEPA Pro-UCL software.

Section 4.0, Toxicity Assessment, provides information concerning the toxicological attributes of COPCs and the dose-response relationships of the COPCs that are used to quantify health risks. **Tables 4-1 through 4-6** document the toxicity values utilized in the BHHRA.

Section 5.0, Risk Characterization presents the methodology used to calculate and summarize health risks, as well as the results and interpretation of the calculated risks. RAGS Part D Table 7s and RAGS Part D Table 9s will present the RAGS Part D tables that collectively provide the documentation of risk calculations. **Tables 5-1 and 5-2** summarize the calculated human health risks. RAGS Part D Table 7s and Table 9s included in **Attachments G and H** document the human health risk calculations.

Section 6.0 presents an uncertainty analysis, which provides an evaluation of the data evaluation, exposure assessment, toxicity assessment, and risk characterization variables, assumptions, and decisions that could or may have affected the results of the risk assessment.

Section 7.0 provides the summary and conclusions of the BHHRA. The results are presented in the context of CERCLA risk management criteria.

Section 8.0 documents references utilized in the preparation of the BHHRA.

1.3 Site Description

The former CPS Property consists of two parcels of land (as indicated on **Figure 1-2**) located on Old Water Works Road, Old Bridge Township, New Jersey and covers approximately 30 acres. The CPS Plant Parcel contained the plant production areas and the adjacent parcel that is a largely undeveloped side lot. The developed portion of the CPS Site is approximately 6.7 acres and the undeveloped portion is approximately 21.3 acres (Ciba, 2008). The CPS Site is further

subdivided into three sub areas (Area 1, Area 2, and Area 3), which represent the former tank farm area, the former plant area and the side lot, respectively (**Figure 1-3)** (BASF, 2011).

In December 2001, the CPS Chemical plant had ceased commercial operation and by November 2005 the structures associated with the plant operations had been demolished. Except for the former tank farm area, which is currently an unpaved water-filled depression, areas with soil, cement and paving remain intact, although some asphalt surfaces were damaged during demolition. The former CPS Plant parcel (Areas 1 and 2) is about 95% paved with asphalt or concrete. The CPS Side Lot area (Area 3) is 100% unpaved, and it is the location of the groundwater recharge basin as shown in **Figure 1-3** (BASF, 2011).

The only current use of the CPS property is operation and maintenance of a groundwater extraction and treatment system. There are two small pump houses and a treated groundwater discharge basin associated with this system. The property is improved with a currently unoccupied former lab/warehouse/office building located at the northwest corner of the CPS property. There is an open-air storage structure (roof only) located immediately south of that building. There is also a temporary field trailer on-site that is used by employees involved with operation and monitoring of the groundwater treatment system and investigation activities. Currently, there are no full-time employees at the property. (BASF, 2011)

The Interim Remedial Measure (IRM) treated groundwater discharge basin is located in the northern portion of the CPS property side lot. That basin is currently inaccessible due to an 8-foot (ft) chain link fence. A subsurface municipal sewer line traverses the property from the southwest to the northeast. Refer to **Figure 1-3** for the locations of these features.

The approximately 30-acre property as well as most of the surrounding area is zoned SD3, Specialized Development for industrial land use as part of the Township's long term development plan, and therefore it is unlikely that these areas will be used in the future for residential development. The former CPS Site was previously used for industrial purposes and although it is currently unused, it is likely that future use will be industrial.

There are no definitive foreseeable plans for the former CPS Site; however, if possible, BASF would like to put into productive use both Area 2 (the former plant area outside the former tank farm area) and Area 3 (the side lot). Areas 2 and 3 generally contain lower levels of contamination than does Area 1 (the former tank farm). Future use(s) of these areas will likely be industrial (BASF, 2011).

The CPS property is bordered to the north by Old Water Works Road, to the west by the Madison Industries property, the properties south and east of the Site are undeveloped and the closest residence is approximately ½ mile northeast of the property.

With regard to surface water, **Figure 1-3a** provides the stormwater conveyance structures across the CPS property. There are two primary drainage channels. One bisects the property from north to south. The other traverses the southern property line, and it connects the upland watershed with Prickett's Brook to the west. While this drainage feature has been referred to as Prickett's Brook, a stream segment is not included on the USGS topographic map (Figure 1-1, 1981) or the NJDEP GeoWeb GIS stream layer. Both features carry water only during significant storm

events and during high groundwater table conditions. Figure 1-3a also shows two areas of ponded water. The ponded water in Area 3 is associated with the groundwater P&T system (recharge basin). The ponded water in Area 1 is associated with an anthropogenic depression that resulted from demolition of the former tank farm (carries water during significant storm events and during high groundwater elevation conditions).

The brook is not used for recreational purposes on the Madison property nor in the downstream portion of the brook that flows through a wooded area between the Madison Industries property and Prickett's Pond. Prickett's Pond was created as a recharge basin for the Runyon well field and it is not used for recreational purposes. The Perth Amboy municipal water supply Runyon Supply Wells are located approximately 3,000 ft. southwest of the CPS property.

Madison Facility Property

The adjacent Madison Industries Facility property is 10 acres in size and remains an active chemical manufacturing facility. The property is paved, fenced, and has 24-hour security (ATSDR, 1998). The Remedial Investigation Report (BASF 2013) provides additional information concerning environmental impacts at that property.

Prickett's Brook and Pond, Tennent Pond, and the Runyon Well Field

The following description of the Prickett's Brook and Pond, Tennent Pond, and The Runyon Well Field, has been summarized from the ATSDR Public Health Assessment (ATSDR, 1998). The City of Perth Amboy well field, known as the Runyon Watershed, is located directly south-southwest and down gradient of the CPS/Madison Superfund Site. The Perth Amboy well field supplies the water mostly for the cities of Perth Amboy and South Amboy. The majority of the water serving Perth Amboy is drawn from the Old Bridge Sand aquifer near the southern end of Tennent Pond. Part of the Perth Amboy well field includes two recharge ponds, Tennent Pond and Prickett's Pond. These ponds were specifically created to enhance groundwater recharge to the supply wells. Local surface-water drains to the southwest across the study area: Prickett's Brook flows from the Madison Industries facility into Prickett's Pond. Prickett's Pond drains into Tennent Brook, which in turn, serves as a recharge basin for Tennent's Pond. Tennent's Brook then flows northwest, joins the South River, and empties into the Raritan River ultimately emptying into the Raritan Bay. Prickett's Brook acts as an eroding stream transporting and depositing suspended material into Prickett's Pond. (ATSDR, 1998).

1.4 Remedial Investigation Summary

A summary of the investigations and activities performed to generate the analytical data to support this HHRA are presented in the Remedial Investigation (RI) Report (BASF, 2013). The RI Report relied on analytical data generated during a Supplemental Remedial Investigation (SRI) which was performed pursuant to an October 5, 2005 AOC entered into by Ciba Specialty Chemical Corporation (Ciba) and the USEPA Region 2. The findings of the SRI were presented in the Site Characterization Summary Report (SCSR) (BASF, 2011). In 2012, BASF defined and completed final elements of the SRI work scope. Upon completion of that additional work, BASF concluded that the work performed had generated the data sufficient to complete the Risk Assessment tasks and initiate the FS portion of the project. Refer to Section 3.2 of the RI Report for a summary of the Remedial Investigation activities and findings (BASF, 2013).

1.5 Conceptual Site Model (CSM)

A CSM is used to describe the potential migration pathways through which Site-related contaminants may have been transported and/or trans-located from source or release areas at the Site to other environmental media where possible human and environmental exposure may occur. The potential human receptors and exposure pathways are discussed below in the context of the physical CSM. **Figure 1-4** presents Figure 16 excerpted from BASF (2013) and depicts a cross-sectional CSM for the CPS/ Madison Superfund Site. Sources, impacted media, migration pathways, receptors, and routes of exposure are discussed in the following sections. **Figure 1-5** presents this discussion summarized in a Human Health Risk Assessment Conceptual Site Model Figure.

1.5.1 Sources

At the CPS Facility, releases occurred within Area 1 (**Figure 1-3**) in the former tank farm area (called AEC-5 in previous reports) and in the former truck and railroad car loading area (called AEC-1 in previous reports). In the former Tank Farm area, activities related to solvent recycling and the storage and use of chemical raw materials likely resulted in releases to soil and subsequently to groundwater. As reported in the RI Report, "The VOCs detected in former tank farm area soils include: 1,2,4-trichlorobenzene; 1,4-dichlorobenzene; 1,2-dichlorobenzene; chlorobenzene; benzene; toluene; xylene; tetrachloroethene PCE); trichloroethene (TCE); methylene chloride; 1,1,2,2-tetrachloroethane and 1,2-dichloroethane. In addition, a few semivolatile organic compounds (SVOCs), including polynuclear aromatic hydrocarbon (PAH) compounds, were detected at low concentrations in shallow AEC-5 [Area 1] soils" (BASF, 2013). Delineation and sampling conducted during the SRI Phase 2 indicated that 1,4-dioxane had been released to groundwater in the vicinity of the former truck and railroad car loading area (BASF, 2013). The extent of this release was identified on Figure 13 of the RI Report, and the location of the former truck and railroad car loading areas is identified on **Figure 1-3.** As reported Section 3.2.8.1 of the RI Report, "1,4-dioxane was detected at 15 of the 23 locations within the sampling grid at concentrations up to 650 ug/L in the shallow groundwater samples. Deeper groundwater samples (14'-16') (see Appendix F6) showed much lower concentrations (non-detectable at 15 locations, maximum detection 170 ug/L). The maximum concentrations in the deeper samples were noted at the same locations where the shallow sample concentrations were highest. Based on the pattern of detections and range of concentrations, it appears that the 1,4-dioxane detected during the IRM Assessment sampling on the Madison Site originated in the AEC-1 area[1]." (BASF, 2013)

At the Madison Facility, located hydraulically downgradient of the CPS facility, operations have historically been associated with the manufacture of sulfates and chlorides of zinc and other select inorganic constituents. In addition to zinc, three other inorganic constituents (cadmium, copper and lead) have been associated with site operations. Manufactured products consist of edible forms of copper and zinc, used as nutritional supplements. In addition, cadmium and lead are acknowledged to be associated with past facility operations. Raw materials containing zinc, lead,

[1] former truck and railroad car loading area, see Figure 1-3.

and cadmium were historically stored in outside piles (no longer present) on the site. As reported in the RI Report, during the years between 1970 and 1979, a series of nine major storage tank spills (zinc sulfate and zinc chloride solutions) occurred with approximately 80,000 gallons of material lost. These major spills, combined with incidental spills, drips and leaks, have contributed to contamination of the underlying aquifer (BASF, 2013).

As reported in the RI Report, "The Evor Phillips Leasing Company property (EPLC Site), located northeast of the CPS/Madison Site, was leased to a variety of industrial operators between 1970 and late 1974. Activities conducted on the site during that timeframe reportedly included waste hauling/treatment/storage and disposal (including acid neutralization), precious metal reclamation, and waste-oil recovery. Two onsite treatment ponds formerly used for the neutralization of acidic and caustic wastewater were reportedly closed in 1975 with NJDEP approval." Drums and underground storage tanks (USTs) have been removed and impacted soils have been excavated and removed from the site. The locations of those removals are considered to be the former chemical release source areas at the EPLC Site. Groundwater at the EPLC Site has been impacted by several chlorinated VOCs as well as benzene, ethylbenzene, and xylenes (BASF, 2013). Groundwater interim remedial measures implemented under USEPA oversight resulted in marked decreases in groundwater VOC concentrations on the EPLC site and in downgradient areas. A final groundwater remedy is being designed which will address remaining VOC impacts related to EPLC. Based upon EPLC data, since about 2003, mass flux from the EPLC site has been negligible, and CPS/Madison data collection does not currently detect a significant contribution from EPLC.

1.5.2 Impacted Media and Potentially Receiving Media

1.5.2.1 Soil

The nature and extent of contamination at the Site has been presented and discussed thoroughly in numerous documents previously submitted to New Jersey Department of Environmental Protection (NJDEP) and USEPA, and most recently in the February 2013 Draft *Remedial Investigation Report, CPS/Madison Superfund Site, Old Bridge, Middlesex County, New Jersey EPA I.D. Number: NJD002141190 (BASF, 2013)* and the October 2011 *Site Characterization Summary Report, CPS/Madison Superfund Site, Old Bridge, Middlesex County, New Jersey* (BASF, 2011). The summary of site investigation activities and the findings of each sampling/analysis event are, therefore, not repeated here.

The former CPS Property has been delineated into three sub-areas based on historical land use and hydrology (**Figure 1-3**). Area 1 is where chemical processing operations occurred, and it is located hydraulically downgradient or side-gradient of both Areas 2 and 3. Area 2 is associated with support activities including laboratory and office space and storage facilities. Area 3 is undeveloped and has never been used for production activities. Sand and gravel excavation took place throughout this portion of the property prior to 1977. As a result, the area is flat-lying and poorly drained and devoid of trees.

Figure 1-6 identifies the RI soil sampling locations within Areas 1, 2, and 3. In **Attachment A**, **Tables A-1, A-2, and A-3** summarize the surface soil analytical data and present sample results for individual samples for Areas 1, 2, and 3. Each of those tables presents the frequency of

detection, range of reporting limits, range of detected concentrations, and the arithmetic mean concentration for all samples collected within 2 feet of the land surface. **Tables A-4, A-5, and A-6** present the same information for soil within 10 feet of land surface. **Table A-7** presents the soil analytical data in close proximity to the sewer line that runs through the property. The human health risk assessment has considered soils within the top 10 feet of the soil column as potentially accessible to human receptors. In addition, each of these tables presents all of the analytical data for the samples considered in the human health risk assessment for that particular exposure area.

The data summary indicates that 56 VOCs, 36 SVOCs, three polychlorinated biphenyls (Aroclor-1260, Aroclor-1248, and Aroclor-1254), and 23 inorganics/metals have been detected in at least one soil sample. The most frequently detected VOCs in soil (in decreasing order of number of detections) are toluene, acetone, xylenes, ethylbenzene, chlorobenzene, 1,2-dichlorobenzene, 1,4-dichlorobenzene, benzene, methylene chloride, 1,3-dichlorobenzene, 1,2,4-trichlorobenzene, 1,2-cis-dichloroethylene, trichloroethene, tetrachloroethylene, 1,2-dichloroethane, 1,1,2,2-tetrachloroethane, 1,2,3-trichlorobenzene, tetrachloroethane.. The most frequently detected SVOCs are bis(2-ethylhexyl)phthalate (BEHP), chrysene, fluoranthene, pyrene, phenanthrene, fluorene, benzo(b)fluoranthene, biphenyl, benzo(a) pyrene (B(a)P), biphenyl, benzo(a)anthracene, benzo(ghi)perylene, benzo(k) fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, 2-methylnaphthalene, and fluorene. The PAHs are commonly detected in soils in urban and suburban environments. Many inorganic and metal constituents were detected with high frequency in soil samples (aluminum, arsenic, barium, beryllium, cadmium, calcium, cobalt, copper, iron, lead, magnesium, manganese, nickel, potassium, vanadium, and zinc. Most of these constituents are naturally occurring and several (e.g., zinc, copper, cadmium, lead) may in part be attributable to historical Madison Industries operations.

1.5.2.2 Groundwater

The area of groundwater that is particularly relevant for the CPS/Madison Superfund Site includes the following: the Evor Philips Superfund site located to the northeast of the CPS site; the CPS Site; the Madison Site, and the Runyon Wellfield property (ground water supply for Perth-Amboy) to the southwest of the CPS and Madison Sites. **Figure 1-2** depicts the general locations of these sites. Overburden groundwater naturally flows generally in a northeast to southwest direction from the Evor Philips Site, through the CPS and Madison Sites, and toward the Runyon Wellfield property to the southwest.

As per the SOW (USEPA, 2005), BASF is responsible for conducting groundwater RI/FS activities only for contamination originating on the CPS and Madison sites. **Figure 1-7** provides the soil gas and indoor air sampling locations. **Figure 1-8** identifies the shallow groundwater sampling locations within the CPS Site. **Figure 1-9** identifies the groundwater sampling locations used to characterize CPS/Madison groundwater impact. **Attachment A Table A-8** summarizes the analytical data and presents sample results for individual characterization samples for groundwater (the plume). **Attachment A Tables A-9 through A-11** summarizes the analytical data and presents sample results for individual samples for shallow groundwater within Area 1, 2, and 3. Each of these tables presents all of the analytical data for the samples considered in the human health risk assessment for that particular exposure area (construction worker exposure to shallow groundwater).

The RI report also discusses groundwater impacts associated with the upgradient Evor-Philips Site and other potential sources of groundwater contamination. The following text describes the chemical impacts to groundwater associated with the sources at Evor-Philips, CPS, and Madison.

As described in the 2013 RI Report, CPS chemicals of interest (COIs) that result in an extensive groundwater distribution (outside the CPS source area) have been grouped and referred to as CPS groundwater COIs. The CPS groundwater COIs include: 1,2,4-trichlorobenzene; chlorobenzene; benzene; methylene chloride; 1,1,2,2-tetrachloroethane; 1,2-dichloroethane; 1,1-dichloroethene; tetrachloroethene; trichloroethene; cis-1,2-dichloroethene; vinyl chloride and 1,4-dioxane. Five compounds, are present only in the former tank farm area: 1,4-dichlorobenzene; 1,2-dichlorobenzene; toluene; 1,2-dichloropropane; 1,1,2-trichloroethane. Figures 25A through 28A of the RI Report (copies included in **Attachment B**) present the groundwater concentration distributions for 1,2,4-trichlorobenzene, chlorobenzene, benzene, and 1,4-dioxane, respectively.

As discussed in the 2013 RI Report, Madison Industries' operations have included use and onsite storage of materials containing cadmium, copper, lead and zinc. Madison industries is required to analyze these metals for their groundwater monitoring. Therefore, cadmium, copper, lead and zinc are referred to Madison COIs.

The Evor Philips Site plume constituents include 1,2-dichloroethane, trichloroethene, cis-1,2-dichloroethene, methylene chloride (the primary VOCs indicative of spatial extent of the Evor Philips-related plume), carbon tetrachloride, chloroform, 1,1,2,2-tetrachloroethane, tetrachloroethene, 1,1,1-trichloroethane, and vinyl chloride.

The City of Perth Amboy's municipal well field (Runyon Wellfield) is located approximately 3,000 feet south-southwest of the CPS Facility property. Since 1991 both the CPS and Madison properties have operated and maintained groundwater pumping and treatment interim remedial measures to protect the Runyon Wellfield from potential impacts from Evor Philips, CPS, and Madison COIs in groundwater.

Wells #5 and #6A are the only Runyon wells (see **Figure 1-9**) that have been affected by CPS COIs, and detected concentrations have been below the federal and NJ drinking water drinking water standards since September 1999, when benzene was detected at 1.2 micrograms per liter (µg/L) in Well #6A. Over the last ten years VOCs have been periodically detected in raw water samples at levels below applicable drinking water standards (both CPS COIs (chlorobenzene, benzene, 1,4-dichlorobenzene, 1,2-dichloroethane, cis-1,2-dichoroethene, toluene, and trichloroethene) and compounds not related to CPS (chloroform, chloromethane, methyl tert-butyl ether, and tert-butyl-alcohol)). Madison COIs (lead and zinc) have been detected in raw water samples from Wells #5 and #6A, but never at concentrations above drinking water standards.

Since 1991 flow of groundwater and associated CPS and Madison contaminants have been mitigated by interim remedial measures (pumping and treatment). Since 1996, both CPS and Madison have been operating local interim remedial measures (IRMs) to control site-related groundwater contamination at the respective property boundaries. Since 1999, EPLC has been operating a pump and treat (P&T) system to control its groundwater impacts. As reported in BASF (2013), there are two operating remediation wells at the Evor Philips Site, two operating remediation wells at the CPS Site, and ten operating remediation wells at the Madison Site. The

remediation wells at the CPS and Madison Sites "collectively intercept most of the groundwater flowing through source areas" on those two sites and the Runyon Wellfield is not significantly impacted.

1.5.2.3 Surface Water and Sediment

The hydrology and the nature and extent of contamination in Prickett's Brook, Prickett's Pond, and Tennant Pond are discussed in the RI Report (BASF, 2013). Prickett's Brook is an intermittent stream upstream and adjacent to the CPS and Madison Sites that supports water only during significant stormwater events and high groundwater table conditions. The report indicates the brook is a losing stream as it passes through the Madison Site and is a gaining stream (groundwater discharge) downstream of the Madison Site. There is groundwater discharge at the northern-most portion of Prickett's Pond. In the lower portions of Prickett's Pond and the downstream portion of Prickett's Brook there is groundwater recharge (stream loss). Given this information, there is a potential for migration of constituents in groundwater to surface water and sediment of Prickett's Brook and Prickett's Pond.

In order to evaluate the potential impact of impacted groundwater discharging to the surface water bodies and to evaluate the need for surface water/sediment sampling and analysis, a groundwater / surface water interaction study was implemented. This study involved the installation of temporary piezometers at 14 locations in Prickett's Brook and Pond, measurement of elevation of groundwater within the piezometers and the surface water adjacent to each piezometer (determination of vertical gradient), and collection of groundwater samples from each piezometer for chemical analysis (VOCs, SVOCs, and total and dissolved metals). A comparison of groundwater sample analytical results for VOCs and SVOCs to ecological and human health surface water screening criteria (trespasser dermal contact and incidental ingestion of surface water) was performed. The information from the RI Report groundwater/surface water interaction study is presented as **Attachment C** to this BHHRA. No groundwater VOC or SVOC (CPS COIs) concentrations in areas of discharging groundwater were above ecological or human health screening criteria based on a potential recreational scenario. Based on these data, and the CSM for contaminant transport (in particular that the source for VOC contamination is controlled by the IRMs), it was concluded that VOCs and SVOCs in discharging groundwater would be unlikely to produce adverse impacts to ecological or human receptors now or in the future and that sampling and analysis of surface water and sediment for CPS COIs is not necessary.

Analytical data from GW-SW-3, GW-SW-4, GW-SW-5, GW-SW-6, and GW-SW-7 (locations where groundwater was determined to upwell to surface water during the groundwater / surface water interaction study) were used to conservatively estimate surface water quality in the COPC screening performed in this BHHRA. Refer to Section 2.3 for a discussion of this evaluation.

1.5.2.4 Potential Vapor Intrusion Media (groundwater/soil vapor/indoor air)

The reported presence of VOCs in soil at and groundwater beneath the CPS and Madison properties indicates the potential for migration of vapors from soil and or groundwater to soil vapor into indoor air of occupied or potentially occupied buildings. Several activities have been conducted to evaluate the vapor intrusion pathway and potential impacts to soil vapor and indoor air. Those activities include:

- Vapor intrusion (VI) investigation at the CPS property in 2009 per NJDEP procedures and screening values;
- Vapor intrusion investigation at the Madison property in 2009 per NJDEP procedures and screening values;
- Updates to the evaluation of results for the 2009 CPS and Madison property VI investigations using updated 2013 NJDEP groundwater, soil vapor, and indoor air screening levels (NJDEP, 2013a);
- Updates to the evaluation of results for the 2009 CPS and Madison property VI investigations using 2013 USEPA Vapor Intrusion Screening Criteria Levels (VISLs) presented in the VISL Calculator (USEPA, 2013a) for a commercial scenario and the USEPA Region 2 VI Matrix approach;
- Screening of shallow groundwater data from Areas 1, 2, and 3 of the CPS property using USEPA VISL groundwater screening levels (GWSLs).
- Evaluate information from multiple lines of evidence concerning the need for any further evaluation of the VI pathway.

2009 Vapor Intrusion Investigation CPS Property and Subsequent Updates

VI investigations were conducted on the CPS property as described in the On-Site Vapor Intrusion Investigation Report (MACTEC, 2009a) which is included as Appendix E of BASF (2013) and as **Attachment D-1** to this risk assessment submittal). The CPS property ("On-Site") Vapor Intrusion Work Plan was approved by USEPA on June 3, 2009. The On-Site VI investigation involved the comparison of groundwater data to NJDEP vapor intrusion-based GWSLs, collection of soil vapor samples, comparison of the soil vapor results to NJDEP soil gas screening levels (SGSLs), and collection and analysis of indoor air samples (On-Property) as necessary.

The On-Site VI investigation (September 2009) included collection of co-located soil gas (Summa canisters) and indoor air (Summa canisters) samples within the unoccupied office, laboratory, and warehouse portions of the existing building at the CPS Site and submittal of samples for laboratory analyses of VOCs using Method TO-15. **Figure 1-7** presents the locations of the soil gas and indoor air samples. Three ambient air samples (two within the building on stairwell landings and one outdoors upwind of the building) were also collected and analyzed via Method TO-15. Indoor and outdoor air samples were collected on day one of the investigation. The sub-slab soil vapor probes were installed on day 2 and they were sampled on day 3 of the investigation. Sub-slab samples were collected from 6" double screened stainless steel vapor sampling implants, packed in sand, sealed with bentonite, and fitted with 3" aluminum flush mounts that were set in place with concrete. The implants were leak tested using helium prior to sampling.

As part of the On-Site VI Investigation, the 2009 data were evaluated with respect to the NJDEP SGSLs and Indoor Air Screening Levels (IASLs) (published in 2007) to determine the need for further investigation or action in accordance with NJDEP VI Guidance and Decision Matrix Flow Chart. Indoor air sample results were also evaluated with respect to the Rapid Action Levels (RALs) to determine the need for any immediate action. The report concluded the following: VOCs were not detected above the RALs in any of the indoor air samples and no VOCs were detected above applicable screening levels in both the sub-slab soil gas and indoor air samples. Some

VOCs were detected above NJDEP SGSLs in soil gas samples (i.e., chloroform, PCE, and benzene), but were not detected in indoor air samples, indicating that the VI pathway is not complete for these compounds. VOC concentrations in all indoor air samples were below the NJDEP IASLs, with the exception of the MTBE concentration in IA-01. This exceedance is likely associated with background or other sources, such as the gas powered equipment stored in this area of the warehouse. MTBE was not detected in the associated soil gas sample, indicating that this compound is not attributable to the VI pathway. A copy of this VI evaluation is included in **Attachment D-1**.

Based on the VI investigation findings and review of data with respect to NJDEP screening levels and VI Guidance/Decision Flow Chart, it was determined that there was no immediate adverse health risk or rapid response action required at the time. Based on the lack of correlation of soil gas and indoor air results, and potential contribution from other sources (i.e., gas powered equipment), no further action was recommended for the On-Site VI Investigation.

The BHHRA First Interim Deliverable included an update to the On-Site VI Investigation due to recent NJDEP updates to the Vapor Intrusion Guidance (NJDEP, 2013b) and the associated NJDEP March 2013 IASLs and SGSLs (NJDEP, 2013a). This comparison was presented as Table 2 in the BHHRA First Interim Deliverable and is included in **Attachment D-3**. The update to the On-Site VI investigation, consistent with the NJDEP VI Guidance, evaluated multiple lines of evidence to determine appropriate action for the VI pathway for the office, laboratory, and warehouse portions of the existing building. Based on the VI investigation findings and review of data with respect to NJDEP screening levels and VI Guidance/Decision Flow Chart, the conclusions documented in the 2009 VI investigation were confirmed; no VOCs were detected above applicable screening levels in both the sub-slab soil gas and indoor air samples. Chloroform was detected above the NJDEP SGSL in four soil gas samples but not detected in any indoor air samples, indicating that the VI pathway is not complete for chloroform. Benzene was the only other compound detected at a concentration greater than the NJDEP SGSL, but the concentrations in indoor air were all below the NJDEP IASL and indoor air concentrations were similar to the ambient air concentrations, which indicates that the VI pathway is not complete for benzene.

As part of this BHHRA Second Interim Deliverable, the On-Site Vapor Intrusion Investigation results have been evaluated using the USEPA Vapor Intrusion Screening Criteria Levels (VISL) presented in the VISL Calculator (USEPA, 2013a) for a commercial scenario and the USEPA Region 2 VI Matrix approach to determine the need for further investigation or action. On-Site soil gas and indoor air results were compared to the USEPA SGSLs and USEPA IASLs for a commercial scenario (obtained from the VISL Calculator); this comparison is presented in **Table 1-1**. The following is a summary of the results of the comparison:

- VOCs were detected in one or more of the sub-slab soil gas and indoor air samples collected from the currently unoccupied building at the CPS property.
- Only four VOCs, benzene, chloroform, ethylbenzene, and tetrachloroethylene, were detected in one or more sub-slab vapor samples at concentrations greater than the USEPA SGSLs for a commercial scenario.

- No VOCs were detected in indoor air samples at concentrations greater than the USEPA IASL for a commercial scenario.

The USEPA Region 2 VI Matrix approach requires the evaluation of laboratory analytical data from co-located soil gas and indoor air sampling locations to make recommendations about further action on an analyte-specific and location-specific basis. For carcinogens, these recommendations range from (1) No Action to (9) Pursue Remediation, depending on the concentrations of volatiles detected in soil gas and indoor air with respect to the USEPA SGSLs and USEPA IASLs. For the purposes of this evaluation, the USEPA SGSLs and USEPA IASLs for a commercial scenario (obtained from the USEPA VISL Calculator) were used in the USEPA Region 2 VI Matrix approach. The findings of the USEPA Region 2 VI Matrix evaluation indicate that the indoor air and soil gas concentrations of benzene, ethylbenzene, chloroform, and PCE do not require immediate action. Instead, monitoring is the suggested approach for chloroform. Refer to **Attachment D-4** for a copy of the USEPA Region 2 VI Matrices for benzene, ethylbenzene, chloroform, and PCE. Below is a brief summary of the findings.

Benzene was detected in sub-slab soil gas sampling locations SG-01, SG-02, and SG-03 at concentrations ranging from 19.2 µg/m^3 to 93.9 µg/m^3, all of which are greater than the USEPA SGSL of 16 µg/m^3, but less than ten times the USEPA SGSL of 160 µg/m^3. The co-located indoor air concentrations ranged from 0.93 µg/m^3 to 1.15 µg/m^3, all of which fall below the USEPA IASL of 1.6 µg/m^3. According to the USEPA VI Matrix (presented in **Attachment D-4)**, the recommendation is No Action for sub-slab soil gas sampling locations SG-01, SG-02, and SG-03, as benzene was detected at a concentration greater than the USEPA SGSL, but below the USEPA IASL at each of these locations.

Ethylbenzene was detected in sub-slab soil gas sampling locations SG-01, SG-02, and SG-04 at concentrations ranging from 64.7 µg/m^3 to 221.1 µg/m^3, all of which are greater than the USEPA SGSL of 49 µg/m^3, but less than ten times the USEPA SGSL of 490 µg/m^3. The co-located indoor air concentrations range from 0.65 J µg/m^3 to 0.96 µg/m^3, all of which fall below the USEPA IASL of 4.9 µg/m^3. According to the USEPA VI Matrix (presented in **Attachment D-4)**, the recommendation is No Action for sub-slab soil gas sampling locations SG-01, SG-02, and SG-04, as ethylbenzene was detected at a concentration greater than the USEPA SGSL, but below the USEPA IASL at each of these locations.

PCE was detected in sub-slab soil gas sampling location SG-01 at 936 µg/m^3 which is greater than the USEPA SGSL of 470 µg/m^3, but less than ten times the USEPA SGSL of 4700 µg/m^3. In the co-located indoor air sample, PCE was not detected above the method detection limit of 0.14 µg/m^3. According to the USEPA VI Matrix (presented in **Attachment D-4)**, the recommendation is No Action for sub-slab soil gas sampling locations SG-01, as PCE was detected at a concentration greater than the USEPA SGSL, but below the USEPA IASL at this location.

Chloroform was detected in sub-slab soil gas sampling locations SG-01, SG-02, SG-03, and SG-04 at concentrations exceeding the USEPA SGSL of 5.3 µg/m^3. The chloroform soil gas concentrations at locations SG-01 (29.8 µg/m^3) and SG-03 (33.7 µg/m^3) are greater than the USEPA SGSL of 5.3 µg/m^3, but less than ten times the USEPA SGSL of 53 µg/m^3. The chloroform soil gas concentrations at locations SG-02 (202.2 µg/m^3) and SG-04 (209 µg/m^3) are greater than both the USEPA SGSL of 5.3 µg/m^3 and ten times the USEPA SGSL of 53 µg/m^3, but less than

100 times the USEPA SGSL of 530 µg/m^3. The co-located indoor air concentrations were non-detect at each of these sample locations at 0.14 U µg/m^3. According to the USEPA VI Matrix (presented in **Attachment D-4)**, the recommendation is Option (4) Monitor for sub-slab soil gas sampling locations SG-01 and SG-03, as chloroform was detected at a concentration greater than the USEPA SGSL, but not detected in the co-located indoor air samples at each of these locations and Option (7) Monitor for sampling locations SG-02 and SG-04 as chloroform was detected at concentrations greater than the SGSL, but not detected in the co-located indoor air samples.

2009 Vapor Intrusion Investigation Madison Property and Subsequent Updates

VI investigations were conducted on the Madison property as described in the Off-Site Vapor Intrusion Investigation Reports included in Appendix E of the 2013 RI Report (MACTEC, 2009b). The Madison property ("Off-Site") Vapor Intrusion Work Plan was approved on August 20, 2009. The investigation involved the comparison of groundwater data to NJDEP vapor intrusion-based GWSLs, collection of soil vapor samples, and comparison of the soil vapor results to NJDEP SGSLs.

The Off-Site VI investigation (MACTEC, 2009b) called for a phased approach, including soil vapor sampling and analysis in the Copper Building with additional investigation of Copper building indoor air and soil gas and indoor air sampling at two other buildings, Maintenance and Zinc/Brass, implemented as necessary. The initial sampling included sub-slab sampling (Summa canisters) within the laboratory and break room portions of the Copper Building (occupied, slab-on-grade structure) at the Madison Site. The Copper Building was investigated because it is located immediately downgradient of the CPS source area and groundwater concentrations of VOCs were above NJDEP GWSLS in monitoring wells upgradient of that building. Two other buildings, Maintenance and Zinc/Brass, were not investigated initially as the Maintenance Building is located further downgradient of the CPS source area, and the Zinc/Brass Building is located side-gradient and across Prickett's Brook.

Sub-slab sampling was conducted from 6" double screened stainless steel vapor sampling implants, packed in sand, sealed with bentonite, and fitted with 3" aluminum flush mounts that were set in place with concrete. The implants were leak tested using helium prior to sampling. Samples were analyzed for VOCs using method TO-15.

During the initial off-site vapor intrusion investigation, sub-slab soil vapor data were compared to the NJDEP SGSLs to determine the need for further investigation or action in accordance with NJDEP VI Guidance and Decision Matrix Flow Chart. Only chloroform was detected in soil gas samples above SGSLs in both samples and the duplicate. Chloroform was not identified above the GWSL in any of the groundwater samples, indicating that the presence of this compound is not associated with the groundwater plume. Concentrations of all other detected compounds in soil gas samples were below corresponding non-residential SGSLs. A copy of this VI evaluation is included in **Attachment D-2**.

Consistent with the NJDEP VI Guidance, multiple lines of evidence were evaluated to determine appropriate action for the VI pathway. Based on the VI investigation findings and review of data with respect to NJDEP screening levels and VI Guidance/Decision Flow Chart, there was no immediate adverse health risk or rapid response action required at the time. Based on the low

relative exceedance of the screening level for chloroform, the lack of correlation of soil gas and groundwater sample results, and potential contribution from other sources no further evaluation of the VI Pathway was recommended in the Copper Building or downgradient and side-gradient of the Copper Building.

As part of the BHHRA First Interim Deliverable, Table 3 of the Off-Site VI Investigation Report was updated to include the NJDEP March 2013 SGSLs. This table was presented as Table 4 in the BHHRA First Interim Deliverable and is included in **Attachment D-3**. The results presented in the updated table are consistent with the original Off-Site VI Investigation Report. Only chloroform was detected in soil gas samples above NJDEP 2013 SGSLs in both samples and the duplicate. This confirms the previous conclusion that no further evaluation of the VI Pathway is recommended in the Copper Building or downgradient/side-gradient of the Copper Building.

As part of this BHHRA Second Interim Deliverable, the Off-Site Vapor Intrusion Investigation results were evaluated using the USEPA VISL presented in the VISL Calculator (USEPA, 2013a) for a commercial scenario and the USEPA Matrix approach to determine the need for further investigation or action. On-Site soil gas results were compared to the USEPA SGSLs for a commercial scenario (obtained from the VISL Calculator); this comparison is presented in **Table 1-2**. The following is a summary of the results of the comparison:

- VOCs were detected in off-site soil gas samples;
- Benzene, chloroform, and ethylbenzene were detected in one or more samples at concentrations greater than the corresponding USEPA SGSLs.
- No co-located indoor air samples were collected as part of the approved Off-Site VI investigation Work Plan (2009).

The USEPA Region 2 VI Matrix approach requires the evaluation of laboratory analytical data from co-located soil gas and indoor air sampling locations to make recommendations about further action on an analyte-specific and location-specific basis. These recommendations range from (1) No Action to (9) Pursue Remediation, depending on the concentrations of volatiles detected in soil gas and indoor air with respect to the USEPA SGSLs and IASLs. For the purposes of this evaluation, the USEPA SGSLs for a commercial scenario (obtained from the USEPA VISL Calculator) were used in the matrix approach. The matrix approach indicates that if a constituent is detected at a concentration greater than the USEPA SGSLs, then indoor air sampling is recommended. Therefore, due to the concentrations of benzene, chloroform, and ethylbenzene detected at concentrations greater than the USEPA SGSLs, indoor air sampling would be recommended as the next step.

<u>Screening of Shallow Groundwater Data Using NJDEP Criteria and 2013 USEPA GWSLs</u>

In the BHHRA First Interim Deliverable, Area 1 shallow groundwater data (location of the CPS source area) were summarized and compared to the NJDEP 2013 VI GWSLs. This comparison was presented in Table 6 of the BHHRA First Interim Deliverable and is included in **Attachment D**. **Figure 1-8** presents the location of the shallow groundwater sampling locations within Area 1. Maximum concentrations of the following compounds were greater than the NJDEP 2013 VI GWSLs: 1,1,2,2-tetrachloroethane, 1,2,4-trichlorobenzene, 1,2-dichloroethane, 1,4-

dichlorobenzene, benzene, chlorobenzene, trichloroethene, and vinyl chloride. As part of the BHHRA Second Interim Deliverable, Area 1 shallow groundwater data were also summarized and compared to the USEPA VISL GWSLs. **Table 1-3** presents this comparison. Maximum concentrations of the following compounds are greater than the USEPA VISL GWSLs: 1,2,4-trichlorobenzene, 1,2-dichloroethane, 1,4-dichlorobenzene, benzene, chlorobenzene, ethylbenzene, naphthalene, and vinyl chloride. Currently, there are no buildings present within Area 1; however, a comparison of the groundwater analytical data from Area 1 with both the NJDEP VI GWSLs and the USEPA VISL GWSLs indicates that there is a potential for a vapor intrusion pathway if buildings were built and occupied in the future.

The BHHRA First Interim Deliverable included a comparison of the analytical data for shallow groundwater samples in Area 2 of the former CPS Facility property with the NJDEP 2013 VI GWSLs. This comparison was presented in Table 3 of the BHHRA First Interim Deliverable and is included in **Attachment D**. Area 2 groundwater includes several sampling locations around the perimeter, as well as upgradient of the only potentially occupied building on the former CPS Facility property. **Figure 1-8** identifies the groundwater sample locations associated with the analytical data that were included in this evaluation. Ten VOCs have been detected in at least one of the shallow groundwater samples located within Area 2, however, all detected concentrations were very low (1 µg/L or less) and all detected concentrations were below corresponding NJDEP 2013 VI GWSLs. For this BHHRA Second Interim Deliverable, Area 2 shallow groundwater concentrations were compared to USEPA VISL GWSLs. All detected groundwater concentrations were also below USEPA VISL GWSLs as well. Refer to **Table 1-4** for this comparison. This evaluation indicates that using both NJDEP and USEPA screening criteria vapor intrusion associated with potential groundwater impacts in Area 2 is not of concern and requires no further evaluation.

The BHHRA First Interim Deliverable included a comparison of the analytical data for shallow groundwater samples in Area 3 (the side lot) of the former CPS Facility property with the NJDEP 2013 VI GWSLs. Area 3 is upgradient and side-gradient of the CPS Site source area (Area 1), so substantial VOC detections in shallow groundwater were not expected. Only three compounds were detected in the three samples (acetone, carbon disulfide, and MTBE). All concentrations were orders of magnitude below the NJDEP 2013 VI GWSLs. This comparison was presented in Table 5 of the BHHRA First Interim Deliverable and is included in **Attachment D-3**. As part of the BHHRA Second Interim Deliverable, the Area 3 shallow groundwater data has been compared to the USEPA VISL GWSLs. This comparison is presented as **Table 1-5**. The three detected concentrations are orders of magnitude below the USEPA VISL GWSLs as well. This evaluation indicates that using both NJDEP and USEPA screening criteria vapor intrusion associated with potential groundwater impacts in Area 3 is not of concern and requires no further evaluation.

<u>Weight of Evidence Evaluation and Conclusions</u>

On-Site

Groundwater analytical results were used to evaluate the VI pathway at Area 1 as there are no existing buildings in this area, and sub-slab soil gas and indoor air results are not available.

A comparison of the groundwater analytical data from Area 1 with both the NJDEP and USEPA VI GWSLs demonstrated that several compounds are greater than either NJDEP and/or USEPA VI GWSLs. Therefore, there is a potential for a vapor intrusion pathway in Area 1 if buildings were built and occupied in the future.

Groundwater analytical results and co-located sub-slab soil gas results and indoor air results were used to evaluate the VI pathway in Area 2. A comparison of shallow groundwater analytical results with NJDEP VI GWSLs, sub-slab soil gas with NJDEP SGSLs, and co-located indoor air samples with NJDEP IASLs using updated NJDEP 2013 guidance indicated that although individual compounds were detected at concentrations greater than individual screening criteria, no compounds were consistently detected above both NJDEP SGSLs and NJDEP IASLs. Additionally, no analytes were detected in shallow groundwater at concentrations greater than the NJDEP VI GWSLs. A comparison of shallow groundwater with USEPA VISL GWSLs, sub-slab soil gas with USEPA SGSLs, and co-located indoor air samples with USEPA IASLs indicated similar results. VOCs have been detected above USEPA SGSLs, but not above USEPA VISL GWSLs or USEPA IASLs. Although the USEPA Region 2 VI Matrix approach recommends that the vapor intrusion pathway should be monitored for chloroform, multiple lines of evidence indicate that the vapor intrusion pathways is not complete. Concentrations of chloroform have either been non-detect and/or detected at very low concentrations in groundwater in the vicinity of the unoccupied office, laboratory, and warehouse portions of the existing building at the CPS Site, which indicates that it is unlikely that groundwater represents a continuing source of the sub-slab soil gas concentrations detected above the USEPA SGSL. Additionally, indoor air concentrations are consistent with background sampling locations, indicating that concentrations of volatile constituents in sub-slab soil gas are not migrating to indoor air, and instead the indoor air concentrations are representative of background concentrations in the area. This conclusion is consistent with the findings of the vapor intrusion evaluation that has been performed with respect to the NJDEP 2013 Vapor Intrusion Guidance described above.

In the Off-Site VI Report (REF), results of the June 2007 round of sampling at 26 monitoring wells (CPS-3A, WCC-1M, WE-2RB, WCC-3M, CPS-1, WCC-12, MI-7, DW-53, DW-5D, DW-10D, EPA-5, DW-9D, DW-9S, EPA-2, EPA-1, DW-14, DW-13D, RW-2, DW-1D, DW-1S, WCC-16VS, DEP-2, PA-B, MI-8, RS-2B, and RS-2C) were presented. Of these monitoring well locations, wells up-gradient or in the immediate vicinity of the off-site soil gas sampling locations are CPS-3A, WE-2RB, and CPS-1. When the most recent analytical results for these monitoring wells are evaluated with respect to the most recent USEPA VI GWSLs, of the three analytes detected in soil gas samples with concentrations above the SGSLs, benzene was the only analyte detected at concentrations above USEPA GWSLs. It was detected in samples from all three of these groundwater sample locations. Given concentrations of benzene in groundwater and in soil gas, the potential for a vapor intrusion pathway cannot be eliminated. However, because detected concentrations of benzene just slightly exceed the USEPA SGSL; it is unlikely that concentrations of benzene in soil gas are sufficient to migrate to indoor air at concentrations that may pose a risk to human health.

1.5.3 Migration Pathways

The 2013 RI Report (BASF, 2013) includes a comprehensive presentation and discussion of the physical CSM. Section 4.1 of that report (Physical Characteristics of the Site and Surrounding

Areas) provides descriptions of soils, groundwater characteristics, flow regimes, and downgradient uses (public water supply), the surface water bodies (Prickett's Brook, Prickett's Pond, and Tennent's Pond), and groundwater/surface water interaction. Section 4.3 of the RI report summarizes nature and extent of contamination for soil, groundwater, soil gas and indoor air, and surface water and sediment, while Section 5.0 summarizes the CSM. This information is not repeated here.

Section 4.3 of the RI report concluded that the CPS plume (VOCs) and Madison plume (metals) are well defined and that "the CPS and Madison Site IRM recovery wells appear to be limiting offsite migration of CPS groundwater COIs". There are limited residual impacts to groundwater in the Runyon Wellfield Watershed, and because migration from the CPS source area is being limited, migration of CPS COIs to the wellfield is not sufficient to have an adverse impact on water supply water quality. The RI Report cites a study by Wehran Engineering that "found no evidence of sediment impact attributable to runoff from the CPS Site only several years after the pavement and curbing were installed, suggesting that any earlier sediment migration from the CPS Site via runoff was either negligible or non-existent". The migration of volatiles from the subsurface (i.e., soil gas) was evaluated for the former CPS Facility property and the Madison property in 2009 and the results were re-evaluated in this document (Section 1.5.2.4 above). Those evaluations concluded that vapor intrusion is not a significant concern for existing buildings (Area 2), that vapor intrusion potential is not a significant concern for the CPS side lot (Area 3), and there is vapor intrusion potential for hypothetical future buildings (in the absence of engineering controls) in Area 1 (source area) of the former CPS Facility property. The Tier I groundwater/surface water interaction study (Section 3.2.3 of BASF [2013]) "did not identify any groundwater recharge areas where VOCs or SVOCs exceeded GWQS in sub-streambed groundwater" and further concluded "surface water and sediment are neither sources nor sinks for CPS Site-related constituents".

1.5.4 Current and Foreseeable Site Conditions

Section 4.1.1 of the 2013 RI Report identifies, for the human health risk assessment, current and foreseeable site conditions, potential human receptors, potential exposure media, and routes of exposure for each hypothetical receptor. Because the text in Section 4.4.1.1 of that report provides information required for this HHRA, it has been reproduced below.

As indicated on **Figure 1-3**, the site consists of the former CPS property parcel, which contained the plant production areas, and a side lot, which is largely undeveloped. The CPS Site is further subdivided into three sub areas (Area 1, Area 2, and Area 3), which represent the Former Production area, the Former Plant area and the Side Lot area, respectively.

In December 2001, the CPS Chemical plant ceased commercial operation and by November 2005 the structures associated with the plant operations were demolished, except for the laboratory/office/warehouse building, the loading dock, a small utility building and the groundwater treatment plant building. Except for the former tank farm area, which was demolished and is currently an unpaved water filled depression, the other areas with soil cement and paving remained intact, although some asphalt surfaces were damaged during demolition.

The former CPS Plant Area (Area 2) is about 95% paved with asphalt or concrete, while the CPS Side Lot (Area 3) area is 100% unpaved. Note that the groundwater recharge basin supporting the IRM is sited in Area 3.

The only current use of the CPS property is operation and maintenance of a groundwater extraction and treatment system.

There are no definitive foreseeable plans for the former CPS Site; however, if possible, BASF would like to put into productive use both Areas 2 and 3. Areas 2 and 3 generally contain lower levels of contamination than does Area 1 (the former tank farm). Future use(s) of these areas would likely be industrial, which is the current zoning status.

Properties south and east of the CPS Site are undeveloped, while the Madison Industries Facility is located immediately west of the CPS Site and industrial properties are located to the north. The closest major residential area is over one-half mile to the northeast of the site in a suburban setting; nearest residences are approximately 1,000 feet north of the site. A municipal sewer line (easement) bisects the CPS property from northeast to southwest. The Perth Amboy municipal water supply Runyon Supply Wells are located approximately 3,000 ft. southwest of CPS.

The exposure scenarios, including identified potential receptors, exposure media and routes of exposure, are described below and summarized in **Table 1-6**. **Table 1-6** also lists the data sets intended to be used to evaluate each route exposure scenario.

1.5.5 Potential Human Receptors

The 30-acre property as well as most of the surrounding area is zoned SD3, Specialized Development for industrial land use as part of the Township's long term development plan, and therefore it is unlikely that these areas will be used in the future for residential development. The former CPS Site was previously used for industrial purposes and although it is currently unused, it is likely that future use would be industrial. Future indoor industrial workers and outdoor commercial workers are potential future on-Site receptors. In addition, although a trespasser scenario is unlikely since the site is located in an industrial area and the closest major residential area is present at approximately ½ mile, we have conservatively assumed a nearby resident could trespass the Site. A construction worker scenario is also considered, as Site redevelopment is likely. Potential down gradient receptors include consumers of drinking water from the Runyon Well Field and visitors to Pricketts Brook and Pricketts Pond. The pond and brook are not used for recreational purposes and are not used directly for drinking water.

The portion of Pricketts Brook that is on the CPS and Madison Industries properties is on privately owned, fenced industrial property and is not accessible to the public. Recreational activity is not expected as public access is not allowed. Additionally, the brook is shallow, narrow, and intermittent, all of which would make Pricketts Brook an unlikely location for recreational use. A photograph log has been included as **Attachment E**, to further illustrate the conditions in Pricketts Brook and Pricketts Pond. Photographs 1 and 2 depict the condition of Pricketts Brook as it passes through the CPS property and Photographs 3 through 7 depict the condition of Pricketts Brook as it passes through the Madison Property. It should be noted that at the time of the site visit (October 2012), the brook ran dry at multiple locations on the Madison Property.

As Pricketts Brook leaves Madison Industries and travels towards Pricketts Pond, the brook is narrow (less than 10 feet wide) and shallow typically less than 1 foot deep. Additionally, Pricketts Brook is located in a heavily vegetated and/or heavily wooded area with limited access. Given the limited access and shallow nature of the brook, it is unlikely it would be used for recreational activities. Photographs 8 through 10 depict Pricketts Brook as it passes from the Madison property towards Pricketts Pond.

Pricketts Pond is located on property owned by Perth Amboy, and it is a recharge pond associated with the public water supply systems' Runyon Wellfield. The Runyon Watershed is fenced and has signs on the perimeter indicating the area is a watershed. While trespassing within the watershed is possible, it appears to be uncommon. If trespassers were to visit the Pond, incidental contact with surface water/sediment at the shore is theoretically possible. Although recreational use (boating, swimming) of Prickett's Pond is hypothetically possible, it is not known to be used for recreational purposes, and since it is a recharge pond for the public water supply, recreational use is not an expected future use. Prickett's Pond is remote from any residences or populated areas, and is not easily accessible. The water feature observed during the site visit would not support activities such as boating, fishing, swimming, or wading.

Photograph 11 through 15 depict conditions in Pricketts Pond. As is visible in the photographs, the heavily vegetated/wooded perimeter limit access to the pond, and conditions in the pond including algae and vegetation do not make the pond an attractive recreational feature.

The Runyon Well Field is used as a potable water supply. No receptors have been identified for Tennent Pond because it is located down gradient of the Well Field and has not been impacted by site-related contaminants.

Although there is no current or foreseeable future potable or non-potable use of groundwater at the CPS Property, we have conservatively planned to assess a drinking water scenario (ingestion, dermal contact, and inhalation of volatiles) for on-Site groundwater (see **Table 1-6**). There is a CEA in place at the CPS property that obviates the use of the groundwater as a drinking water source for as long as the CEA remains in place. The drinking water scenario is evaluated because site groundwater is within the zone of contribution of the Runyon wellfield, and because it will assist in guiding further cleanup decisions (remedial goals). As indicated in **Table 1-6**, the hypothetical future potable use of on-Site groundwater has been included as part of the exposure scenario for each of the on-Site receptors (except the trespasser and construction worker). This is an unlikely scenario, but has been included for completeness.

In summary, the following potential receptors were identified under current use:

- Trespasser (adolescent).

The current workers at the site can be considered remedial workers, and they are not typically evaluated in a baseline human health risk assessment. Their work is regulated under OSHA.

The following potential receptors were identified under foreseeable future use:

- Trespasser (adolescent),

- Outdoor Commercial/Industrial worker (adult),
- Indoor Commercial/Industrial worker (adult),
- Construction Worker (adult),
- Utility Worker (working on sewer line); and
- Hypothetical Resident (child and adult).

The human receptors that will be evaluated and the associated exposure assumptions are documented in **Tables 3-13** through **3-15** of this document **(**based on **RAGS Part D Table 4s)**.

1.5.6 Potential Exposure Media

Soils - Contaminants have been detected in shallow zone soils of the former CPS Site. Higher levels have historically been detected in the main processing area (Area 1) and low levels have been detected in the side lot (Area 3). Currently, the potential for direct contact with contaminated soils is limited since the impacted soils are generally beneath the site cover associated with Areas 1 and 2 (reinforced concrete pads, soil cement and asphalt). However, it is possible the cover will be removed and/or redevelopment will occur in the near future, and therefore, we plan to evaluate potential exposures to site soils (incidental ingestion and dermal contact as well as inhalation of soil-derived dust for outdoor workers and construction workers). Consistent with the USEPA's Regional Screening Level (RSL) tables, the soil to ambient air pathway (both via volatilization and via particulates) typically contributes minimally to overall risk (a "de minimus" pathway), compared to the contribution from the direct contact exposure pathways (incidental ingestion, dermal contact). Therefore, the soil to ambient air transport pathway (volatilization) will not be evaluated in this assessment.

Groundwater - Groundwater is not currently used on-Site for potable or other purposes. The on-going pump and treat system is the only current activity related to groundwater. Although there is no current or foreseeable future potable or non-potable use of groundwater at the CPS Property, we have conservatively planned to assess a drinking water scenario (ingestion, dermal contact, and inhalation of volatiles) for groundwater within the CPS Plume. The evaluation of the potable use scenario will utilize representative groundwater data within the footprint of the plume. The RI characterized the CPS/Madison plume and it is fully delineated by the existing well network both in terms of concentration magnitude and extent. Therefore for the purposes of this BHHRA it is appropriate to use the existing monitoring well database to define groundwater impact.

Future construction activities could require intrusive activities down to a depth of 10 ft below ground surface (bgs). During that work, construction workers may be exposed to groundwater via incidental ingestion, dermal contact, and inhalation of volatiles in groundwater.

Ambient Air Volatile Emissions - Volatile constituents that are present in soil and/or groundwater can be released to ambient air through volatilization. This medium, typically evaluated via use of fate and transport models applied to a soil and/or groundwater source concentration, will be evaluated for a construction worker and resident. Potential exposure to volatiles released from an excavation in a construction scenario is the most likely exposure scenario for the construction

worker receptor. Residential exposure to volatile emissions in ambient air would occur during showering situations.

Vapor Intrusion - Indoor Air is a separate exposure medium, as listed in **Table 1-6**, under Potential Future Use. The evaluation of the vapor intrusion pathway is discussed in Section 1.5.2.4 above. The findings indicate that the vapor intrusion pathway is unlikely occurring on-Site and there is insufficient data to determine if it is occurring off-Site (although even if the pathways exists, it is unlikely to result in actionable risks). As a conservative measure, we will evaluate the vapor intrusion pathway in this HHRA to document the potential risks associated with this exposure pathway.

Air Particulate Emissions - Constituents containing soil particulates could be transported to ambient air from wind erosion or construction activities. The majority of Areas 1 and 2 are covered by pavement rendering this pathway unlikely, for current scenario. This pathway is more likely during a future construction event or during future outdoor work, where particulates could be released to ambient air during excavation and digging.

Sediment and Surface Water - The on-site portion of Pricketts Brook is dry most of the year, such that exposure is unlikely and therefore on-site surface water and sediment within the brook will not be evaluated. The sediments and surface waters of Pricketts Pond and Pricketts Brook directly downgradient of the CPS Site are discharge areas for groundwater. Remedial investigation evaluations have shown that CPS-impacted groundwater discharging to surface water would not likely produce adverse impacts to human or aquatic receptors in the receiving water bodies (Refer to **Attachment C** for a copy of the groundwater / surface water interaction study). This BHHRA references the groundwater/surface water interaction study as the means of evaluating the potential risks associated with exposure to surface water in Pricketts Brook and Pricketts Pond. COI from the CPS Site are limited to VOCs, which would not be anticipated to accumulate in sediment. Therefore risks associated with exposure to sediment will not be evaluated.

1.5.7 Routes of Exposure per Identified Potential Receptor

An exposure pathway is the course a chemical takes from its source to the person being contacted. Exposure pathway analysis links the sources, locations, and types of environmental releases with population locations and activity patterns to determine the significant pathways of human exposure. Exposure pathways generally consist of four elements: (1) a source and mechanism of chemical release, (2) a retention or transport medium, (3) a point of potential human contact with the contaminated medium (known as the exposure point), and (4) an exposure route at the contact point (e.g., ingestion of soil, inhalation of vapors) (USEPA, 1989). For the exposure pathway to be considered potentially complete, all four elements must be present.

An exposure point (also called an exposure area or exposure unit) is a location within which an exposed receptor may reasonably be assumed to move at random and where contact with an environmental medium (e.g., soil) is equally likely at all sub-locations. In addition to the behavior of receptors, the existing pattern of chemical constituents in environmental media is also considered in identifying exposure areas. The identified current and future receptors, the assumption of random exposure within an exposure area, and the nature and extent of contamination have been considered in identifying exposure areas for the BHHRA. Important

factors in identifying the exposure areas at the Property include the current and anticipated future uses of the various areas of the Site. Therefore, the BHHRA exposure areas at the Site reflect current and future receptors and the current and future uses of the various areas within the Site.

Environmental media evaluated quantitatively for in this BHHRA (exposure media) include surface soil (and airborne dust), subsurface soil (and airborne dust), groundwater within the CPS Plume, shallow groundwater on the CPS property, groundwater discharging to surface water (screening evaluation only) and indoor air.

Exposure routes are the mechanisms by which people are exposed to environmental media. Exposure routes that are typically evaluated in environmental risk assessments include ingestion of the environmental medium, skin (dermal) contact with the environmental medium, and inhalation of outdoor or indoor air. In this BHHRA, incidental ingestion and dermal contact with soil is evaluated for all receptors and potential inhalation of soil-derived dust is evaluated for outdoor workers and construction workers only. Ingestion, dermal contact, and inhalation of volatiles associated with the use of groundwater as a potable water supply will be evaluated for a future indoor commercial/industrial worker, outdoor commercial/industrial worker, and resident. Ingestion, dermal contact, and inhalation of volatiles from shallow on-Site groundwater will be evaluated for a construction worker and utility worker. Inhalation of vapors potentially released during soil excavation activities into outdoor air for construction/excavation workers will be evaluated using a box model approach.

Groundwater discharging to surface water will be screened for COPCs and discussed qualitatively in the BHHRA with respect to potential surface water impacts. Surface water and sediment data will not be evaluated in the BHHRA. Those media will be evaluated in the risk assessments conducted for the Madison Site.

A summary of the receptors and exposure scenarios evaluated in the BHHRA is provided in **Table 1-6** and presented below.

<u>Trespasser</u> – Adolescent trespassers (assumed to be nearby residents) are not anticipated to come into contact with on-site groundwater, as there is currently no access to groundwater by trespassers, there is no current use of on-Site groundwater, and volatilization of VOCs from groundwater through subsurface soils to overlying ambient air is anticipated to be small or not a complete pathway.

Although Areas 1 and 2 are mostly covered with pavement, there are some areas of exposed soils where adolescent trespassers may come into contact with surface soil. Therefore, exposure to surface soil via incidental ingestion and dermal contact is conservatively assumed for a current trespasser.

Currently there is no access to subsurface soil for trespassers, however, if the site is redeveloped in the future, subsurface soil could be brought to the surface. Therefore, potential exposure to subsurface soil exposure may be a complete pathway in the future and includes incidental ingestion and dermal contact. Inhalation of particulates and volatiles from subsurface soils to overlying ambient air is anticipated to be minimal or not a complete pathway, and is not evaluated.

Exposure to surface water and sediment in the on-site portion of Pricketts Brook is not considered a complete pathway via incidental ingestion or dermal contact because this portion of the brook is dry most of the year.

Exposure to surface water and sediment in the off-site portion of Pricketts Brook is not considered because the Groundwater/Surface Water Interaction Evaluation (discussed in Section 3.2.3 of the RI (BASF, 2013) concluded that these media are not of concern. The RI (BASF, 2013) concluded that groundwater to surface water migration is the only possible exposure pathway and that groundwater concentrations were below relevant human health risk surface water screening values) and this exposure pathway is considered incomplete.

Future Outdoor Commercial/Industrial Worker - An outdoor commercial/industrial worker is not expected to be exposed to surface soil via incidental ingestion, dermal contact, or inhalation of particulates or volatiles under current conditions, as the site is not currently in use. However, it is possible the site will be used in the future and that pavement and structures could be removed. Therefore, it is assumed that a future outdoor commercial/industrial worker may come into contact with surface soil via incidental ingestion, dermal contact, and inhalation of particulates.

Currently there is no exposure to subsurface soil for an outdoor commercial/industrial worker because the site is not in use. Even if the site were currently in use, an outdoor worker's activities would be limited to the ground surface precluding subsurface exposure. However, if the site is redeveloped in the future, subsurface soil could be brought to the surface and potential future exposure pathways would include incidental ingestion, dermal contact, and inhalation of particulates. Inhalation of volatiles from subsurface soils to overlying ambient air is anticipated to be small or not a complete pathway, and is not evaluated.

There is currently no use of groundwater at the Site. An on-Site groundwater potable use scenario will be evaluated for the future outdoor commercial/industrial worker.

Future Indoor Commercial/Industrial Worker - An indoor commercial/industrial worker is not expected to be exposed to surface or subsurface soil as the indoor worker is assumed to spend all day indoors; however because USEPA guidance for the indoor worker assumes some contact with soil, we plan to evaluate potential soil exposures via incidental ingestion, dermal contact, and inhalation of particulates as a foreseeable future use scenario assuming the site is redeveloped and indoor workers are present.

Inhalation of volatiles in indoor air is not considered a substantial complete exposure pathway for current or future indoor commercial/industrial workers as the vapor intrusion investigations/evaluations conducted both on-site and off-site indicated that the subsurface to indoor air pathway is not complete. However, the vapor intrusion evaluations focused on existing buildings. It is recognized that subsurface conditions differ and that it is possible a future building could be constructed elsewhere on the property. An on-Site groundwater potable use scenario will be evaluated for the future indoor commercial/industrial worker.

Future Construction Worker - It is assumed that an adult construction worker may come into contact with both surface and subsurface soil at Areas 1, 2, and 3 (each exposure point will be evaluated separately) via incidental ingestion, dermal contact, and inhalation of particulates if

excavation were to take place in the future. During an excavation a construction worker may also come into contact with shallow groundwater via incidental ingestion and dermal contact, as well as inhalation of volatiles.

Future Utility Worker - It is assumed that a utility worker may come into contact with both surface and subsurface soil in the vicinity of the sewer line that traverses the Site via incidental ingestion, dermal contact, and inhalation of. During work, a utility worker may also come into contact with shallow groundwater via incidental ingestion, dermal contact, and inhalation of volatiles.

Hypothetical Future Resident – For a hypothetical future residential use, potential exposure pathways to soil may include incidental ingestion and dermal contact. Although this scenario is not considered a realistic future use, it is evaluated for the purpose of determining the need for institutional controls and/or further remediation. An on-Site groundwater potable use scenario will be evaluated for the hypothetical future resident.

2.0 DATA EVALUATION AND IDENTIFICATION OF CHEMICALS OF POTENTIAL CONCERN

The data evaluation and selection of COPCs described in this section includes the following components:

- Summary of media and areas associated with the CPS facility that have been investigated and that are evaluated in the BHHRA;
- Identification of available analytical data relevant to the BHHRA;
- Identification of data representative and not representative of current and future conditions at the Site;
- Summary of data quality, with an emphasis on potential limitations that could introduce uncertainty into the risk assessment;
- Summarization of analytical data for each medium evaluated in the BHHRA;
- Methods used to group and summarize data for use in the risk assessment; and
- Selection of COPCs for each medium.

Section 2.1 is a summary of data collected and considered for use in this BHHRA. Section 2.2 is a general discussion of data evaluation methods. Section 2.3 documents the data evaluation and selection of COPCs. **Attachment A** identifies and documents the analytical data selected for use in the BHHRA.

2.1 Data Collection Summary

Analytical data considered (but not necessarily selected) for the BHHRA includes the following:

- Soil analytical data collected between January 1992 and September 2012. Soil data has been collected for VOCs, SVOCs, and metals.
- Groundwater analytical data collected between April 1987 and September 2012. Groundwater analytical data has been collected for VOCs, SVOCs, pesticides/polychlorinated biphenyls (PCBs), total metals, dissolved metals, inorganics, dissolved gases, and TPH. Most recent analytical results for groundwater have generally been selected for use in the risk assessment.
- Analytical groundwater data collected during the December 2010 groundwater / surface water interaction study (included as **Attachment C**). As this evaluation was used to evaluate potential risks associated with surface water, only those locations where it was concluded that groundwater is upwelling or discharging to surface water were considered in this BHHRA.
- On-site soil gas and indoor air samples collected in September 2009 collected as part of the on-site vapor intrusion investigation. Off-site soil gas samples collected in September 2009 as part of the off-site vapor intrusion investigation.

The entire body of available medium-specific analytical laboratory data for soil, groundwater, groundwater discharging to surface water, soil gas, and indoor air has been evaluated to determine the subsets of data that are appropriate to characterize human health risks for current and foreseeable future land uses. To facilitate this analysis, a comprehensive database was developed and maintained, and it is included as part of the Remedial Investigation Report.

2.2 General Data Evaluation Considerations

Overall, the data evaluation and selection of data for use in the BHHRA have been conducted to identify data that are: (1) representative of existing soils, groundwater, groundwater discharging to surface water, and indoor air conditions; and (2) "usable" (that is, of sufficient quality) for BHHRA purposes.

2.2.1 Representative Data

Data associated with soil samples inaccessible to human receptors (such as deep subsurface soils greater than 10 ft bgs) have been excluded from the BHHRA. Soil data that are considered "representative of current conditions" are those associated with samples that were collected from media that remain at the Site and there is no reason to believe that detected compounds and associated concentrations have changed substantially since the time of sample collection. Conditions in transient media, such as groundwater, may vary over time, and recent sample data may be more appropriate for evaluating risks rather than historical data.

Therefore, the analytical data for soil, groundwater, and soil gas were evaluated to identify the data that are representative of current and foreseeable conditions at the Site.

2.2.2 Usable Data for Human Health Risk Assessment Purposes

USEPA risk assessment guidance (USEPA, 1989) discusses usability of data for risk assessment purposes and identifies several factors to be evaluated when determining data usability, including:

- Accepted or approved analytical methods;
- Reporting limits sufficient to identify concentrations of potential concern;
- Data validation that addresses precision, accuracy, repeatability, completeness, and comparability (PARCCs criteria) of the laboratory analytical data.

The data sets to be used in the BHHRA have been identified based on their representative nature and usability as outlined above. The data have been summarized by media, and COPCs selected, as described in the following subsections.

2.3 Data Evaluation and Selection of COPCs

The available analytical data for soil, groundwater, groundwater discharging to surface water, and indoor air have been compiled and evaluated in a manner consistent with Sections 2.2.1 and 2.2.2 to select the data to be used in the BHHRA. Subsequently, COPCs have been selected for each

of the environmental media. The following subsections document the data evaluation and selection of COPCs for this BHHRA.

2.3.1 Data Evaluation and Representative Data

The data evaluation, which included data validation, for the Site data was performed as part of the RI process; refer to the RI (BASF, 2013) for a discussion of the data evaluation. All soil laboratory analytical data included in the database for the Site were considered representative of conditions at the Site with the exception of the following:

- Analytical data associated with deep subsurface soil samples (top depth greater than 10 ft bgs) have not been included in the dataset used for the BHHRA because those deep soils are not accessible for current or foreseeable receptors.
- A total of 67 of the 113 detected analytes in on-Site soils (Areas 1 through 3 from 0 to 10 ft bgs) have at a minimum one non-detect result where no reporting limit was listed in the database. A "0" was listed in reporting limit field in the database when this occurred. These "0"s were not included in the exposure point concentration (EPC) calculations in this BHHRA; The "0"s are simply placeholders and do not have any meaning with respect to the data. It should be noted that these "0"s were retained as 'not detected' in the COPC selection tables, so that the frequency of detection represents the actual number of samples that were analytes. However, it should be noted that the inclusion of these "0"s does not affect the COPC selection process as they represent non-detect values.
- Two soil samples had entries for both initial analyses and analyses on dilution. Typically, data validation qualifiers would "reject" one set of results, so that there is one set of results associated with the sample. It appears that this did not occur for two samples in the database (GP-2 and GP-3). Therefore, the results for reanalysis on dilution was used in the BHHRA for those analytes that exceeded the calibration standard in the initial analysis.
- QA/QC samples, including field duplicates, have not been included in the BHHRA dataset. The corresponding field samples are considered representative of site conditions. The QA/QC samples were used exclusively for data validation purposes.

With the exception of the bulleted items above, the analytical data presented in the RI Report and contained within the Site database were considered for inclusion in this BHHRA. For groundwater, the most recent analytical data have generally been selected for use in the risk assessment. The following Sections document which groups of samples were considered for COPC selection and EPC calculations. These decisions were made based on which data were considered representative of Site conditions and appropriate for use in the BHHRA.

2.3.2 Selection of Chemicals of Potential Concern

The risk assessment dataset derived through the data evaluation process described above was utilized to produce subsets of data to be used for selecting COPCs for the following media:

- Soils in Areas 1, 2, and 3 from 0 to 10 feet below ground surface (ft bgs) (**Tables 2-1 through 2-3**).

- The most recent groundwater results, by parameter, from monitoring well locations within the CPS Plume (**Table 2-4).**
- Groundwater analytical data obtained from the groundwater to surface water interaction study (included as **Attachment C**). Only those locations where it was concluded that groundwater is upwelling or discharging to surface water were considered in this BHHRA and only volatile constituents were considered. (**Table 2-5**)
- Analytical results from the one round of Indoor Air sampling performed in September of 2009 (**Table 2-6)**

Tables 2-1 through **2-6** are 'RAGS Part D Table 2's' that provide summaries of the risk assessment data for Site media and that also document the selection of COPCs. **Tables 2-1** through **2-6** utilize the following descriptors to summarize the data sets:

- Frequency of detection (number of positively detected results/total number of results)
- Range of reporting limits (SQLs) for non-detects
- Range of detected concentrations
- Data qualifier associated with each maximum detected concentration
- Sample location associated with each maximum detected concentration

The chemicals considered to be likely to pose more than a *de minimis* level of risk are identified through the COPC selection process, and subsequently included in the quantitative BHHRA. The COPCs are selected by reducing the number of chemicals to be considered by applying a concentration/toxicity screen and by eliminating essential nutrients. The procedure used to select COPCs for the HHRA is summarized as follows.

A. Concentration-Toxicity Screening

- Selected as a COPC in soil if the maximum detected concentration is greater than the USEPA RSL (adjusted) for residential soils (USEPA, 2013b).
- Selected as a COPC in groundwater if the maximum detected concentration is greater than the USEPA RSL (adjusted) for tap water (USEPA, 2013b).
- Selected as a COPC in groundwater discharging to surface water if the maximum detected concentration is greater than the USEPA RSL (adjusted) for tap water (USEPA, 2013b).
- Selected as a COPC in Indoor Air if the maximum detected concentration is greater than the USEPA RSL (adjusted) for residential indoor air (USEPA, 2013b).
- Chemicals for which no screening value is available are retained as COPCs unless they are essential nutrients.

The RSLs for soil address direct contact (ingestion and dermal contact) exposures, as well as inhalation of constituents that may be released to air. The published RSLs have been derived as the lower of the concentration associated with a cancer risk of 1 in 1 million ($1x10^{-6}$) and the concentration associated with a non-cancer hazard quotient (HQ) of 1. The published RSLs have

been adjusted for use in the risk-based screening step. The adjusted RSL used for that purpose is the lower of the concentration associated with a cancer risk $1x10^{-6}$ and the concentration associated with a non-cancer HQ of 0.1. The use of tap water RSLs to identify COPCs in groundwater discharging to surface water is a very conservative (health-protective) approach; the surface water in Pricketts Brook is not a drinking water resource and would not be expected to be a drinking water resource in the future.

B. Additional Considerations:

The following additional guidelines are used for COPC selection:

- A parameter is not selected as a COPC if it is considered an essential human nutrient. The following inorganic analytes are considered essential human nutrients: calcium, magnesium, potassium, and sodium. Several other constituents are also considered to be essential human nutrients (e.g., iron, selenium), but could also pose toxicity at elevated concentrations and were therefore were not eliminated from the list of COPCs based on essential nutrient status alone.

The results of the COPC selection for each data set are provided in **Tables 2-1** through **2-6**. The following notes are used in those tables to denote the reasons for selection or exclusion of analytes as COPCs:

ASL: Concentration used for COPC screening (maximum detected concentration) is greater than the risk-based screening value; the analyte is selected as a COPC.

BSL: The concentration used for COPC screening (the maximum detected concentration) is less than the risk-based screening value; the analyte is therefore not selected as a COPC.

FOD: The frequency of detection is below 5% and the maximum detected concentration is low: the analyte is therefore not selected as a COPC.

NSL: There is no risk-based screening value available; the analyte is selected as a COPC.

E: The analyte is an essential nutrient, and is therefore not selected as a COPC.

The results of the COPC selection are identified below, by medium, and are summarized in **Table 2-7.**

- COPCs in surface and subsurface soil in Areas 1, 2, and 3 include 1,1,2,2-tetrachloroethane, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2-cis-dichloroethylene, 1,2-dichlorobenzene, 1,2-dichloroethane, 1,3-dichlorobenzene, 1,4-dichlorobenzene, benzene, chlorobenzene, methyl-cyclohexane, ethylbenzene, methylene chloride, o-xylene, p-isopropyltoluene, tetrachloroethylene, toluene, trichloroethylene, total xylenes, 1,2,4-trichlorobenzene, 2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, biphenyl, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, naphthalene, aluminum, antimony,

arsenic, cobalt, copper, iron, manganese, mercury, thallium, and vanadium (**Tables 2-1 through 2-3**).

- COPCs in groundwater within the CPS Plume include 1,1,2,2-tetrachloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-cis-dichloroethylene, 1,2-dichlorobenzene, 1,2-dichloroethane, 1,2-dichloroethylene, 1,2-trans-dichloroethylene, 1,3,5-trimethylbenzene, 1,3-dichlorobenzene, 1,4-dichlorobenzene, 1-chlorobutane, 2-chlorotoluene, 3-methyl hexane, benzene, chlorobenzene, chloroform, methyl-cyclohexane, dimethylsulfide, ethylbenzene, m+p-xylene, methylene chloride, methyl-t-butyl ether, naphthalene, o-xylene, p-chlorotoluene, p-isopropyltoluene, sulfur dioxide, t-butyl alcohol, tetrachloroethylene, toluene, trichloroethylene, vinyl chloride, total xylenes, 1,4-dioxane, 2,4-dimethylphenol, 2-methylnaphthalene, 3-nitroaniline, aniline, biphenyl, bis(2-ethylhexyl)phthalate, aldrin, heptachlor epoxide, aluminum, arsenic, antimony,. barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, thallium, vanadium, and zinc. (**Table 2-4**). Although groundwater within the CPS Plume encompasses groundwater off of the CPS Property, a separate COPC screening was not performed for on-Site CPS Groundwater to be used in the construction worker evaluation. This COPC screening encompasses the source area, and thus provides a conservative list of COPCs to evaluate for all groundwater in this BHHRA.
- COPCs identified in groundwater discharging to surface water include 1,1,2,2-tetrachloroethane, 1,2,4-trichlorobenzene, 1,2-dichloroethane, 1,3-dichlorobenzene, 1,4-dichlorobenzene, benzene, methyl-t-butyl ether, t-butyl alcohol, trichloroethylene, and vinyl chloride. (**Table 2-5)**. It should be noted that further evaluation of this media will not be performed In this BHHRA. As described above, surface water exposure is not anticipated under current or future Site use. The findings of this COPC selection and a qualitative evaluation of potential exposure to surface water will be discussed in this risk assessment section of this BHHRA.
- Indoor Air: COPCs in indoor air include 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, 2,2,4-trimethylpentane, 4-ethyltoluene (p-ethyltoluene), benzene, ethanol, ethyl acetate, and n-heptane (**Table 2-6**).

All chemicals that were retained as COPCs were detected at maximum concentrations greater than the appropriate screening values (adjusted RSLs) if RSLs (or alternate values) were available. However, no RSL values were available for detected parameters 1,3-dichlorobenzene, methyl-cyclohexane, p-isopropyltoluene, t-butyl alcohol, 3-nitroaniline, carbazole, 3-methyl hexane, dimethyl sulfide, sulfur dioxide, and lead. Consequently, all of these parameters were selected as COPCs in one or more media with the exception of 3-nitroaniline and carbazole as they were eliminated due to low frequency of detection.

The final list of COPCs by media is presented in **Table 2-7**.

3.0 EXPOSURE ASSESSMENT

The condition of a chemical contacting the outer boundary of a human is exposure. Most of the time, the chemical is contained in air, water, soil, a product, or a transport or carrier medium; the chemical concentration at the point of contact is the exposure concentration. An exposure assessment is the quantitative or qualitative evaluation of that contact; it describes the intensity, frequency, and duration of contact, and often evaluates the rates at which the chemical crosses the boundary (chemical intake or uptake rates), the route by which it crosses the boundary (exposure route; e.g., dermal, oral, or respiratory), and the resulting amount of the chemical that actually crosses the boundary (a dose) and the amount absorbed (internal dose).

The objective of the exposure assessment is to estimate the type and magnitude of exposures to COPCs at or migrating from the Site. The exposure assessment includes the following components:

- Characterization of the exposure setting (including current and future land uses);
- Identification of exposure pathways (including receptor identification and exposure scenarios, and exposure points);
- Identification of EPCs;
- Quantification of exposures; and
- A summary of exposures by receptor and exposure point.

This section is organized to follow the bullets above (the sub-headings match the bullets above).

3.1 Exposure Setting

The exposure setting, including current and anticipated future land use at the property has been described in detail in Section 1.5.4 and in the CSM presented in Section 1.5. As described in these Sections, the property is commercial/industrial property with limited access.

3.2 Exposure Pathways

The following Sections identify the exposure pathways including receptors, exposure scenarios, and exposure areas.

3.2.1 Receptor Identification

Based on the current and assumed future land uses for the former CPS Property and the remainder of the CPS/Madison Superfund Site, receptors evaluated include a trespasser (on-Property surface and surface and subsurface soil), an outdoor commercial/industrial worker (on-Property surface and subsurface soil and groundwater), an indoor commercial/industrial worker (on-Property surface and subsurface soil and groundwater potable use and vapor intrusion and

at the Madison Industries Property for groundwater vapor intrusion), a construction worker (surface and subsurface soil and groundwater), a utility worker, and a hypothetical resident (surface and subsurface soil and groundwater).

3.2.2 Exposure Scenarios

Exposure scenarios are used to quantitatively describe the COPC exposures that could theoretically occur for each land use and exposure pathway evaluated. The exposure scenarios are used in conjunction with EPCs to derive quantitative estimates of COPC intake or exposure. The ultimate goal of developing exposure scenarios, as defined in USEPA guidance, is to identify the combination of exposure parameters that results in the most intense level of exposure that may "reasonably" be expected to occur under the current and future site conditions (USEPA, 1989). As such, a single exposure scenario is often selected to provide a conservative evaluation for the range of possible receptors and populations that could be exposed at the Site for a given land use. For example, when evaluating a theoretical residential land use, a residential scenario that is modeled to be protective for the children and adults who live at the residence (i.e., people who are there all the time) is assumed to be protective for all other receptor populations (such as friends, neighbors, and landscaper workers) and, therefore, it unnecessary to also evaluate those other, less-exposed, receptor populations.

The basis for the exposure scenarios that are used to evaluate health risks associated with the potentially complete exposure pathways under current and possible future land use conditions were described in Section 1.5.5, which identified receptors, and Section 1.5.6, which identified exposure media, and are summarized below:

- Trespasser: The former CPS Property is fenced; it is located in an industrial area. A trespasser would need to travel on roads through a heavily industrialized area at least one-half mile from the nearest residence to engage in trespassing activity. Thus, this BHHRA will evaluate risk posed to an adolescent trespasser (age range 12-<18 years old) and an adult trespasser (18-<30 years old), as a younger child is unlikely to engage in these activities. As indicated above, existing conditions make trespassing on a frequent basis unlikely. None-the-less, as directed by USEPA, an exposure frequency of 52 days per year was selected for the trespasser scenario. This scenario evaluates potential ingestion and dermal exposures to surface soil (0-2 ft bgs) at Area 1, Area 2, and Area 3 for current exposures. This scenario evaluates potential ingestion and dermal exposures to combined surface/subsurface soil (0-10 ft bgs) at Area 1, Area 2, and Area 3 for future exposures.
- Outdoor worker: The former CPS Property may be redeveloped for industrial use in the foreseeable future. This is a long-term receptor exposed during the work day who is a full-time employee of a company operating on-Property and who spends most of the workday conducting maintenance activities outdoors. The activities for this receptor (e.g., moderate digging, landscaping) typically involve on-Site exposures to surface soils. The worker is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal absorption of contaminants from soil, and inhalation of soil-derived fugitive dust. This scenario evaluates potential ingestion, dermal, and inhalation of particulates and assumes exposure to surface (0-2 ft bgs) and subsurface soil (0-10 ft

bgs) at Area 1, Area 2, and Area 3. Additionally, this receptor is evaluated for limited ingestion of groundwater from the CPS/Madison Plume (consistent with hypothetical potable use of groundwater). The outdoor worker would not be expected to have any future dermal or inhalation exposures associated with groundwater.

- Indoor worker: The former CPS Property may be redeveloped for industrial use in the foreseeable future. This receptor spends most, if not all, of the workday indoors; therefore exposure to soil is limited. However, per USEPA guidance, some exposure to soil is assumed. The indoor commercial/industrial worker is assumed to be exposed to soils via incidental ingestion of soil and dermal absorption of contaminants from soil. This scenario evaluates potential ingestion and dermal exposures to surface (0-2 ft bgs) and combined surface/subsurface soil (0-10 ft bgs) at Area 1, Area 2, and Area 3 for future exposures. . Additionally, this receptor is evaluated for limited ingestion of groundwater within the CPS/Madison Plume (consistent with hypothetical potable use of groundwater). Also, vapor intrusion from shallow groundwater has been evaluated for this receptor.
- Construction and excavation workers who develop the former CPS Property, or who may perform additional building construction (e.g., building additions) after initial development. This receptor is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal contact with soil, and inhalation of fugitive dust. This scenario evaluates potential ingestion, dermal, and inhalation of particulate exposures to combined surface/subsurface soil (0-10 ft bgs) at Area 1, Area 2, and Area 3 for future exposures. Additionally, this receptor could be exposed to shallow groundwater at the former CPS Property. This receptor is evaluated for limited incidental groundwater ingestion, dermal contact with groundwater, and inhalation of volatiles released from shallow groundwater during excavation activities within Area 1, Area 2, and Area 3.
- A construction/utility worker is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal contact with soil, and inhalation of fugitive dust. This scenario evaluates potential ingestion and dermal exposures to soil (0-10 ft bgs) within the sewer line exposure area. Additionally, this receptor is evaluated for limited incidental ingestion of shallow groundwater, dermal contact with groundwater, and inhalation of volatiles potentially released from shallow groundwater within the vicinity of the sewer line.
- A hypothetical future resident scenario for the former CPS Property evaluates a child and adult assuming the property is redeveloped as a residence in the future. This scenario evaluates potential ingestion and dermal exposures to surface (0-2 ft bgs) and combined surface/subsurface soil (0-10 ft bgs) within Area 1, Area 2, and Area 3. Additionally, this hypothetical receptor is assumed to be exposed to groundwater within the CPS/Madison Plume used for potable purposes (ingestion, dermal contact, and inhalation of volatiles released during showering.

Exposures to COPCs are quantified by using numerical parameters that include ingestion rates, dermal contact areas, body weights, exposure times, exposure frequencies, and exposure durations, which are defined below. These parameters and the sources of their values are documented in **Tables 3-13** through **3-15**. The specific numerical values for each of these parameters are selected in consideration of the receptor activities and ages that the exposure

scenarios are modeling, and are generally selected as the upper-end (generally 95th percentile) values for each quantitative parameter. Using receptor scenarios that are protective for all potentially exposed populations associated with a given land use, with numerical parameters that are generally based on the upper-end distributions, results in exposure scenarios are referred to as the Reasonable Maximum Exposure (RME). Exposure parameters are developed from USEPA national guidance (USEPA, 1997a; 1994; 2002a; 2002b; 2004; 2011). The exposure parameters used to quantify exposures for each of the scenarios described in this section are provided in RAGS Part D 'Tables 4's, which are presented as **Tables 3-13** through **3-15**. These Tables provide a summary of the exposure scenarios and key exposure parameters that are used to quantify COPC exposures at each of the EAs. For this BHHRA, the showering/bathing exposure will be evaluated using the Andelman as modified by Schaum et. al. shower model (Schaum et. al., 1994).

3.2.3 Exposure Areas (EA)

The exposure media evaluated quantitatively in the BHHRA include surface soil, subsurface soil, groundwater within the CPS plume, on-Site shallow groundwater, and indoor air.

EAs have been identified based on the current and foreseeable future land uses and activities and physical characteristics of the former CPS Property. The soil exposure areas have been identified as Area 1, Area 2, Area 3, and Soils within the Sewer Line Area. Within the soil exposure areas, various depth intervals were considered for different receptors (further explained below). The groundwater exposure areas have been identified as within the VOC and metals Plume, and Area 1, Area 2, Area 3. **Figure 1-3** depicts the former CPS Property exposure areas, **Figure 1-6** depicts the soil sampling locations within each exposure area, **Figure 1-7** depicts soil vapor and indoor air sampling locations, **Figure 1-8** depicts the shallow groundwater sampling locations within each exposure area (considered in the vapor intrusion assessment and the construction worker scenario), and **Figure 1-9** depicts the CPS / Madison Superfund Site monitoring well locations..

Each exposure area identified above is further described below. Within each exposure area, a summary of the datasets used to evaluate individual exposure points is presented as well:

- Area 1 – This exposure area consists of the location where chemical processing operations occurred. This area is located hydraulically downgradient of Areas 2 and 3. Within Area 1 the following exposure points will be evaluated:
  - Surface Soils (Area 1 soils between 0 to 2 ft bgs)
  - Surface and Subsurface Soils (Area 1 soils between 0 to 10 ft bgs)
  - Groundwater (Area 1 shallow groundwater)
- Area 2 – This exposure area consists of the locations associated with support activities, including a laboratory, office space, and storage facilities. Within Area 2 the following exposure points were evaluated:
  - Surface Soils (Area 2 soils between 0 to 2 ft bgs)
  - Surface and Subsurface Soils (Area 2 soils between 0 to 10 ft bgs)

  - Groundwater (Area 2 shallow groundwater)
- Area 3 – This exposure area consists of the undeveloped side-lot that has never been used for production activities. Within Area 3 the following exposure points were evaluated:
  - Surface Soils (Area 3 soils between 0 to 2 ft bgs)
  - Surface and Subsurface Soils (Area 3 soils between 0 to 10 ft bgs)
  - Groundwater (Area 3 shallow groundwater)
- Sewer Line Area – This exposure area consists of soils in the vicinity of the sewer line that traverses the CPS Site. Soils that fall within 5 feet on either side of the Sewer Line could be considered representative of soils that a worker performing maintenance on the sewer line could contact. However, due to the limited dataset within that area, this area was expanded to 10 feet on either side of the Sewer Line. Refer to **Figure 1-6** for the sewer line location. Similarly, soils that are located between 0 to 6 ft bgs in depth would typically be considered representative of soil that a worker performing maintenance of the sewer line could contact. However, due to the limited dataset within that depth interval, soils within 0 to 10 ft bgs were considered for this exposure point.
- CPS/Madison Plume – This exposure area consists of groundwater representative of current conditions within the CPS/Madison Plume. The RI characterized the CPS/Madison plume, and it is fully delineated by the existing well network both in terms of concentration magnitude and extent. Given that groundwater concentrations fluctuate, and those at the former CPS Property have been decreasing over time, recent validated groundwater concentrations were considered. Additionally, only groundwater data collected from monitoring wells or extraction wells was considered representative of this exposure point. Thus, the most recent groundwater data (by parameter) collected from a monitoring well within the CPS/Madison Plume was considered for this exposure point. While dissolved metals data are generally representative of the concentrations that a receptor would be exposed to from a potable water supply (potable groundwater would be filtered as part of treatment prior to use) the most recent total metals data were selected. The risk assessment represents a conservative estimate of exposure to groundwater.

Table 1-6 provides a summary of the receptors and exposure scenarios evaluated in the BHHRA.

3.2.4 Incomplete Exposure Pathways

The RI data collected to date suggest that exposure to surface water and sediment and volatiles in indoor air as a result of vapor intrusion are not complete. COPCs were screened for volatile constituents in groundwater discharging to surface water. The results of the COPC screening will be used to support a qualitative discussion regarding exposure to surface water. Sediment will not be evaluated in this BHHRA, as volatiles are the COI for the Site and are not anticipated to accumulate in sediment. Additionally, minimal exposure to sediment both on- or off-Site is anticipated.

Using multiple lines of evidence, the vapor intrusion pathway was determined to be incomplete.

3.3 Exposure Point Concentrations (EPCs)

The USEPA defines the EPC as the representative medium-specific chemical concentration a receptor may contact at an exposure point over the exposure period (USEPA, 1989). Separate EPCs are calculated for each exposure medium at each exposure point. The typical concept of human exposure within a defined exposure area is that an individual contacts the contaminated medium on a periodic and random basis. Because of the repeated nature of such contact, the human exposure does not really occur at a fixed point but rather at a variety of points with equal likelihood that any given point within the exposure area will be the contact location on any given day. Thus, exposure areas were identified considering the likelihood of a receptor contacting all areas within the exposure area with equal probability, as reflected in EPCs based on arithmetic averages of the chemical concentrations within the exposure area. However, to account for uncertainty in estimating the arithmetic mean concentration, the USEPA recommends that an UCL on the mean be used to represent the EPC.

In accordance with USEPA guidance, Reasonable Maximum Exposure (RME) EPCs are based on the lower of the 95 percent UCL on the arithmetic mean concentration (95% UCL value) or the maximum detected concentration in the data set (USEPA, 2002b).

The 95% UCL values are calculated using the ProUCL software (Version 5.0, USEPA, 2010). The ProUCL software performs a goodness-of-fit test for data sets with or without non-detects to identify the distribution type for the data set (e.g., normal, lognormal, gamma, or non-discernable), and then calculates a conservative and stable 95 percent UCL value in accordance with the framework described in “Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites” (USEPA, 2002b). The software includes numerous algorithms for calculating 95% UCL values, and provides a recommended UCL value based on the algorithm that is most applicable to the statistical nature of the data set.

EPCs were calculated as follows for each exposure point within each exposure area. All EPCs are identified in ‘RAGS Part D Table 3s’:

- **Table 3-1**, **3-2**, and **3-3** present the calculation of EPCs for surface soils (0-2 ft bgs) within Areas 1, 2, and 3, respectively. These exposure points will be used to evaluate risk to a current trespasser exposed to each individual exposure area. The EPCs for these exposure points are based on the lower of the 95% UCL and the maximum detected concentrations. For Area 2, the 95% UCLs for benzene and tetrachloroethylene were lower than the arithmetic mean (raising questions about the validity of the calculated upper confidence limit on that mean); for these two analytes, the maximum detected concentrations were selected as the EPCs in lieu of the 95% UCL. When all analytical results were non-detect, an EPC was not calculated.
- **Table 3-4**, **3-5**, and **3-6** present the calculation of EPCs for combined soils (0-10 ft bgs) within Areas 1, 2, and 3, respectively. These exposure points will be used to evaluate risk to a future commercial/industrial worker exposed to each individual exposure area. This depth interval was selected as it accounts for the possibility of moving soils from the subsurface to the surface under a future scenario. The EPCs for these exposure points are based on the lower of the 95% UCL and the maximum detected concentrations. When

all analytical results were non-detect, an EPC was not calculated. Additionally, p-isopropyltoluene was not analyzed in the dataset for Area 3; thus, an EPC was not calculated.

- **Table 3-7** presents the calculation of EPCs for soils within the Sewer Line Exposure Area. The depth of soils considered in this exposure area is 0 to 10 ft bgs. This exposure point is evaluated to address exposure to a utility worker performing maintenance on the Sewer Line. Due to the limited soil data within this exposure point, the EPCs are equal to the maximum detected concentrations within the exposure point. When all analytical results were non-detect, an EPC was not calculated.
- **Table 3-8** presents the calculation of EPCs for groundwater within the CPS/Madison Plume. The EPCs for these exposure points are based on the lower of the 95% UCL and the maximum detected concentrations. When 95% UCLs could not be calculated due to a limited dataset, the maximum detected concentration was selected as the EPC. Additionally, as a conservative measure, total metals concentrations were used to calculate EPCs.
- **Table 3-9, 3-10, and 3-11** present the calculation of EPCs for shallow groundwater within Areas 1, 2, and 3, respectively. These exposure points will be used to evaluate exposure to a construction worker performing work in each individual exposure area. Due to a limited data set, 95% UCLs were not calculated. Instead, maximum detected concentrations were selected as EPCs. When an analyte was not-detected in an Area, no EPC was identified.
- **Table 3-12** presents the calculation of EPCs for indoor air at the former CPS Property (Area 2 vacant building). This exposure point will be used to evaluate an indoor worker's exposure to indoor air. Due to a limited data set (small number of samples), 95% UCLs were not calculated. Instead, maximum detected concentrations were selected as EPCs.
- **Table 3-16** presents the calculation of the volatilization factor for the release of vapors from shallow groundwater in an excavation to ambient air in a trench for a construction worker. **Tables 3-17, 3-18, and 3-19** present the ambient air concentrations in a trench for areas 1, 2, and 3 respectively.

Attachment A presents the analytical data considered for each of these exposure points. ProUCL output sheets are provided in **Attachment F**.

EPCs may be based on COPC concentrations that are directly measured, or on COPC concentrations that are estimated via modeling. EPCs that are used to quantify ingestion and dermal contact exposures are based on measured concentration data. Since the true exposure medium for evaluation of inhalation exposures is air, and limited analytical data for air were collected, EPCs that are used to evaluate inhalation exposures will be modeled from source media concentrations. Inhalation exposure to soil-derived dust will be evaluated for outdoor workers and construction workers. The source media for dust is soil, and the soil EPCs are used as the 'source' concentrations for estimating dust-associated COPC concentrations in air.

3.4 Exposure Quantification

The calculation of cancer risk and non-cancer HQs requires the quantification of exposure (either as a dose (or intake) or as a representative concentration). Exposures to COPCs are quantified by calculating COPC-specific doses (or intakes) (ingestion and dermal contact) or representative concentrations (air/inhalation exposures) for the receptors at the various exposure points or exposure areas for current and possible future land uses. This section describes the process that is used to quantify COPC exposure for ingestion and dermal contact with soil, groundwater, indoor air, and for soil-related dust. The quantification of exposures is based on the specifics of the exposure scenarios for the receptors evaluated.

Exposures are quantified in two major ways – via the calculation of a daily intake (oral and dermal exposures) or by calculating a representative exposure concentration (inhalation).

By combining the EPC and the receptor exposure parameters, the daily dose (soil, surface water, sediment) or representative exposure concentration (air) is calculated. Those measures of exposure are subsequently used with toxicity values to characterize health risks.

Fundamentally, the calculated dose/intake is a function of EPC and exposure parameters:

Dose/Intake = (EPC) x (Exposure Parameters)

For ingestion and dermal exposure routes, the general equation for calculating intake is as follows:

$$Dose = \frac{EPC \times CR \times EF \times ED}{AT \times BW}$$

Where:

Dose	=	Average daily dose of COPC from soil at the exposure point during the period of exposure (mg/kg/day)
EPC	=	Exposure Point Concentration (mg/kg or mg/L)
CR	=	Contact Rate (mg/day)
		Ingestion: Ingestion rate (mg/day)
		Dermal absorption: Skin surface area (cm^2/day) x adherence factor (mg/cm^2) [soil and sediment only] x absorption factor (unitless)
EF	=	Exposure Frequency (days/year)
ED	=	Exposure Duration (years)
AT	=	Averaging Time (days) (equal to ED for non-cancer evaluation; equal to 70 years for cancer evaluation)
BW	=	Body Weight (kg)

The ingestion exposure calculations reflect the applied dose (amount of the COPC in the mass of the medium that is ingested), not the dose absorbed through the gastrointestinal tract. Oral dose-response values are used to evaluate those doses. For dermal exposure calculations, the general equation format shown above is supplemented by calculations of the absorbed dose. Dermal dose-response values are used to evaluate the dermal doses. The dose rate is typically expressed as a bodyweight-normalized dose for risk calculations (mass per time per unit bodyweight or mg/kg-bw/day). Dose is calculated as an average daily dose for non-cancer risk calculations and as a lifetime average daily dose for cancer risk calculations. The calculated doses are conservative because they are calculated using EPCs that are conservative estimates of average concentrations (95% UCLs on the mean or the maximum detected concentration if it is lower than the 95% UCL).

The methodology for evaluating inhalation exposures differs from that used for the ingestion and dermal routes because toxic effects associated with inhalation exposures are a function of the COPC *concentration* in air rather than of the *intake/dose* as is the case for ingestion and dermal exposures. Hence, inhalation exposures are quantified in terms of average COPC concentration in air over the exposure period for non-cancer risk calculations and the lifetime average COPC concentration in air for cancer risk calculations. The exposure-response values used to calculate these risks are Reference Concentrations (RfCs) presented in dimensions of milligrams per cubic meter (mg/m^3) and Inhalation Unit Risks (IURs) presented in dimensions of (micrograms per cubic meter [$\mu g/m^3$])$^{-1}$ instead of Reference Doses (RfDs) and Cancer Slope Factors (CSFs). Because a representative concentration and not dose is the basis for inhalation risk assessment, exposure parameters such as body weight and ventilation rate are not typically used in calculating risk estimates for inhalation exposures (USEPA, 2009). The general equation for calculating chemical exposure via inhalation is as follows:

$$ECair = \frac{CA \times ET \times EF \times ED}{CF \times AT}$$

Where:

ECair	=	representative concentration of COPC in the air at the exposure point during the period of exposure (mg/m^3)
CA	=	concentration of the COPC in air (mg/m^3)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (years)
ET	=	exposure time (hours/day)
CF	=	conversion factor (24 hours/day)
AT	=	averaging time (for carcinogens, AT = 70 years times 365 days per year; for noncarcinogens, AT = ED times 365 days per year).

The specific equations used to calculate doses/intakes for soil, surface water, and exposures for inhalation of soil-derived dust are those presented in USEPA guidance (USEPA, 1989; 2004;

2009), and are provided in the exposure parameter **Tables 3-13** through **3-15**. **Table 3-20** presents exposure parameters for indoor air.

Documentation of the quantitation of exposures is included in the RAGS Part D Table 7s and Table 9s in **Attachment G and H** respectively. Each attachment includes a list of tables to assist the reader in navigating the numerous tables. The tables in **Attachment G and H** are organized and ordered by soil exposure point and receptor. Each table includes exposure and risk calculations for all exposure media and exposure routes for a single receptor (e.g., Area 1 surface soil, outdoor worker, soil ingestion, dermal contact, and inhalation of dust and ingestion of groundwater (occupational potable water). In **Attachment G and in Attachment H** there are tables of contents that summarize the risk calculation tables (RAGS Part D table 7s in **Attachment G** and the RAGS Part D table 9s in **Attachment H**), identifying, for each risk calculation table, the surface depth/exposure point combination, the receptor, the receptor age group (as applicable), the exposure media, and the exposure routes.

- Area 1 Surface soil
- Area 2 surface soil

- Sewer line Area 1 combined soil
- Sewer line Area 2 combined soil
- Sewer line Area 3 combined soil

4.0 TOXICITY ASSESSMENT

The objective of the toxicity assessment is to quantify the relationship between the intake, or dose, of COPCs and the likelihood that adverse health effects may result from exposure to the COPCs.

The BHHRA evaluates non-carcinogenic and carcinogenic health effects. Non-carcinogenic health effects refer to toxicological effects other than cancer which may result from exposure to a substance, such as toxicity to the liver, skin, or central nervous system. Carcinogenic health effects refer to the development of cancer which may result from exposure to a substance. Following USEPA guidance (USEPA, 1989), the risks of non-carcinogenic and carcinogenic effects are evaluated separately.

There are separate toxicity values, or dose-response values, for evaluating health risks: CSFs and UR values for carcinogens; and RfDs and RfCs for non-carcinogens. For potentially carcinogenic COPCs, both types of values have been developed by USEPA because these COPCs may elicit both carcinogenic and non-carcinogenic (systemic) effects. In addition, because toxicity and/or carcinogenicity can depend on the route of exposure (i.e., oral or inhalation), unique dose-response values have been developed for the oral, dermal, and inhalation exposure routes.

Section 4.1 describes the types of toxicity values that are used for evaluation of cancer risks, and Section 4.2 describes the types of toxicity values that are used for evaluation of non-cancer hazards.

4.1 Toxicity Assessment for Carcinogenic Effects

The toxicity assessment followed the USEPA two-part evaluation to characterize the carcinogenicity of a chemical. The first part involves assigning a weight-of-evidence classification to a chemical, which describes the strength of available information with respect to the association of chemical exposure and human cancer. The second part involves calculation of a CSF or UR to reflect the carcinogenic potency.

4.1.1 Weight-of-Evidence

Historically, USEPA has used an alphanumeric system to describe the weight-of-evidence:

Group A - Human Carcinogen. This category indicates there is sufficient evidence from epidemiological studies to support a causal association between an agent and human cancer.

Group B - Probable Human Carcinogen. This category generally indicates there is at least limited evidence from epidemiologic studies of carcinogenicity to humans (Group B1) or that, in the absence of data on humans, there is sufficient evidence of carcinogenicity in animals (Group B2).

Group C - Possible Human Carcinogen. This category indicates that there is limited evidence of carcinogenicity in animals in the absence of data on humans.

Group D - Not Classified. This category indicates that the evidence for carcinogenicity in animals is inadequate.

Group E - No Evidence of Carcinogenicity to Humans. This category indicates that there is evidence of noncarcinogenicity in at least two adequate animal tests in different species or in both epidemiologic and animal studies.

This assessment also followed the revised Guidelines for Carcinogenic Risk Assessment (USEPA, 2005c), wherein USEPA revised the approach to describing the carcinogenic potential of an agent from an alphanumeric system to a weight-of-evidence-based descriptive narrative. Descriptors are as follows:

Carcinogenic to Humans. This descriptor indicates strong evidence of human carcinogenicity, and is appropriate A) when there is convincing epidemiologic evidence of a causal association between human exposure and cancer; or B) when all of the following conditions are met: (a) there is strong evidence of an association between human exposure and either cancer or the key precursor events of the agent's mode of action but not enough for a causal association, and (b) there is extensive evidence of carcinogenicity in animals, and (c) the mode(s) of carcinogenic action and associated key precursor events have been identified in animals, and (d) there is strong evidence that the key precursor events that precede the cancer response in animals are anticipated to occur in humans and progress to tumors, based on available biological information.

Likely to be Carcinogenic to Humans. This descriptor is appropriate when the weight of the evidence is adequate to demonstrate carcinogenic potential to humans but does not reach the weight of evidence for the descriptor “Carcinogenic to Humans”. The use of the term “likely” as a weight of evidence descriptor does not correspond to a quantifiable probability. Supporting data for this descriptor may include: an agent demonstrating a plausible (but not definitively causal) association between human exposure and cancer, in most cases with some supporting biological, experimental evidence, though not necessarily carcinogenicity data from animal experiments; an agent that has tested positive in animal experiments in more than one species, sex, strain, site, or exposure route, with or without evidence of carcinogenicity in humans; a positive tumor study that raises additional biological concerns beyond that of a statistically significant result, for example, a high degree of malignancy, or an early age at onset; a rare animal tumor response in a single experiment that is assumed to be relevant to humans; or a positive tumor study that is strengthened by other lines of evidence, for example, either plausible (but not definitively causal) association between human exposure and cancer or evidence that the agent or an important metabolite causes events generally known to be associated with tumor formation (such as DNA reactivity or effects on cell growth control) likely to be related to the tumor response in this case.

Suggestive Evidence of Carcinogenic Potential. This descriptor is appropriate when the weight of evidence is suggestive of carcinogenicity; a concern for potential carcinogenic effects in humans is raised, but the data are judged not sufficient for a stronger conclusion. This descriptor covers a spectrum of evidence associated with varying levels of concern for carcinogenicity, ranging from a positive cancer result in the only study on an agent to a single positive cancer result in an extensive database that includes negative studies in other species.

Data Inadequate for an Assessment of Human Carcinogenic Potential. This descriptor is appropriate when available data are judged inadequate for applying one of the other descriptors.

Not Likely to be Carcinogenic in Humans. This descriptor is appropriate when the available data are considered robust for deciding that there is no basis for human hazard concern. In some instances, there can be positive results in experimental animals when there is strong, consistent evidence that each mode of action in experimental animals does not operate in humans. In other cases, there can be convincing evidence in both humans and animals that the agent is not carcinogenic.

The weight of evidence classification in Integrated Risk Information System (IRIS) for a given chemical may reflect either of the two classification schemes identified above, depending on when USEPA most recently reviewed and revised the carcinogenicity assessment for any given chemical.

4.1.2 Carcinogenic Potency

It has been generally assumed historically that carcinogenic effects are non-threshold effects. This means that any dose, no matter how small, has been assumed to pose a finite probability of generating a response. Thus, no dose of a carcinogen has been thought to be risk-free. More contemporary evaluations that focus on the mechanisms of action by which a chemical may cause cancer have, for some chemicals, identified threshold doses below which carcinogenesis does not occur. In consideration of the nature of the toxicological data that are available for a given chemical, USEPA uses one or more of several different models to identify the relationship between the dose of the chemical and a carcinogenic response.

The toxicological data that are used to evaluate carcinogenic potency generally come from cancer bioassays that are performed using laboratory animals such as specific strains of rats and mice. An advantage of using laboratory animals to identify dose-response relationships is that the substances and doses that the animals are exposed to are controlled, such that if a carcinogenic response occurs, there is more confidence that the response occurred as a result of exposure to a specific substance, and the doses that caused the response are known. Disadvantages of using animal studies include uncertainties with extrapolating a carcinogenic response in animals to a carcinogenic response in humans. This uncertainty is addressed, in part, through the use of relatively high doses of chemicals used in cancer bioassays. Generally, laboratory animals are given maximum tolerated doses (i.e., the highest dose that the animal can tolerate without suffering adverse effects that would otherwise compromise the study) and fractions of the maximum tolerated dose. These doses are typically much higher than any dose that would be experienced by human populations. If a positive dose-response relationship is not identified in animal studies that use these high doses, then there is more confidence that the substance would not cause cancer at the much lower exposure levels potentially experienced by human populations. In contrast, if a positive dose-response relationship is identified in animal studies that use high doses, there is uncertainty in extrapolating the dose-response relationship from high doses to the much lower exposure levels potentially experienced by human populations.

Consequently, human epidemiologic data are a preferred basis for developing estimates of carcinogenic potency. However, the majority of chemicals studied to do not have sufficient

epidemiological study data to allow for derivation of dose-response relationships. Many epidemiology studies find causal relationships between exposure to a chemical and a toxicological response, but are confounded by the fact that human populations are exposed to many substances over a lifetime, as well as by the uncertainty inherent in measuring actual human exposures to specific substances (e.g., actual concentrations in workplace air that a population may have been exposed to over a period of many years). These uncertainties often preclude establishing a dose-response relationship that is sufficient to use as the basis of carcinogenic potency estimates. Since laboratory bioassays avoid these uncertainties, they are often used as basis for the derivation of dose-response profiles, despite the availability of human epidemiological data.

The common measures of cancer potency assessment are the CSF (ingestion and dermal exposure) or a UR (commonly applied to inhalation, but also to ingestion (of drinking water)). The CSF is the estimated upper-bound excess lifetime cancer risk (ELCR) associated with a lifetime average daily dose of a chemical agent of 1 mg/kg/day and the inhalation UR is the upper-bound ELCR associated with a lifetime average daily exposure of 1 $\mu g/m^3$ in air. CSF values are expressed as risk per mg/kg/day [$(mg/kg/day)^{-1}$] and UR values are expressed as risk per ($\mu g/m^3$) [$(\mu g/m^3)^{-1}$]. USEPA and other regulatory and scientific organizations have typically calculated CSFs and URs for chemicals in weight of evidence Groups A, B1, B2, and "Carcinogenic to humans" and "Likely to be carcinogenic to humans". For some, but not all chemicals with Group C weight of evidence classification, USEPA and other organizations have also calculated cancer dose-response values.

In this BHHRA, CSFs are used to estimate the incremental risks associated with ingestion and dermal exposures, and URs are used to estimate the cancer risks associated with inhalation of COPCs in air (airborne dust).

The CSF and UR values and supporting documentation are provided in **Tables 4-1** and **4-2**.

4.1.3 Adjustment for Early Life Exposures to Carcinogens with a Mutagenic Mode of Action

USEPA has developed guidance for characterizing cancer susceptibility associated with early life exposures (e.g., young children) to potentially carcinogenic chemicals (USEPA, 2005c; 2008a). The approach developed by USEPA to characterize cancer risks for early life stages includes consideration of differences in physiology and exposure potential between children and adults, as well as differences in susceptibility to tumor development between children and adults. Physiological and behavioral differences are accounted for in the exposure assessment, whereby age-specific exposure parameters (e.g., body weights, ingestion rates, inhalation rates, contact frequencies) are applied to the various age groups evaluated in the risk assessment. Differences in susceptibility to tumor development are accounted for by considering the carcinogenic mode of action in accordance with the mode of action framework developed by USEPA (USEPA, 2005c).

Consistent with USEPA guidance, an Age-Dependent Adjustment Factor (ADAF) has been applied to published CSFs for specific COPCs to calculate risk for the adolescent receptors. For this BHHRA, the receptors that includes child exposures is the trespasser scenario (adolescent trespasser from age 12 to18 years) and the residential scenario (Child ages 1-6). Carcinogenic

COPCs with an identified mutagenic mode of action for media at the CPS Site include: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene,, indeno(1,2,3-cd)pyrene, methylene chloride, trichloroethylene, and vinyl chloride. Therefore, the CSFs for each of those COPCs will be adjusted for specific age groups to account for the mutagenic mode of action.

In general, USEPA-published slope factors are multiplied by generic age-dependent adjustment factors (ADAFs) as follows:

- ADAF for children 0<2 (ADAF=10)
- ADAF for children 2<6 (ADAF=3)
- ADAF for older children 6 < 16 yrs of age (ADAF = 3)
- Adults (>16 yrs of age) (ADAF = 1)

For the purposes of this risk assessment, weighted ADAFs have been applied as follows:

- Children 1-6 years old: ADAF of 5.3, calculated as an age-weighted ADAF for children 0<2 (ADAF=10) and children 2<6 (ADAF=3), as follows: [(2 yrs x 10) + (3 yrs x 4)] / 6 yrs = 5.3
- Adolescents 12-18 years old: ADAF of 2.3 calculated as an age-weighted ADAF for older children 12<16 (ADAF=3) and adults 16<18 (ADAF=1), as follows: [(4 yrs x 3) + (2 yrs x 1)] / 6 yrs = 2.3

Trichloroethylene is carcinogenic by a mutagenic mode of action for induction of kidney tumors (USEPA, 2013c). The oral slope factor and inhalation unit risk toxicity values published in IRIS incorporate risk due to three cancer types, kidney, non-Hodgkin lymphoma (NHL), and liver and these values do not reflect the presumed increased early-life susceptibility to kidney tumors. In order to account for the increased early-life susceptibility to kidney tumors, the kidney cancer component of the TCE CSF and UR has been adjusted using the ADAFs presented above. The published CSF and URs are presented in **Tables 4-1** and **4-2** and the adjusted CSFs and URs for trichloroethylene by age range are presented in **Tables 4-3** and **4-4**.

4.2 Toxicity Assessment for Non-Carcinogenic Effects

Unlike carcinogenic effects, non-carcinogenic effects are threshold effects and were evaluated accordingly. This means that at some level of exposure there is a threshold below which adverse effects would not be expected, and above which adverse effects could potentially occur. Examples of non-carcinogenic (i.e., threshold) effects include liver toxicity, kidney toxicity, reproductive effects, neurotoxicity, and teratogenicity. The same process that is used to identify toxicity data to support carcinogenic potency assessment is also used to identify toxicity data to support the identification of dose-response relationships for non-carcinogenic effects.

Non-cancer toxicity values include RfDs and RfCs. The RfD expressed in units of mg/kg/day, is defined as an estimate (with uncertainty spanning perhaps an order of magnitude or greater) of a daily exposure level for the human population, including sensitive subpopulations, that is likely to

be without an appreciable risk of deleterious effects during a lifetime (USEPA, 1989). Unlike a CSF or UR, which represents a probability of incurring a carcinogenic effect following exposure to a substance, the RfD represents a threshold dose below which adverse health effects are unlikely to occur, and above which the potential for adverse health effects exists. The RfD is derived from the following equation:

$$RfD\ (mg/kg/day) = \frac{NOAEL\ or\ LOAEL}{UF\ and/or\ MF}$$

The No Observed Adverse Effect Level (NOAEL) represents the dose of a chemical at which there are no statistically or biologically significant differences in the frequency of an adverse effect between the exposed population and its appropriate control. The Lowest Observed Adverse Effect Level (LOAEL) represents the lowest dose at which a statistically significant difference in the frequency of an effect is noted. Both the NOAEL and the LOAEL are reported in terms of mg/kg/day. An uncertainty factor (UF) is used to account for inter-species and intra-species differences, whether the dose was an NOAEL or an LOAEL, and the adequacy of the data. The magnitude of the UF will therefore vary from chemical to chemical, ranging from 3 to 3,000. A modifying factor (MF), ranging from 1 to 10 may also be included to reflect qualitative uncertainties not explicitly addressed in the UFs. The toxicity endpoint upon which the RfD is derived and the UF and/or MF used in the calculation are presented in the dose-response tables provided in **Table 4-5**.

The RfC, in units of mg/m^3, is analogous to the RfD and is developed through a similar process. However, unlike RfDs, which represent a dose (in mg/kg/day) at which adverse or deleterious effects are unlikely, RfCs represent air concentrations (in mg/m^3) at which adverse or deleterious effects are unlikely (i.e., an air concentration corresponding to a hazard index (HI) = 1.0). In this BHHRA, inhalation RfCs are used to estimate the non-cancer risks associated with inhaling COPCs.

The use of chronic RfDs and RfCs to evaluate the potential for adverse health effects resulting from substantially less-than-lifetime exposures may be overly protective. Subchronic Reference Doses and Subchronic Reference Concentrations (RfD_ss/RfC_ss) have been developed for some chemicals to evaluate the potential non-carcinogenic effects of limited duration exposures. RfD_ss/RfC_ss are similar to chronic RfDs/RfCs; the distinction is the length of exposure duration. The construction worker scenario is the only scenario evaluated in this risk assessment that is associated with subchronic exposures. Therefore, when available, subchronic RfDs and RfCs are used to evaluate potential non-cancer risks for the construction worker. When subchronic values are not available, chronic RfDs and RfCs are used. Chronic RfDs and RfCs are used for all other receptor scenarios.

The RfDs and RfCs and supporting documentation for the chemicals selected as COPCs are provided in **Tables 4-5 and 4-6**.

4.2.1 Adjustment for Dermal Exposure

Oral Cancer CSFs and non-cancer RfDs were developed to evaluate risk associated with the ingestion exposure route (typically based on the applied dose). In accordance with USEPA

guidance (USEPA, 2004), dermal dose-response values are calculated from oral dose-response values using an oral absorption factor. The dermal dose-response values are appropriate for evaluating the calculated absorbed dose associated with dermal exposures. The oral absorption factor represents the fraction of ingested amount that is absorbed from the gastrointestinal tract following oral administration of a substance. The absorbed dose represents the amount of substance that is potentially available for biological interaction. The calculated dermal dose-response value is appropriate for evaluating the absorbed dermal doses.

Thus, for potentially carcinogenic substances, the dermal dose-response value is calculated as follows:

$$CSF_d = CSF_o / Oral\ ABS$$

The dermal dose-response value for evaluating non-carcinogenic effects is calculated as follows:

$$RfD_d = RfD_o\ X\ Oral\ ABS$$

Chemical-specific oral ABS values are published by USEPA (USEPA, 2004). In accordance with USEPA guidance (USEPA, 2004), oral dose-response values are only adjusted using an oral ABS value if the COPC has an oral ABS value less than 50 percent. Otherwise, the oral dose-response value is used as the dermal dose-response value.

Dermal RfDs and CSFs are presented in **Tables 4-5 and 4-1**.

4.2.2 Chemical-Specific Considerations

For some constituents, RfD values differ by exposure medium and/or chemical speciation or form. These attributes apply to the following COPCs in this BHHRA:

Cadmium. USEPA publishes two RfD values for cadmium: one is to be used to evaluate cadmium in food, and one is to be used to evaluate cadmium in water. The RfD for food was used for soil exposures and the RfD for water has been used to evaluate risks for exposures to cadmium in groundwater.

Chromium. USEPA publishes separate RfD values for hexavalent chromium and trivalent chromium. Based on USEPA RfDs, hexavalent chromium is associated with a higher order of non-cancer toxicity than is trivalent chromium. An inhalation UR for hexavalent chromium is published in USEPA's IRIS database. There is currently no oral CSF for hexavalent chromium published in the USEPA IRIS database. Chromium is not a COI at the Site, and chromium has not been used in historical operations at the Site. Although chromium has been selected as COPC at the Site, hexavalent chromium is not anticipated at the Site. Therefore, the toxicity values for trivalent chromium will be used in this BHHRA.

4.3 Sources of Dose-Response Values

The following hierarchy of sources for dose-response values (USEPA, 2003a) has been utilized in identifying dose-response values for this BHHRA.

Tier 1 - IRIS (http://www.epa.gov/iris/). In accordance with USEPA guidance, the main source of dose-response values is IRIS, which is a database established by USEPA containing all validated data on many toxic substances found at hazardous waste sites. This database (USEPA, 2013c), current as of November 2013, was used to identify the CSFs, URs, RfDs, and RfCs applied in this risk assessment.

Tier 2 - National Center for Environmental Assessment (NCEA) provisional peer reviewed toxicity values (PPRTVs) **(http://hhpprtv.ornl.gov/)**. NCEA's PPRTVs are developed by the Superfund Technical Support Center (STSC) for the USEPA Superfund program. STSC's reassessment of USEPA Health Effects Assessment Summary Tables (HEAST) toxicity values, as well as development of PPRTVs in response to Regional or Headquarters Superfund program requests, are consistent with Agency practices on toxicity value development, use the most recent scientific literature, and are supported by both internal and external peer review, providing a high level of confidence in the use of these values in the Superfund Program. The PPRTVs used in this HHRA were obtained from the USEPA-recommended website and are current as of November 2013.

Tier 3 - Other Toxicity Values:

- California Environmental Protection Agency (CALEPA) toxicity values (CALEPA, 2013). CALEPA develops toxicity values for both cancer and non-cancer effects. CALEPA toxicity values were obtained from the CALEPA website at http://www.oehha.ca.gov/risk/chemicalDB//index.asp. The CALEPA toxicity values used in this risk assessment were obtained from the listed source and are current as of November 2013.
- ATSDR Minimal Risk Levels (MRLs) (ATSDR, 2009) address noncancer effects only, and are available on the ATSDR website at http://www.atsdr.cdc.gov/mrls.html. MRL values for intermediate exposure were used as subchronic RfD and RfC values, and MRL values for chronic exposures were used as chronic RfD and RfC values. The MRL values used in this BHHRA were obtained from that source in March 2011.
- Toxicity values remaining in current versions of HEAST (USEPA, 1997b).

Toxicity values were not available for a number of COPCs. Refer to **Table 4-1** through **4-6** for a list of these analytes. These analytes are not evaluated quantitatively in this BHHRA and the associated uncertainty is discussed in Section 6.0.

5.0 RISK CHARACTERIZATION

Risk characterization and the uncertainty analysis are the final steps in the risk assessment process. The risk characterization integrates the exposure and toxicity information generated in previous sections to quantitatively evaluate the potential health risks associated with exposure to chemicals at the Site. Risk estimates are then evaluated through a comparison to CERCLA risk management criteria. Section 5.1 describes the methodology used to calculate risks for each COPC and to sum risk estimates among COPCs, exposure pathways, and exposure media to derive cumulative receptor risks. Section 5.2 provides the risk assessment results for each of the land use scenarios evaluated in the HHRA by exposure area. Section 6.0 then identifies and discusses uncertainties in the HHRA and their potential impact on the results and conclusions of the risk assessment.

5.1 Risk Characterization Methods

Quantitative estimates of both carcinogenic and non-carcinogenic risks are calculated for each exposure scenario selected for evaluation in the exposure assessment, in accordance with USEPA (1989) guidance.

5.1.1 Risk Calculation Methodology

An estimate of the ELCR associated with exposure to each COPC in a given medium is calculated by multiplying the exposure route pathway-specific lifetime average daily dose (e.g., dermal exposure to surface soil) or lifetime average exposure concentration (e.g., inhalation of vapors) by its exposure route-specific CSF (e.g., oral CSF) or UR.

For oral and dermal exposures,

$$ELCR = \text{Lifetime Average Daily Dose (mg/kg/day)} \times CSF\ (\text{mg/kg/day})^{-1}$$

For inhalation exposures,

$$ELCR = \text{Lifetime Average Daily Exposure } (\mu g/m^3) \times UR\ (\mu g/m^3)^{-1}$$

The ELCR represents an upper bound of the probability of an individual developing cancer over a lifetime as the result of exposure to a COPC. The ELCR is calculated for each carcinogenic COPC for each medium and exposure route combination for each receptor at each exposure area. The ELCR for all COPCs in a given medium are summed to identify a route-specific total ELCR (e.g., soil ingestion) and the ELCR for all exposure routes for a given receptor/medium combination (e.g., soil ingestion and dermal contact) are summed to yield a total medium ELCR (e.g., for surface soil).

The non-cancer HQ associated with exposure to each COPC is calculated by dividing the exposure route pathway-specific average daily dose or exposure concentration by its exposure route-specific RfD or RfC.

For oral and dermal exposures,

HQ = Average Daily Dose or Exposure (mg/kg/day) / RfD (mg/kg/day)

For inhalation exposures,

HQ = Average Daily Exposure (μg/m^3) / RfC (μg/m^3)

The HQ is calculated for each COPC for each medium and exposure route combination for each receptor at each exposure area. For a given medium/receptor/age group combination (e.g., surface soil and adult outdoor worker), HQs for all COPCs are summed by route (e.g., dermal contact) to identify a medium/route HI, and the HIs for multiple exposure routes (e.g., incidental ingestion and dermal contact) are summed to identify a medium-specific total HI (e.g., for surface soil ingestion and dermal contact). Because HIs are not additive across age groups (applies to the trespasser and future resident only in this assessment), the higher HI between the two age groups is selected as the representative HI for the trespasser and child resident. An HI less than 1 indicates that non-carcinogenic toxic effects are unlikely as a result of COPC exposure. HIs greater than 1 may be indicative of a possible non-carcinogenic toxic effect. As the HI increases, so does the likelihood that adverse effects might be associated with exposure.

Risk calculations are documented in **Attachment G** (RAGS Part D Table 7s) and **Attachment H** (RAGS Part D Table 9s). The tables in **Attachment G** are grouped by soil exposure depth/exposure point (e.g. Area 1) in the following order: Surface Soil: Area 1 (G-1-G-6), Area 2 (G-7 – G-12), Area 3 (G-13 – G-18); Combined Soil (0 – 10 ft bgs): Area 1 (G-19-G-25), Area 2 (G-26 – G-32), Area 3 (G-33 – G-39) , and Combined Soil (0 – 10 ft bgs for construction/utility worker): the Sewer Line Area 1 (G-40), Sewer Line Area 2 (G-41), and Sewer Line Area 3 (G-42). **Attachment H** tables are grouped in a similar fashion. In Attachment G and in Attachment H there are tables of contents that summarize the risk calculation tables (RAGS Part D table 7s in Attachment G and the RAGS Part D table 9s in Attachment H), identifying, for each risk calculation table, the surface depth/exposure point combination, the receptor, the receptor age group (as applicable), the exposure media, and the exposure routes.

Each table in **Attachments G** documents the exposure and risk calculations for a receptor/age group (e.g. adult outdoor worker) for all exposure media (typically soil and groundwater) and exposure routes (ingestion, dermal contact, and possibly inhalation). Each of the tables document individual COPC risk (by exposure route), cumulative medium-specific risk (soil), and cumulative receptor/age group risk (soil and groundwater)

The tables in **Attachment H (**RAGS Part D table 9s) present the same calculated risk information as those in **Attachment G**, but in a slightly different structure, and also provide information beyond the simple, screening HI (it is assumed in the **Attachment G** tables that non-cancer hazards of all COPCs are additive). The Table 9s in **Attachment H** also identify the primary target organ or organ system associated with non-cancer toxicity of each COPC, and present the total HI for each identified target organ/organ system, or toxic effect type (the assumption is that the effects of COPCs with the same or similar target organ or organ system are additive). Examples of target organ/organ system or toxic effect type are liver, immune system, and developmental. The more detailed information in the Table 9s is most useful if the screening HIs are above 1, but not

dramatically so. In such cases, it may be that none of the total HIs segregated by target organ/organ system, or effect type are greater than 1.

The calculated cancer and non-cancer risks are evaluated in the context of risk management criteria established in the NCP and discussed in the preamble to the NCP (USEPA, 1990). The results of the baseline risk assessment are evaluated by comparing them to the USEPA's remedial triggers. With respect to cancer risk, USEPA identifies remediation triggers for total cancer risk "that represent an excess upper bound lifetime cancer risk to an individual of between 10^{-4} to 10^{-6} lifetime excess cancer risk." USEPA sets remediation triggers for noncancer risk "such that exposures present no appreciable risk of significant adverse effects to individuals, based on comparison of exposures to the concentration associated with reliable toxicity information such as USEPA's reference doses." For cumulative risks due to noncarcinogens, "EPA will set the remediation goals at levels for individual chemicals such that cumulative effects of multiple chemicals will not result in adverse effects." USEPA has stated that "acceptable exposure for noncarcinogens is one to which human populations, including sensitive subgroups such as pregnant women and children may be exposed without adverse effects during a lifetime or part of a lifetime, incorporating an adequate margin of safety." Given the stated remediation triggers, the results of the baseline risk assessment are evaluated in accordance with the NCP - cancer risk estimates for a site are compared to an ELCR range of 10^{-6} (one in a million) to 10^{-4} (one in ten-thousand). Total risks at or below 10^{-4} do not generally warrant a response action. Risks greater than 10^{-4} generally warrant development and evaluation of remedial alternatives. Non-cancer risks are compared to a HI value of 1, which corresponds to levels of exposure that people (including sensitive individuals) could experience without expected adverse effects.

This BHHRA was in progress when the OSWER Directive 9200.1-120 entitled "Human Health Evaluation Manual, Supplemental Guidance: Update to Standard Default Exposure Factors" was released. All of the exposure parameters had been identified in the interim deliverables for the BHHRA. Analysis has been conducted to determine what the impact might have been if exposure parameter values contained in the recent publication had been incorporated. The soil ingestion rates for the Indoor Worker (50 mg/day), Outdoor Worker (100 mg/day), Resident Child (200 mg/day), and Resident Adult (100 mg/day) used in the BHHRA are the same values that are recommended in the recent document. The Worker and Resident Adult bodyweight (70 kg used in the BHHRA and 80 kg in the recent document) results overall in a 12.5% reduction in the overall soil daily dose and associated cancer risk and noncancer hazard. For groundwater, the potable water ingestion rates for the Resident Child (1 liter/day used in the BHHRA and 0.78 liter/day in the recent document) differ by 22%. The different ingestion rate would decrease drinking water exposure and calculated risks by 22% for the Resident Child. The Resident Child bodyweight of 15 kg used in the BHHRA ids also recommended in the recent document. The potable water ingestion rate for the Resident Adult (1 2 liter/day in the BHHRA, 2.5 liter/day in the recent document) would increase the potable water intake and associated risks by 25%. However, since the bodyweight change (from 70 kg in the BHHRA to 80 kg in the recent document) is a 12.5 % increase. Since exposures are calculated using the intake rate in the numerator of an equation and the bodyweight in the denominator, the recommended changes would essentially cancel, with a net increase in riskexposure and risk of approcximately 12.5 %.

In addition, OSWER Directive 9283.1-42 entitled "Determining Groundwater Exposure Point Concentrations" was also recently released. That guidance calls for identification of groundwater EPCs by utilizing data from a small number of monitoring wells within the core of the plume. If the guidance had been employed, the groundwater EPCs for the plume may have been slightly higher. However, this would not have an impact on the conclusions, since the calculated risks for hypothetical potable use of groundwater were well above the CERCLA risk range and the noncancer hazard index was also well above 1.

5.2 Risk Characterization Results – By Soil Exposure Area Scenarios

Table 5-1 presents summaries of risks calculated for the current and future land use exposure scenarios for each exposure area (grouped, for convenience, by surface soil exposure point and receptor). **Table 5-2** presents summaries of risks calculated for the current and future land use exposure scenarios for each exposure area (grouped, for convenience, by combined soil (0-10 ft bgs) exposure point and receptor).The subsections that follow identify the calculated risks, for the current and future receptors for each exposure area and evaluate the risks relative to the NCP acceptable cancer risk range, and to a HI of 1, and identify principal contributors to risks for scenarios which have a calculated cancer risk greater than $1x10^{-4}$ and/or a HI of 1 or greater. Calculations are documented in 'RAGS Part D Table 7s and Table 9s, which are contained in **Attachments G and H**, respectively.

5.2.1 Surface Soil Area 1 Exposure Scenarios

Current and future land use receptors evaluated for Area 1 include current and future trespassers (adolescent and adult) potentially exposed to surface soil, industrial/commercial outdoor workers (potentially exposed to surface soil and soil-derived dust and ingestion at work of potable water derived from groundwater at the Site) and industrial/commercial indoor workers (potentially exposed to surface soil, ingestion at work of potable water derived from groundwater at the Site, and potential inhalation of vapors (vapor intrusion)), and hypothetical future residents (child and adult) potentially exposed to surface soil, ingestion and dermal contact with potable water derived from groundwater at the Site, and inhalation during showering. These same receptors have been evaluated for Surface Soil Area 2 Exposure Scenarios (Section 5.2.2) and Surface Soil Area 3 Exposure Scenarios (Section 5.2.3).

5.2.1.1 Current and Future Trespasser

As indicated in **Table 5-1**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 1 potentially exposed to surface soil (6×10^{-7}) is within the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.4 for the Adolescent Trespasser potentially exposed to surface soil).

5.2.1.2 Future Outdoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Outdoor Worker at Area 1 potentially exposed to surface soil and soil-derived dust ($2 X 10^{-6}$) is within the acceptable risk range and the screening

HI (0.8) is below 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}) and arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker at Area 1 Surface Soil Scenario) cancer risk (5 X 10^{4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1.

When metals in groundwater are excluded from the risk calculations, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS/Madison plume (3 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (5) is above 1. The largest contributors to cancer risk are vinyl chloride (2 X 10^{-4}) and benzene (7 X 10^{-5}) and the predominant contributors to HI are 1,2,3-trichlorobenzene (4), -1,2-DCE (1), benzene (0.9), and 1,2,4-trichlorobenzene (0.5).

5.2.1.3 Future Indoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Indoor Worker at Area 1 potentially exposed to surface soil and soil-derived dust (1 X 10^{-6}) is within the acceptable risk range and the screening HI (0.4) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}) and arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Indoor Worker at Area 1 Surface Soil Scenario) cancer risk (5 X 10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (89) is well above 1.

5.2.1.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-1**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 1 potentially exposed to surface soil (2 x 10^{-5}) is within the acceptable cancer risk range and the screening HI (11) is above 1 for the child (and equal to 1 for the adult). The predominant contributors to the child HI are vanadium (7.4), thallium (1.4), and 1,2,3-trichlorobenzene (1.1).

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS/Madison plume, and inhalation of volatiles during showering (1 x 10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water

(ingestion, dermal, and inhalation exposures) cancer risk are benzene (3.8 X 10^{-3}), 1,4-dichlorobenzene (3.1 X 10^{-3}), vinyl chloride (1.6 X 10^{-3}), 1,2-dichloroethane (7.1 X 10^{-4}), arsenic (4 X 10^{-4}), and1,1,2,2-tetrachloroethane (1.7 X 10^{-4}). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) at Area 1 Surface Soil Scenario) cancer risk (1 X 10^{-2}) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1.

5.2.2 Surface Soil Area 2 Exposure Scenarios

5.2.2.1 Current and Future Trespasser

As indicated in **Table 5-1**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 2 potentially exposed to surface soil (1 x 10^{-6}) is within the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.2 for the Adolescent Trespasser potentially exposed to surface soil).

5.2.2.2 Future Outdoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Outdoor Worker at Area 2 potentially exposed to surface soil and soil-derived dust (3 X 10^{-6}) is within the acceptable risk range and the screening HI (0.5) is below 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}) and arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker at Area 2 Surface Soil Scenario) cancer risk (5 X 10^{4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with surface soil exposures in Area 2 are negligible.

When metals in groundwater are excluded from the risk calculations, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (3 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (5) is above 1. The largest contributors to cancer risk are vinyl chloride (2 X 10^{-4}) and benzene (7 X 10^{-5}) and the predominant contributors to HI are 1,2,3-trichlorobenzene (4), -1,2-DCE (1), benzene (0.9), and 1,2,4-trichlorobenzene (0.5).

5.2.2.3 Future Indoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Indoor Worker at Area 2 potentially exposed to surface soil and soil-derived dust (1 X 10^{-6}) is within the acceptable risk range and the screening HI (0.3) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}) and arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1). **The cancer risk (7 X 10^{-7}) associated potential future indoor inhalation of vapors is within the acceptable risk range and the corresponding Hazard Index (0.1) is well below 1.**

The total receptor (Future Indoor Worker at Area 2 Surface Soil Scenario) cancer risk (5 X 10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with surface soil exposures in Area 2 are negligible.

5.2.2.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-1**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 2 potentially exposed to surface soil (4 x 10^{-5}) is within the acceptable cancer risk range and the screening HI (7) is above 1 for the child (and at 0.7, less than 1 for the adult). The predominant contributors to the child HI are vanadium (5) and thallium (2).

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS plume, and inhalation of volatiles during showering (1 x 10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water (ingestion, dermal, and inhalation exposures) cancer risk are benzene (3.8 X 10^{-3}), 1,4-dichlorobenzene (3.1 X 10^{-3}), vinyl chloride (1.6 X 10^{-3}), 1,2-dichloroethane (7.1 X 10^{-4}), arsenic (4 X 10^{-4}), and1,1,2,2-tetrachloroethane (1.7 X 10^{-4}). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) At Area 2 Surface Soil Scenario) cancer risk (1 X 10^{-2}) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1. These risks are almost completely associated with

the hypothetical future potable use of groundwater (particularly inhalation of volatiles during showering). The risks associated with surface soil exposures in Area 2 are negligible (thallium and vanadium (predominant contributors to HI) concentrations in surface soil are consistent with background conditions).

5.2.3 Surface Soil Area 3 Exposure Scenarios

5.2.3.1 Current and Future Trespasser

As indicated in **Table 5-1**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 3 Surface Soil Scenario potentially exposed to surface soil (4×10^{-7}) is within the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.1 for the Adolescent Trespasser potentially exposed to surface soil).

5.2.3.2 Future Outdoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Outdoor Worker at Area 3 potentially exposed to surface soil and soil-derived dust ($1 \text{ X } 10^{-6}$) is within the acceptable risk range and the screening HI (0.2) is below 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride ($2 \text{ X } 10^{-4}$) and arsenic ($1 \text{ X } 10^{-4}$) and benzene ($7 \text{ X } 10^{-5}$). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker in Area 3 Surface Soil Scenario) cancer risk ($5 \text{ X } 10^{-4}$) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with surface soil exposures in Area 3 are negligible.

When metals in groundwater are excluded from the risk calculations, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (3×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (5) is above 1. The largest contributors to cancer risk are vinyl chloride ($2 \text{ X } 10^{-4}$) and benzene ($7 \text{ X } 10^{-5}$) and the predominant contributors to HI are 1,2,3-trichlorobenzene (4), -1,2-DCE (1), benzene (0.9), and 1,2,4-trichlorobenzene (0.5).

5.2.3.3 Future Indoor Worker

As indicated in **Table 5-1**, cancer risk for the Future Indoor Worker at Area 3 potentially exposed to surface soil and soil-derived dust ($7 \text{ X } 10^{-7}$) is within the acceptable risk range and the screening HI (0.1) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride ($2 \text{ X } 10^{-4}$) and arsenic ($1 \text{ X } 10^{-4}$) and benzene ($7 \text{ X } 10^{-5}$). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Indoor Worker at Area 3 Surface Soil Scenario) cancer risk (5 X 10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with surface soil exposures in Area 3 are negligible.

5.2.3.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-1**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 3 potentially exposed to surface soil (9 x 10^{-6}) is within the acceptable cancer risk range and the screening HI (3) is above 1 for the child (and at 0.4, less than 1 for the adult). The predominant contributor to the child HI is vanadium (3).

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS plume, and inhalation of volatiles during showering (1 x 10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water (ingestion, dermal, and inhalation exposures) cancer risk are benzene (3.8 X 10^{-3}), 1,4-dichlorobenzene (3.1 X 10^{-3}), vinyl chloride (1.6 X 10^{-3}), 1,2-dichloroethane (7.1 X 10^{-4}), arsenic (4 X 10^{-4}), and1,1,2,2-tetrachloroethane (1.7 X 10^{-4}). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) in Area 3 Surface Soil Scenario) cancer risk (1 X 10^{-2}) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater (particularly inhalation of volatiles during showering). The risks associated with surface soil exposures in Area 3 are negligible (vanadium (predominant contributor to HI) concentrations in surface soil are consistent with background conditions).

5.2.4 Combined Soil (0 – 10 ft bgs) Area 1 Exposure Scenarios

Current and future land use receptors evaluated for Area 1 include current and future trespassers (adolescent and adult) potentially exposed to combined soil, industrial/commercial outdoor workers (potentially exposed to combined soil and soil-derived dust and ingestion at work of potable water derived from groundwater at the Site), industrial/commercial indoor workers (potentially exposed to combined soil, ingestion at work of potable water derived from groundwater at the Site, and potential inhalation of vapors (vapor intrusion)), hypothetical future residents (child and adult) potentially exposed to combined soil, ingestion and dermal contact with potable water derived from groundwater at the Site, and inhalation during showering, and

future construction/excavation workers (potentially exposed to combined soil and inhalation of soil-derived dust and to shallow groundwater in an excavation and inhalation of vapors released from an excavation).

These same receptors have been evaluated for Combined Soil Area 2 Exposure Scenarios (Section 5.2.5) and Combined Soil Area 3 Exposure Scenarios (Section 5.2.6).

5.2.4.1 Current and Future Trespasser

As indicated in **Table 5-2**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 1 potentially exposed to combined soil (1×10^{-6}) is within the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.6 for the Adolescent Trespasser potentially exposed to combined soil).

5.2.4.2 Future Outdoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Outdoor Worker at Area 1 potentially exposed to combined soil and soil-derived dust (4×10^{-6}) is within the acceptable risk range and the screening HI (1) is equal to 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2×10^{-4}) and arsenic (1×10^{-4}) and benzene (7×10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker in Area 1 Combined Soil) cancer risk (5×10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 1 are negligible.

5.2.4.3 Future Indoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Indoor Worker at Area 1 potentially exposed to combined soil and soil-derived dust (2×10^{-6}) is within the acceptable risk range and the screening HI (0.6) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2×10^{-4}), arsenic (1×10^{-4}) and benzene (7×10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Indoor Worker in Area 1 Combined Soil) cancer risk (5×10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (89) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 1 are negligible.

5.2.4.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-1**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 1 potentially exposed to combined soil (3×10^{-5}) is within the acceptable cancer risk range and the screening HI (16) is above 1 for the child (and at 1.7, above 1 for the adult). The predominant contributors to the child HI are vanadium (12) and trichloroethene (1.8).

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS plume, and inhalation of volatiles during showering (1×10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water (ingestion, dermal, and inhalation exposures) cancer risk are benzene ($3.8 \text{ X } 10^{-3}$), 1,4-dichlorobenzene ($3.1 \text{ X } 10^{-3}$), vinyl chloride ($1.6 \text{ X } 10^{-3}$), 1,2-dichloroethane ($7.1 \text{ X } 10^{-4}$), arsenic ($4 \text{ X } 10^{-4}$), and1,1,2,2-tetrachloroethane ($1.7 \text{ X } 10^{-4}$). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) in Area 1 Combined Soil Scenario) cancer risk ($1 \text{ X } 10^{-2}$) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater (particularly inhalation of volatiles during showering). The cancer risks associated with combined soil exposures in Area 1 are within the acceptable risk range and the HI for combined soil exposures is slightly above 1 (vanadium (predominant contributor to HI) concentrations in combined soil are consistent with background conditions and trichloroethene HI is slightly above 1).

5.2.4.5 Future Construction Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction Worker at Area 1 potentially exposed to combined soil and soil-derived dust ($6 \text{ X } 10^{-7}$) is below the acceptable risk range and the screening HI is equal to 1). The cancer risk associated with incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from shallow groundwater in an excavation ($1 \text{ X } 10^{-3}$) is above the acceptable risk range and the screening HI (230) is orders of magnitude above 1. Cancer risk and HI for ingestion and dermal contact with groundwater are negligible contributors to the groundwater risks. <u>Virtually all of the risks for the construction worker are associated with potential inhalation exposures (VOCs released from shallow groundwater) evaluated using a trench model (cancer risk of $1 \text{ X } 10^{-3}$ and HI = 230)</u>. Benzene is the predominant cancer risk contributor ($1 \text{ X } 10^{-3}$) and the largest contributors to the HI are benzene (140), chlorobenzene (45), xylenes (16), 1,2,4-trichlorobenzene (11), vinyl chloride (7.1), toluene (5.1), and 1,4-dichlorobenzene (1.5).

The total receptor (Future Construction Worker in Area 1 Combined Soil) cancer risk (1 X 10^{-3}) is above the acceptable risk range and the screening HI (230) is orders of magnitude above 1.

5.2.5 Combined Soil (0 – 10 ft bgs) Area 2 Exposure Scenarios

5.2.5.1 Current and Future Trespasser

As indicated in **Table 5-2**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 2 potentially exposed to combined soil (1 x 10^{-6}) is within the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.4 for the Adolescent Trespasser potentially exposed to combined soil).

5.2.5.2 Future Outdoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Outdoor Worker at Area 2 potentially exposed to combined soil and soil-derived dust (3 X 10^{-6}) is within the acceptable risk range and the screening HI (0.7) is less than 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}), arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker in Area 2 Combined Soil) cancer risk (5 X 10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 2 are negligible.

5.2.5.3 Future Indoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Indoor Worker at Area 2 potentially exposed to combined soil and soil-derived dust (1 X 10^{-6}) is within the acceptable risk range and the screening HI (0.4) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5 x 10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride (2 X 10^{-4}), arsenic (1 X 10^{-4}) and benzene (7 X 10^{-5}). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1). The cancer risk (7 X 10^{-7}) associated potential future indoor inhalation of vapors (based on indoor air data from the currently vacant building in Area 2) is within the acceptable risk range and the corresponding Hazard Index (0.1) is well below 1.

The total receptor (Future Indoor Worker in Area 2 Combined Soil) cancer risk (5 X 10^{-4}) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 2 are negligible.

5.2.5.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-2**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 2 potentially exposed to combined soil (3×10^{-5}) is within the acceptable cancer risk range and the screening HI (10) is above 1 for the child (and at 1.1, slightly above 1 for the adult). The predominant contributors to the child HI are vanadium (8.7) and thallium (1.2). The concentrations of these metals are consistent with background concentrations.

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS plume, and inhalation of volatiles during showering (1×10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water (ingestion, dermal, and inhalation exposures) cancer risk are benzene ($3.8 \text{ X } 10^{-3}$), 1,4-dichlorobenzene ($3.1 \text{ X } 10^{-3}$), vinyl chloride ($1.6 \text{ X } 10^{-3}$), 1,2-dichloroethane ($7.1 \text{ X } 10^{-4}$), arsenic ($4 \text{ X } 10^{-4}$), and1,1,2,2-tetrachloroethane ($1.7 \text{ X } 10^{-4}$). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) in Area 2 Combined Soil Scenario) cancer risk ($1 \text{ X } 10^{-2}$) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater (particularly inhalation of volatiles during showering). **The risks associated with combined soil exposures in Area 2 are negligible (vanadium and thallium (predominant contributors to HI) concentrations in surface soil are consistent with background conditions).**

5.2.5.5 Future Construction Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction Worker at Area 2 potentially exposed to combined soil and soil-derived dust ($4 \text{ X } 10^{-7}$) is below the acceptable risk range and the screening HI (0.4) is below 1). The cancer risk associated with incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from groundwater in an excavation ($5 \text{ X } 10^{-7}$) is below the acceptable risk range and the screening HI (0.1) is below 1. Cancer risk and HI for ingestion and dermal contact with groundwater and inhalation of volatiles in an excavation are negligible.

The total receptor (Future Construction Worker in Area 2 Combined Soil) cancer risk ($9 \text{ X } 10^{-7}$) is below the acceptable risk range and the screening HI (0.5) is below 1.

5.2.6 Combined Soil (0 – 10 ft bgs) Area 3 Exposure Scenarios

5.2.6.1 Current and Future Trespasser

As indicated in **Table 5-2**, total cancer risk for the Current and Future Trespasser (adolescent and adult) at Area 3 potentially exposed to combined soil (5×10^{-7}) is below the acceptable cancer risk range and the screening HI is well below 1 for each age group (higher value is 0.4 for the Adolescent Trespasser potentially exposed to combined soil).

5.2.6.2 Future Outdoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Outdoor Worker at Area 3 potentially exposed to combined soil and soil-derived dust ($2 \text{ X } 10^{-6}$) is within the acceptable risk range and the screening HI (0.7) is below 1. The cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride ($2 \text{ X } 10^{-4}$) and arsenic ($1 \text{ X } 10^{-4}$) and benzene ($7 \text{ X } 10^{-5}$). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Outdoor Worker in Area 3 Combined Soil) cancer risk ($5 \text{ X } 10^{-4}$) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 3 are negligible.

5.2.6.3 Future Indoor Worker

As indicated in **Table 5-2**, cancer risk for the Future Indoor Worker at Area 3 potentially exposed to combined soil and soil-derived dust ($1 \text{ X } 10^{-6}$) is within the acceptable risk range and the screening HI (0.4) is below 1. As was reported for the future outdoor worker, the cancer risk associated with future ingestion, at work, of potable water obtained from groundwater within the CPS plume (5×10^{-4}) is above the upper end of the acceptable risk range and the screening HI (88) is well above 1. The largest contributors to potable water ingestion cancer risk are vinyl chloride ($2 \text{ X } 10^{-4}$), arsenic ($1 \text{ X } 10^{-4}$) and benzene ($7 \text{ X } 10^{-5}$). The largest contributors to potable water ingestion HI are vanadium (40), copper (10), iron (5), thallium (8), and zinc (7) and cis-1,2-DCE (1).

The total receptor (Future Indoor Worker in Area 3 Combined Soil) cancer risk ($5 \text{ X } 10^{-4}$) is above the upper end of the acceptable risk range and the total receptor screening HI (88) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater. The risks associated with combined soil exposures in Area 3 are negligible.

5.2.6.4 Hypothetical Future On-Site Resident

As indicated in **Table 5-2**, total cancer risk for the Hypothetical Future On-Site Resident (child and adult) at Area 3 potentially exposed to combined soil (1×10^{-5}) is within the acceptable cancer risk range and the screening HI (10) is above 1 for the child (and at 1.1, slightly above 1 for the

adult). The predominant contributor to the child HI is vanadium (9). The vanadium concentrations in combined soil are consistent with background.

The cancer risk associated with hypothetical future ingestion and dermal contact with potable water obtained from groundwater within the CPS plume, and inhalation of volatiles during showering (1 x 10^{-2}) is above the upper end of the acceptable risk range and the screening HI (2725) is well above 1. The cancer risk and Hazard Index associated with inhalation of volatiles during showering represent more than 75% of the total potable water use risks, with ingestion and dermal risks contributing the remainder of the risks. The largest contributors to potable water (ingestion, dermal, and inhalation exposures) cancer risk are benzene (3.8 X 10^{-3}), 1,4-dichlorobenzene (3.1 X 10^{-3}), vinyl chloride (1.6 X 10^{-3}), 1,2-dichloroethane (7.1 X 10^{-4}), arsenic (4 X 10^{-4}), and1,1,2,2-tetrachloroethane (1.7 X 10^{-4}). The largest contributors to potable water (ingestion, dermal, and inhalation) HI are 1,2,4-trichlorobenzene (1490), vanadium (343), chlorobenzene (199), mercury (143), benzene (89), copper (85), thallium (50), zinc (48), 1,2-dichloropropane (33), iron (31), 1,2,3-trichlorobenzene(25), 1,2,4-trichlorobenzene (24), 1,2-dichloroethane (21), o-xylene (19), 1,1,2-trichloroethane (19), 1,2-dichlorobenzene (16), xylenes, total (15), naphthalene (10), toluene (9), cis 1,2-DCE (7), cadmium (7), methylene chloride (6), vinyl chloride (5), aniline (4), antimony (4), arsenic (4), aluminum (4), trans-1,2-DCE (3), ethylbenzene (3), 1,4-dichlorobenzene(2), and 1,3-dichlorobenzene (1).

The total receptor (Hypothetical Future Resident (child and adult) in Area 3 Combined Soil Scenario) cancer risk (1 X 10^{-2}) is above the upper end of the acceptable risk range and the total receptor (child) screening HI (2725) is well above 1. These risks are almost completely associated with the hypothetical future potable use of groundwater (particularly inhalation of volatiles during showering). The risks associated with combined soil exposures in Area 3 are negligible (vanadium (predominant contributor to HI) concentrations in combined soil are consistent with background conditions).

5.2.6.5 Future Construction Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction Worker at Area 3 potentially exposed to combined soil and soil-derived dust (3 X 10^{-7}) is below the acceptable risk range and the screening HI (0.3) is below 1). The cancer risk associated with incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from groundwater in an excavation (6 X 10^{-10}) is well below the acceptable risk range and the screening HI (0.00007) is orders of magnitude below 1.

The total receptor (Future Construction Worker in Area 3 Combined Soil) cancer risk (3 X 10^{-7}) is below the acceptable risk range and the screening HI (0.3) is below 1.

5.2.7 Combined Soil (0 – 10 ft bgs) Area 1 Sewer Line Exposure Scenarios

5.2.7.1 Future Construction/Utility Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction/Utility Worker at the Sewer Line at Area 1 potentially exposed to combined soil and soil-derived dust (4 X 10^{-7}) is below the acceptable risk range and the screening HI (0.4) is below 1). The cancer risk associated with

incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from groundwater in an excavation (1 X 10^{-3}) is above the acceptable risk range and the screening HI (230) is orders of magnitude above 1. Cancer risk and HI for ingestion and dermal contact with groundwater are negligible contributors to the groundwater risks. Virtually all of the risks are associated with potential inhalation exposures evaluated using a trench model. Benzene is the predominant contributor to the cancer risk. Benzene (140), chlorobenzene (45), xylenes (16), 1,2,4-trichlorobenzene (11), vinyl chloride (7.1), toluene (5.1), naphthalene (4.2), and 1,4-dichlorobenzene (1.4) are the predominant contributors to this inhalation HI.

The total receptor (Future Construction/Utility Worker at the Sewer Line at Area 1 Combined Soil) cancer risk (1 X 10^{-3}) is above the acceptable risk range and the screening HI (230) is above 1.

5.2.8 Combined Soil (0 – 10 ft bgs) Area 2 Sewer Line Exposure Scenarios

5.2.8.1 Future Construction/Utility Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction/Utility Worker at the Sewer Line at Area 2 potentially exposed to combined soil and soil-derived dust (4 X 10^{-7}) is below the acceptable risk range and the screening HI (0.4) is below 1). The cancer risk associated with incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from groundwater in an excavation (5 X 10^{-7}) is below the acceptable risk range and the screening HI (0.5) is below 1.

The total receptor (Future Construction/Utility Worker at the Sewer Line at Area 2 Combined Soil) cancer risk (8 X 10^{-7}) is below the acceptable risk range and the screening HI (0.5) is below 1.

5.2.9 Combined Soil (0 – 10 ft bgs) Area 3 Sewer Line Exposure Scenarios

5.2.9.1 Future Construction/Utility Worker

As indicated in **Table 5-2**, cancer risk for the Future Construction/Utility Worker at the Sewer Line at Area 3 potentially exposed to combined soil and soil-derived dust (4 X 10^{-7}) is below the acceptable risk range and the screening HI (0.4) is below 1). The cancer risk associated with incidental ingestion and dermal contact with shallow groundwater in an excavation and the inhalation of volatiles released from groundwater in an excavation (6 X 10^{-10}) is below the acceptable risk range and the screening HI (0.00007) is orders of magnitude below 1.

The total receptor (Future Construction/Utility Worker at the Sewer Line at Area 3 Combined Soil) cancer risk (4 X 10^{-7}) is below the acceptable risk range and the screening HI (0.4) is below 1.

6.0 UNCERTAINTY ANALYSIS

This subsection identifies and discusses uncertainties in the risk assessment. These uncertainties are identified to provide perspective on the quantitative risk estimates. Unlike some other assessments, risk assessments rely not just on measured or certain facts, but also on assumptions and estimates, and also policy decisions, in the face of limited or nonexistent data. Historically, many risk assessments have used highly conservative assumptions in the place of unavailable data, with the net result often being a substantial overestimation of potential risks. It is important, however, to evaluate the assumptions and choices made in any risk assessment to evaluate their impact on the results and conclusions.

The following types of uncertainties should be considered in any HHRA:

- uncertainties in the nature and extent of release of COPC;
- uncertainties associated with the identification of future land uses and potential receptors;
- uncertainties in estimating the frequency, duration, and magnitude of possible exposures (including the identification of representative EPCs in environmental media);
- uncertainties associated with assigning exposure parameters to a heterogeneous population that includes both men and women and young and old (e.g., BW and ingestion rates);
- uncertainties in estimating CSFs and URs and/or non-carcinogenic measures of toxicity (e.g., RfDs or RfCs); and
- uncertainties in the assumption of additivity of risks across multiple COPCs and exposure pathways.

6.1 Data Evaluation and Selection of COPCs

6.1.1 Nature and Extent of Releases to Environmental Media

The investigations of the CPS/Madison Superfund site have been comprehensive and there are representative analytical data for soil, groundwater, soil vapor, and indoor air that have been considered in the BHHRA. The investigations have included the comprehensive standard suite of analytical parameters (metals and inorganics, VOCs, SVOCs, and pesticides and PCBs).

Investigations have focused on known sources, migration pathways, and potential exposure points. The RI sampling events have provided representative spatial coverage for soil in all three exposure areas at the former CPS property (Areas 1, 2, and 3) as well shallow groundwater at the former CPS property and the CPS/Madison groundwater plume. The nature and extent of releases to environmental media has been well characterized.

The RI Report includes an evaluation of vanadium and thallium in soils at the Site. The available data indicate that concentrations in soil samples are consistent with background conditions. The risks associated with these analytes would therefore be associated with background conditions, rather than a release.

6.1.2 Selection of Data for Use in Risk Assessment

The selection of data has been completed in a manner consistent with the objectives of the BHHRA. With the exception of soils data associated with samples collected at depths greater than 10 ft bgs (inaccessible soils) and QA/QC samples that have been used in the data validation activities, the analytical data presented in the RI Report and contained within the Site database were considered for inclusion in this BHHRA. For groundwater, the most recent analytical data have generally been selected for use in the risk assessment. The selection of data for use in the BHHRA appears to be a risk-neutral activity.

6.1.3 Selection of COPCs

The selection of COPCs has been conducted in a manner consistent with USEPA guidance (USEPA, 1989) and with standard industry practice. The approach used for selection of COPCs has little impact on the results and conclusions of the risk assessment (unlikely to result in any substantial overestimation or underestimation of risks).

As requested by USEPA, in the absence of speciation analytical data for chromium, total chromium analytical data for surface soil and shallow subsurface soil have been evaluated in the COPC selection process using the residential RSL (0.29 mg/kg) for chromium (VI). The selection of chromium as a COPC is therefore based on a very conservative assumption. If the chromium (III), insoluble salts RSL (12,000 mg/kg) had been employed, chromium would not have been selected as a COPC. The history of activities at the CPS facility does not indicate any expected release of hexavalent chromium. In soil samples, total chromium concentrations ranged from 0.0081 mg/kg to 144 mg/kg. The mean and median total chromium concentrations in soil samples were 14.9 mg/kg and 18.0 mg/kg respectively.

6.2 Exposure Assessment

6.2.1 Land Uses and Receptors

The property has historically been in industrial use and it is currently not in any active use. The trespasser is the current land use receptor that has been evaluated in the BHHRA. The current and assumed future land uses are consistent with the current owner's expectations and an institutional control will be implemented to maintain Areas 1 and 2 of the property in industrial/commercial use. The BHHRA has, however, evaluated a hypothetical future residential land use scenario for Areas 1, 2, and 3 in order to provide assessment of the full range of potential land uses, to assist in determining the content of any land use restrictions that might be applied to the former CPS property, and to assist in deriving remedial action objectives, especially with respect to groundwater.

The evaluation of hypothetical future use of groundwater from the CPS/Madison plume is not based on any specific expectation that a potable water supply would be put in place within the plume – but it is based on the understanding that restoration of the groundwater resource to a condition suitable for potable use will be a requirement. The BHHRA will provide a risk component for use in the Feasibility Study.

The groundwater/surface water interaction study concluded that there was not evidence of a significant migration pathway for CPS chemicals of interest. The surface water and sediment of the brook adjacent to the CPS site provides little opportunity for any recreational activity (poor access and very shallow). No sediment data were available for a screening of human health risk. The risks associated with potential surface water and sediment exposures was not conducted in the BHHRA.

6.2.2 Estimating the Frequency, Duration, and Magnitude of Possible Exposures

The BHHRA utilized exposure parameter values (frequency of exposure, duration of exposure, skin surface areas exposed, soil and groundwater ingestion rates, etc.), obtained primarily from USEPA publications, that are generally representative of reasonable maximum exposure scenarios. However, in some instances, (such as the inhalation shower model for residential receptors and the trench model for the construction worker), the combination of exposure parameters and fate and transport estimates likely result in substantial overestimates of exposures and associated cancer risks and noncancer hazards.

There is an uncertainty associated with the magnitude of dermal exposures associated with several metals in soil. There is insufficient information available to calculate dermal exposures and dermal risks associated with aluminum, antimony, chromium, cobalt, copper, manganese, thallium, and vanadium in soil (uncertainty in absorption efficiency from soil through the skin). USEPA RAGS Part E guidance (USEPA, 2004) indicates for inorganics, the speciation of the compound is critical to the dermal absorption and there are too little data to extrapolate a reasonable default value to be applied for evaluating dermal exposure. The guidance suggests the pathway be evaluated qualitatively. Therefore, there is some underestimation of risk associated with dermal exposure to soil for these COPCs.

There are no default USEPA dermal absorption values recommended for VOCs because they would tend to be volatilized from the soil on skin. This suggests that dermal exposure for volatile soil COPCs is likely to be minimal. The absence of a quantitative evaluation of this pathway for VOCs is unlikely to have a substantial impact on the results and conclusions of the HHRA.

The vapor intrusion pathway has been evaluated using vapor intrusion screening values (from USEPA and NJDEP) for groundwater, soil vapor, and indoor air. There is one vacant building at the CPS property and the active manufacturing buildings on the Madison Industries property.

Risks have been characterized for the vapor intrusion/indoor air pathway using two different approaches. First, groundwater, sub-slab soil vapor, and indoor air (vacant on-property building)

data have been compared to NJDEP screening values. Second, sub-slab soil vapor and indoor air data have been evaluated using the USEPA Region II Vapor Intrusion Matrix Tables.

Vapor intrusion for hypothetical future buildings at the CPS and Madison Industries properties has not been quantitatively evaluated in the BHHRA. USEPA guidance indicates that management of vapor intrusion with land use restrictions or requirements for engineering controls of vapor intrusion are the most effective approach for addressing this potential future exposure pathway for buildings that might be built and occupied in the future. It is not possible to accurately evaluate potential impacts to indoor air for buildings with unknown locations, construction characteristics, and HVAC configurations.

Consumption of home-grown fruits and vegetables was not quantitatively evaluated in the BHHRA. Therefore, hypothetical future risks associated with soils for a residential scenario involving consumption of fruits and vegetables is likely underestimated in the BHHRA. It is assumed this exposure pathway will be addressed with a land use restriction that would maintain Areas 1 and 2 in industrial/commercial use and that would not allow growing of fruits and vegetables for human consumption.

Inhalation exposures for receptors related to release of soil particulates to ambient air have been evaluated for outdoor workers and construction workers and inhalation of vapors released from soil to ambient air was not evaluated quantitatively. With this migration pathway, vapors are attenuated quickly in the ambient air. It is unlikely that this exposure pathway would result in exposures or risks that approach or are greater than direct contact soil exposures (ingestion and dermal contact).

6.3 Toxicity Assessment

6.3.1 COPCs Without Toxicity Values

There are several detected parameters that were selected as COPCs because there were no RSLs available. For most of those COPCs, there are no readily available published toxicity values from Tier I, II, or III data sources. Those COPCs include, but are not limited to, for soil, 1,3-dichlorobenzene, methyl cyclohexane, p-isopropyltoluene, and t-butyl alcohol, and for groundwater 1,3-dichlorobenzene , 3-methylhexane , methyl cyclohexane , dimethylsulfide , p-isopropyltoluene , sulfur dioxide , tert butyl alcohol , and 3-nitroaniline . Obviously, if no toxicity values are available and no risks were calculated for those parameters, the HHRA would underestimate risk for those parameters.

Some toxicity values were obtained from PPRTV Document Appendices. These values were selected, but confidence in thewse values is not as great as for IRIS values or the actual PPRTVs.

6.3.2 Hexavalent Chromium

The site investigation did not include laboratory analysis of soil or groundwater samples for hexavalent chromium. In the COPC selection process, consistent with a USEPA comment on an interim HHRA deliverable, the hexavalent chromium RSLs have been used to screen total chromium (un-speciated) analytical data. Chromium was selected as a COPC in surface soil, combined soil, and in groundwater. In the BHHRA, toxicity values for chromium III have been utilized to assess chromium exposure risks.

If some portion of the measured chromium in soil and groundwater samples was the hexavalent form, the application of chromium toxicity factors may underestimate cancer risk associated with the soil and/or groundwater exposures. However, the available information indicates that this uncertainty does not have a substantial impact on the results and conclusions of the BHHRA.

The industrial soil RSL for hexavalent chromium (6.3 mg/kg) is based on a cancer risk of 1×10^{6}. The hexavalent chromium soil concentration corresponding to a noncancer HQ of 1 for industrial soil is 35,000 mg/kg. The soil EPCs for chromium (total) at the site range from 14.58 mg/kg to 46.11 mg/kg. Even if it was very conservatively assumed that all of the chromium (total) was in fact hexavalent chromium, the industrial land use cancer risks associated with the range of soil EPCs for chromium (total) would range from 2×10^{-6} to 7×10^{-6}, well below the upper end of the allowable cancer risk range. The corresponding HQs for the range of soil EPCs would be 0.0004 to 0.001 (assuming all of the chromium in soil is in the hexavalent form). The lack of analytical data for hexavalent chromium in soil is not a substantial data gap for the BHHRA.

Although the May 2014 hexavalent chromium RSL is based on the assumed carcinogenicity of hexavalent chromium via ingestion, there is not an oral CSF for hexavalent chromium in the current USEPA IRIS file.

Until recently, there has not been scientific evidence that hexavalent chromium is carcinogenic by oral or dermal routes of exposure. Hexavalent chromium has long been considered carcinogenic via inhalation exposure. A 2008 National Toxicology Program (NTP) animal study (NTP, 2008) has provided information that hexavalent chromium is carcinogenic in mice exposed via drinking water. Based on the one 2008 NTP study, the New Jersey Department of Environmental Protection (NJDEP) has calculated an oral CSF to be used in HHRAs submitted to NJDEP under their state regulatory program (NJDEP, 2009). In September 2010, the USEPA released an External Draft for Peer Review TOXICOLOGICAL REVIEW OF HEXAVALENT CHROMIUM (CAS No. 18540-29-9) In Support of Summary Information on the Integrated Risk Information System (IRIS) (USEPA, 2010d) that contains a proposal to update the IRIS file with respect to the ingestion exposure route. The proposed revision identifies hexavalent chromium as “likely to be carcinogenic in humans” by ingestion and it includes a proposed oral CSF of 0.5 (mg/kg/day)-1. The document also proposes a revised oral RfD of 0.0009 mg/kg/day (current value in IRIS is 0.003 mg/kg/day). **The external review process and final decision-making with respect to adding the proposed oral CSF and proposed oral RfD for hexavalent chromium has not yet been completed.**

In April 2014, USEPA did release Preliminary Draft Materials in advance of the June 2014 IRIS Science Meeting that will focus, in part, on the IRIS process for hexavalent chromium. Norman

Birchfield of USEPA (NCEA) indicated on April 28, 2014, that USEPA has identified a schedule for incorporation of an oral CSF for hexavalent chromium into the IRIS file within 2 years – but he indicated that schedule is obviously subject to change.

6.4 Risk Characterization

The risks have been calculated and compared to Superfund risk management criteria and benchmarks to draw conclusions concerning the Site-related risks. The procedures applied during this process are consistent with USEPA guidance and current risk assessment practice. The risk characterization procedures do not substantially overestimate or underestimate health risks for current and future land uses.

7.0 RISK ASSESSMENT CONCLUSIONS

The BHHRA has evaluated health risks for current and potential future land uses and activities and associated receptors based on the available analytical data for environmental media at the site. The BHHRA has characterized cancer risk and noncancer hazard associated with exposures to chemicals of potential concern in surface soil (0 – 2 ft bgs) and combined soil (0 – 10 ft bgs) in Areas 1, 2, and 3 of the former CPS property, in shallow groundwater in Areas 1, 2, and 3 of the former CPS property, in groundwater within the CPS/Madison plume, and in indoor air at the vacant building in Area 2. Total cancer risk and total hazard index values have been calculated for each medium for each receptor.

Consistent with USEPA risk assessment guidance, for each receptor evaluated, total cancer risks and total hazard index have been summed across all exposure media and exposure routes to generate a cumulative receptor cancer risk and a cumulative receptor hazard index for each receptor at each exposure point.

Cumulative receptor cancer risk and cumulative receptor hazard index values have been compared to the USEPA allowable cancer risk range of 10^{-6} to 10^{-4} and the hazard index limit of 1 in order to assess the overall need for remediation or management of exposures and risks based on the BHHRA. When the cumulative receptor risk and/or hazard index values are above these limits, the total cancer risk and total hazard index values for each exposure medium are compared to the same risk limits to identify which exposure media may require remediation or management of exposures and risks. Those media are to be evaluated in the Feasibility Study.

Cumulative Receptor Cancer Risk and Cumulative Receptor Hazard Index values <u>below</u> USEPA risk limits were identified for:

- the Current and Potential Future Trespasser (adolescent and adult) exposed to surface soil for Areas 1, 2, and 3,
- the Current and Potential Future Trespasser (adolescent and adult) exposed to combined soil (0 – 10 ft bgs) for Areas 1, 2, and 3,
- the Future Construction Worker exposed to combined soil (0 – 10 ft bgs) and shallow groundwater for Areas 2 and 3,
- the Future Construction/Utility Worker exposed to combined soil (0 – 10 ft bgs) and shallow groundwater for the footprint of the Sewer Line in Areas 2 and 3.

Cumulative Receptor Cancer Risk and Cumulative Receptor Hazard Index values <u>above</u> USEPA risk limits were identified for:

- the Future Outdoor Worker exposed to surface soil and consuming, in the workplace, potable water obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3)

  - only consumption in the workplace of potable water obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits.

- the Future Indoor Worker exposed to surface soil and consuming, in the workplace, potable water obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3), and indoor air (Area 2)
  - only consumption in the workplace of potable water obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits.
- the Hypothetical Future Resident exposed to surface soil and to potable water (ingestion, dermal contact, and inhalation of vapors during showering) obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3)
  - only exposure to potable water (ingestion, dermal contact, and inhalation of vapors during showering) obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits. Hazard Index above 1 for soil exposure is associated with background concentrations of metals.
- the Future Outdoor Worker exposed to combined soil (0 – 10 ft bgs) and consuming, in the workplace, potable water obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3)
  - only consumption in the workplace of potable water obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits.
- the Future Indoor Worker exposed to combined soil (0 – 10 ft bgs) and consuming, in the workplace, potable water obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3), and indoor air (Area 2)
  - only consumption in the workplace of potable water obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits.
- the Hypothetical Future Resident exposed to combined soil (0 – 10 ft bgs) and to potable water (ingestion, dermal contact, and inhalation of vapors during showering) obtained from groundwater within the CPS/Madison plume (Areas 1, 2, and 3)
  - only exposure to potable water (ingestion, dermal contact, and inhalation of vapors during showering) obtained from groundwater within the CPS/Madison plume is associated with cancer risk and hazard above USEPA limits. Hazard Index above 1 for soil exposure is associated with background concentrations of metals.
- Future Construction Worker exposed to combined soil (0 – 10 ft bgs) and shallow groundwater (incidental ingestion, dermal contact, and inhalation of vapors released from groundwater) in Area 1
  - Only inhalation of vapors released from shallow groundwater in an excavation is associated with cancer risk and hazard above USEPA limits.

- the Future Construction/Utility Worker exposed to combined soil (0 – 10 ft bgs) and shallow groundwater (incidental ingestion, dermal contact, and inhalation of vapors released from groundwater) for the footprint of the Sewer Line in Area 1,
    - Only inhalation of vapors released from shallow groundwater in an excavation is associated with cancer risk and hazard above USEPA limits.

Notes:
IASLs - Indoor Air Screening Levels
SGSLs - Soil Gas Screening Levels
na: not available (no USEPA criteria established)
Bold/Underlined results exceed relevant Vapor Intrusion Screening Level
USEPA VI Screening Levels obtained from USEPA Vapor Intrusion Screening Level (VISL)
Calculator Version 3.2, November 2013 RSL (Regional Screening Level)
NC - Non-carcinogenic
C - Carcinogenic
The soil gas samples presented in this table are sub-slab samples.

Qualifiers:
U - Not detected above MDL
J - Indicates an estimated value
E - Indicates value exceeds calibration range
B - Indicates analyte found in associated method blank
N - indicates presumptive evidence of a compound

Notes:
All concentrations mg/L unless otherwise specified
GWSL VI - USEPA Generic Vapor Intrusion
Groundwater Screening Level; Commercial Scenario
USEPA VI Screening Levels obtained from USEPA
Vapor Intrusion Screening Level (VISL) Calculator Version 3.2, November 2013 RSL
(Regional Screening Level)
mg/L - milligrams per liter
µg/l - micrograms per liter
U - not detected, value is the reporting limit
J - value is estimated
NA - not available
Bolded and underlined indicates maximum concentration greater than GWSL VI

Table 1-6
Selection of Exposure Pathways
Baseline Human Health
Risk Assessment
CPS/Madison Superfund Site
Old Bridge, New Jersey

Scenario Timeframe	Medium	Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale	Data to be Used in HHRA
Current Use	Soil	Surface Soil	Areas 1, 2, and 3 (1)	Trespasser	Adolescent / Adult	Incidental Ingestion	Quantitative	The site is currently mostly covered with pavement; however, because some soil areas are exposed and because exposure potential is highest in surface soils (vs. subsurface soils), contact with surface soil is conservatively assumed for a trespasser under current conditions. Inhalation of soil-derived particulates in ambient air is anticipated to be a "de-minimus" exposure and is not evaluated. Volatilization of VOCs from surface soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-2 ft. and pre-SRI data 0-2 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
		Combined Soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1)			Incidental Ingestion	No	There is currently no access to subsurface soil for off-site residents who may trespass on the property as their activities are limited to the ground surface.	NA
						Dermal Contact	No		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
	Groundwater	Groundwater	Wells screened within the plume			Incidental Ingestion	No	There is no current exposure to on-Site groundwater. This pathway is not evaluated.	NA
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Surface Water	Surface Water	On-site portion of Prickett's Brook			Ingestion	No	The on-site portion of the brook is dry most of the year, hence potential for exposure is limited to non-existent.	NA
						Dermal	No		
						Inhalation of Volatiles	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern (incomplete pathway). VOCs in streambed groundwater will be screened against the tapwater RSLs. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Sediment	Sediment	On-site portion of Prickett's Brook			Incidental Ingestion	No	Since the on-site portion of the brook is dry most of the year, no sediment exposures will be evaluated.	NA
						Dermal Contact	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern. VOCs in streambed groundwater were low relative to applicable criteria and hence the pathway need not be further evaluated. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		
	All	All	All	Outdoor Commercial/Industrial Worker	Adult	All	No	There are currently no outdoor commercial/industrial workers at the Site; therefore, there is no exposure to media on- or off-Site for this receptor.	NA
	All	All	All	Indoor Commercial/Industrial Worker	Adult	All	No	There are currently no indoor commercial/industrial workers at the Site; therefore, there is no exposure to media on- or off-Site for this receptor.	NA
	All	All	All	Construction Worker	Adult	All	No	A construction worker is associated with a future scenario, and thus there is no current exposure to on- or off-Site media for this receptor.	NA
	All	All	All	Utility Worker	Adult	All	No	A utility worker is associated with a future scenario, and thus there is no current exposure to on- or off-Site media for this receptor.	NA
	All	All	All	Hypothetical On-site Resident	Child/Adult	All	No	A resident is associated with a hypothetical future scenario, and thus there is no current exposure to on- or off-Site media for this receptor.	NA

Table 1-6
Selection of Exposure Pathways
Baseline Human Health
Risk Assessment
CPS/Madison Superfund Site
Old Bridge, New Jersey

Scenario Timeframe	Medium	Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale	Data to be Used in HHRA
Potential Future Use	Soil	Surface Soil	Areas 1, 2, and 3 (1)	Trespasser	Adolescent / Adult	Incidental Ingestion	No	Evaluated under a current scenario	NA
						Dermal Contact	No		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
		Combined soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1)			Incidental Ingestion	Quantitative	Future development of the Site could result in exposed ground surfaces. Additionally, future development of the Site could result in subsurface soil (soils from 0-10 ft bgs) being brought to the ground surface. Thus exposure to subsurface soils (1) is quantitatively evaluated for incidental ingestion and dermal contact. Inhalation of soil-derived particulates in ambient air is anticipated to be a "de-minimus" exposure and is not evaluated. Volatilization of VOCs from surface soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
	Groundwater	Groundwater	Wells screened within the plume			Incidental Ingestion	No	Under future use, the trespasser is not anticipated to be exposed to potable groundwater. This pathway is not evaluated.	NA
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Surface Water	Surface Water	On-site portion of Prickett's Brook			Ingestion	No	The on-site portion of the brook is dry most of the year, hence potential for exposure is limited to non-existent.	NA
						Dermal	No		
						Inhalation of Volatiles	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern (incomplete pathway). VOCs in streambed groundwater will be screened against the tapwater RSLs. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Sediment	Sediment	On-site portion of Prickett's Brook			Incidental Ingestion	No	Since the on-site portion of the brook is dry most of the year, no sediment exposures will be evaluated.	NA
						Dermal Contact	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern. VOCs in streambed groundwater were low relative to applicable criteria and hence the pathway need not be further evaluated. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		
	Soil	Surface Soil	Areas 1, 2, and 3 (1)	Outdoor Commercial/Industrial Worker (3)	Adult	Incidental Ingestion	Quantitative	Potential exposure to surface soils are evaluated for a worker under future conditions, assuming the site is used in the future. Volatilization of VOCs from surface soils to overlying ambient air is anticipated to be minimal or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-2 ft.and pre-SRI data 0-2 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	Quantitative		
						Inhalation of Volatiles	No		
		Combined soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1)			Incidental Ingestion	Quantitative	Under future conditions it is assumed that exposure could occur as subsurface soils can be brought to the surface should the site be redeveloped. Volatilization of VOCs from subsurface soils to overlying ambient air is anticipated to be minimal or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	Quantitative		
						Inhalation of Volatiles	No		
	Groundwater	Groundwater	Wells screened within the plume			Incidental Ingestion	Quantitative	It is conservatively assumed that the on-property groundwater could be used as a potable resource. This evaluation assumes that an outdoor worker comes inside to drink potable water. No activities that would result in dermal contact with or inhalation of volatiles from the groundwater are anticipated	Analytical data from monitoring wells within the CPS Plume.
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Surface Water	Surface Water	On-site portion of Prickett's Brook			Ingestion	No	The on-site portion of the brook is dry most of the year, hence potential for exposure is limited to non-existent.	NA
						Dermal	No		
						Inhalation of Volatiles	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern. VOCs in streambed groundwater were low relative to applicable criteria and hence it was determined that the pathway need not be further evaluated. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Sediment	Sediment	On-site portion of Prickett's Brook			Incidental Ingestion	No	Since the on-site portion of the brook is dry most of the year, sediment exposures will not be evaluated.	NA
						Dermal Contact	No		
			Off-site portion of Prickett's Brook and Prickett's Pond			Incidental Ingestion	No	The Groundwater/Surface Water Interaction Evaluation concluded that surface water and sediment are not media of concern (incomplete pathway). VOCs in streambed groundwater were low relative to applicable criteria and hence the pathway need not be further evaluated. Metals are not considered COPC in media other than groundwater, per the AOC/SOW.	NA
						Dermal Contact	No		

Table 1-6
Selection of Exposure Pathways
Baseline Human Health
Risk Assessment
CPS/Madison Superfund Site
Old Bridge, New Jersey

Scenario Timeframe	Medium	Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale	Data to be Used in HHRA
Potential Future Use (cont.)	Soil	Surface Soil	Areas 1, 2, and 3 (1)	Indoor Commercial/Industrial Worker (3)	Adult	Incidental Ingestion	Quantitative	An indoor worker is assumed to spend most of his/her time indoors (i.e., an office worker), however, per USEPA guidance, some exposure to soil is assumed (3). Inhalation of soil-derived particulates in ambient air is anticipated to be a "de-minimus" exposure and is not evaluated. Volatilization of VOCs from surface soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-2 ft. and pre-SRI data 0-2 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
		Combined soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1)			Incidental Ingestion	Quantitative	An indoor worker is assumed to spend most of his/her time indoors (i.e., an office worker), however, per USEPA guidance, some exposure to soil is assumed (3). Volatilization of VOCs from surface soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
	Groundwater	Groundwater	Wells and/or well screened within the plume			Incidental Ingestion	Quantitative	It is conservatively assumed that on-property groundwater could be used as a potable resource. No activities that would result in dermal contact with or inhalation of volatiles from the groundwater are anticipated.	Analytical data from monitoring wells within the CPS Plume.
						Dermal Contact	No		
						Inhalation of Volatiles	No		
	Indoor Air	Indoor Air	On-site Area 2			Inhalation of Volatiles	Qualitative	Although the vapor intrusion evaluation determined that the vapor intrusion pathway was incomplete, an evaluation of exposure to indoor air was performed to document risks associated with this route of exposure.	Recent indoor air data.
	Soil	Combined soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1) and Sewer Line Exposure Area	Construction Worker/ Utility Worker	Adult	Incidental Ingestion	Quantitative	Workers may come into contact with constituents detected in soil in an excavation scenario.	Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft and Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft within the Sewer Line Exposure Area.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	Quantitative		
						Inhalation of Volatiles	Quantitative		
	Groundwater	Groundwater (1)	Areas 1, 2, and 3 (1)			Incidental Ingestion	Quantitative	Workers may come into contact with constituents detected in groundwater in an excavation scenario.	Most recent (2011) shallow on-site groundwater data from contaminated zone.
						Dermal Contact	Quantitative		
						Inhalation of Volatiles	Quantitative		
	Soil	Surface Soil	Areas 1, 2, and 3 (1)	Hypothetical On-site Resident	Child/Adult	Incidental Ingestion	Quantitative	Potential exposure to surface and subsurface soils are evaluated for a hypothetical resident, in the very unlikely scenario that the site is redeveloped for residential use. This scenario is highly unrealistic and is evaluated for the purpose of determining the need for institutional controls and/or further remediation. Inhalation of soil-derived particulates in ambient air is anticipated to be a "de-minimus" exposure and is not evaluated. Volatilization of VOCs from soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-2 ft. and pre-SRI data 0-2 ft. Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
	Soil	Combined soil (0 - 10 ft bgs)	Areas 1, 2, and 3 (1)		Child/Adult	Incidental Ingestion	Quantitative	Potential exposure to surface and subsurface soils are evaluated for a hypothetical resident, in the very unlikely scenario that the site is redeveloped for residential use. This scenario is highly unrealistic and is evaluated for the purpose of determining the need for institutional controls and/or further remediation. Inhalation of soil-derived particulates in ambient air is anticipated to be a "de-minimus" exposure and is not evaluated. Volatilization of VOCs from soils to overlying ambient air is anticipated to be small or not a complete pathway and thus not evaluated.	Recent (SRI) soil data 0-2 ft. and pre-SRI data 0-2 ft. Recent (SRI) soil data 0-10 ft. and pre-SRI data 0-10 ft.
						Dermal Contact	Quantitative		
						Inhalation of Particulates	No		
						Inhalation of Volatiles	No		
	Groundwater	Groundwater (2*)	Wells and/or well screened within the plume			Intentional Ingestion	Quantitative	On-site groundwater within the contaminated zone would be used for potable use. This scenario is highly unlikely. It is evaluated because site groundwater is within a drinking water source area and also to assist in guiding further cleanup (remedial goals).	Analytical data from monitoring wells within the CPS Plume.
						Dermal Contact	Quantitative		
						Inhalation of Volatiles (showering)	Quantitative		

Notes:
1.Three soil exposure points/areas will be evaluated: the on-site main plant area has been divided into Areas 1 (former tank farm) and 2 (former plant), and on-site side-lot is Area 3. Soil exposures beyond the property boundary are not evaluated as soil contamination attributable to CPS was not found to extend beyond the former CPS property boundary. Consistent with that specified in the USEPA Scope of Work, dated October 2005, this risk assessment addresses two operable units (OU): OU1, which pertains to groundwater and includes both CPS-related VOC releases and Madison-related metals releases and OU2, which pertains to soils that act as groundwater sources and contact hazards on the CPS property. This risk assessment does not address OU3 (consistent with that stated in the 2005 USEPA SOW), which pertains to soils that act as groundwater sources and contact hazards on the Madison property. Metals in soil sourced from the Madison release(s), which are found on the former CPS parcel will be addressed to be able to assess total site risk for the CPS property.
2. The risk assessment for groundwater will include compounds associated with the former CPS VOC release, the Madison Metals release and the EPLC VOC release. The contaminant plumes from these sites are co-mingled; therefore, inclusion of these constituents is necessary for addressing cumulative risk. The Hercules TBA plume will not be addressed, as the Hercules plume is not co-mingled with the CPS plume (except in a very small area downgradient near Prickett's Pond).
3. Exposure pathways are based on USEPA's Supplemental Guidance For Developing Soil Screening Levels For Superfund Sites. Solid Waste and Emergency Response. OSWER 9355.4-24. December 2002.

(1) Minimum or maximum concentration detected in data set. Samples included in data set are identified in Attachment A.
(2) The concentration used for screening is the maximum detected concentration for all analytes except for lead, which was screened using the mean lead concentration.
(3) Background concentrations were not included in the COPC screening.
(4) Values are the Regional Screening Levels (RSLs) obtained from USEPA November 2013.
Values used for screening are the residential soil RSLs for the lesser of cancer risks equal to 1E-06 or non-cancer risks equal to a hazard index of 0.1.
RSL for xylenes used for m+p-xylene.
RSL for pyrene used for phenanthrene, acenaphthylene, benzo(ghi)perylene.
RSL for chromium (VI) used for chromium.
RSL for Vanadium and compounds used for vanadium.
n - RSL is based on a non-cancer hazard quotient of 0.1
c - RSL is based on an excess lifetime cancer risk of 1 in 1 million
c* - where n RSL < 100X c RSL.
c** - where n RSL < 10 x c RSL
ns - RSL is based on a non-cancer hazard quotient of 0.1; concentration may exceed Csat
R - RBA applied
(5) There are no Applicable or Relevant and Appropriate Requirements / To Be Considered (ARAR/TBC) for soil.
(6) Analyte is selected as a COPC if the concentration used for screening exceeds the RSL or if no screening value is available.
ASL - Concentration used for screening is greater than the screening toxicity value; the analyte was selected as a COPC.
BSL - Concentration used for screening is less than the screening toxicity value; the analyte was not selected as a COPC.
NSL - No screening level available; the anlayte was selected as a COPC.
FOD - Analyte detected in less than 5% of the samples.
E - Compound is an essential nutrient.

mg/Kg - milligrams per kilogram.
COPC - Chemical of potential concern.
J - Value is estimated.
RBA - relative bioavailability factor

(1) Minimum or maximum concentration detected in data set. Samples included in data set are identified in Attachment A.
(2) The concentration used for screening is the maximum detected concentration for all analytes except for lead, which was screened using the mean lead concentration.
(3) Background concentrations were not included in the COPC screening.
(4) Values are the Regional Screening Levels (RSLs) obtained from USEPA November 2013.
Values used for screening are the residential soil RSLs for the lesser of cancer risks equal to 1E-06 or non-cancer risks equal to a hazard index of 0.1.
RSL for xylenes used for m+p-xylene.
RSL for pyrene used for phenanthrene, acenaphthylene, benzo(ghi)perylene.
RSL for chromium (VI) used for chromium.
RSL for Vanadium and compounds used for vanadium.
n - RSL is based on a non-cancer hazard quotient of 0.1
c - RSL is based on an excess lifetime cancer risk of 1 in 1 million
c* - where n RSL < 100X c RSL.
c** - where nSL < 10 x cSL
ns - RSL is based on a non-cancer hazard quotient of 0.1; concentration may exceed Csat
R - RBA applied
(5) There are no Applicable or Relevant and Appropriate Requirements / To Be Considered (ARAR/TBC) for soil.
(6) Analyte is selected as a COPC if the concentration used for screening exceeds the RSL or if no screening value is available.
ASL - Concentration used for screening is greater than the screening toxicity value; the analyte was selected as a COPC.
BSL - Concentration used for screening is less than the screening toxicity value; the analyte was not selected as a COPC.
NSL - No screening level available; the anlayte was selected as a COPC.
FOD - Analyte detected in less than 5% of the samples.
E - Compound is an essential nutrient.

mg/Kg - milligrams per kilogram.
COPC - Chemical of potential concern.
J - Value is estimated.
RBA - relative bioavailability factor

Values used for screening are the residential soil RSLs for the lesser of cancer risks equal to 1E-06 or non-cancer risks equal to a hazard index of 0.1.
RSL for xylenes used for m+p-xylene.
RSL for pyrene used for phenanthrene, acenaphthylene, benzo(ghi)perylene.
RSL for chromium (VI) used for chromium.
RSL for Vanadium and compounds used for vanadium.
n - RSL is based on a non-cancer hazard quotient of 0.1
c - RSL is based on an excess lifetime cancer risk of 1 in 1 million
c* - where n RSL < 100X c RSL.
c** - where nSL < 10 x cSL
ns - RSL is based on a non-cancer hazard quotient of 0.1; concentration may exceed Csat
R - RBA applied
(5) There are no Applicable or Relevant and Appropriate Requirements / To Be Considered (ARAR/TBC) for soil.
(6) Analyte is selected as a COPC if the concentration used for screening exceeds the RSL or if no screening value is available.
ASL - Concentration used for screening is greater than the screening toxicity value; the analyte was selected as a COPC.
BSL - Concentration used for screening is less than the screening toxicity value; the analyte was not selected as a COPC.
NSL - No screening level available; the anlayte was selected as a COPC.
FOD - Analyte detected in less than 5% of the samples.
E - Compound is an essential nutrient.

mg/Kg - milligrams per kilogram.
COPC - Chemical of potential concern.
J - Value is estimated.
RBA - relative bioavailability factor

(1) Minimum or maximum concentration detected in data set. Samples included in data set are identified in Attachment A.
(2) The concentration used for screening is the maximum detected concentration, except for lead which uses the mean.
(3) Background concentrations were not included in the COPC screening.
(4) Values are the Regional Screening Levels (RSLs) obtained from USEPA November 2013
Values used for screening are the tapwater RSLs for the lesser of cancer risks equal to 1E-06 or non-cancer risks equal to a hazard index of 0.1.
RSL for xylenes used for m+p-xylene.
RSL for pyrene used for phenanthrene and acenaphthylene
RSL for chromium (III) used for chromium.
RSL for Endosulfan used for Endosulfan II
RSL for vanadium and compounds used for vanadium.
n - RSL is based on a non-cancer hazard quotient of 0.1
c - RSL is based on an excess lifetime cancer risk of 1 in 1 million
c* - where n RSL < 100X c RSL.
c** - where nSL < 10 x cSL
L - Refer to the RSL User's Guide for lead.
(5) The Applicable or Relevant and Appropriate Requirements / To Be Considered (ARAR/TBC) groundwater values for this HHRA
are the USEPA Maximum Contaminant Levels (MCLs). USEPA MCLs or Treatment Technique (TT) Action Levels are presented in this column.
(6) Analyte is selected as a COPC if the concentration used for screening exceeds the RSL or if no screening value is available.
ASL - Concentration used for screening is greater than the screening toxicity value; the analyte was selected as a COPC.
BSL - Concentration used for screening is less than the screening toxicity value; the analyte was not selected as a COPC.
NSL - No screening level available; the anlayte was selected as a COPC.
FOD - Analyte detected in less than 5% of the samples; analyte not selected as a COPC.
E - Compound is an essential nutrient; analyte not selected as a COPC.
mg/L - milligrams per liter
COPC - Chemical of potential concern.
J - Value is estimated.

COPC - CHEMICAL OF POTENTIAL CONCERN

Prepared by: KMW 11/14/13
Checked by: LCG 11/21/13
Revised by: LCG 4/30/14
Checked by: KMW 04/30/14

Notes:
1 "Surface Water" COPCs were selected by screening groundwater discharging to surface water against The United States Environmental Protection Agency Regional Screening Levels for tapwater (adjusted)
2 Identified as a COPC based on both VOC and SVOC results.

N - Normal Distribution
[a] 95% KM (t) UCL
[b] 95 KM (% Bootstrap)
[c] 95% Student's-t UCL

G - Gamma Distribution
[d] 95% GROS (Approximate Gamma) UCL
[e] 95% Approximate Gamma KM UCL
[f] 95% Adjusted Gamma KM UCL
[g] 95% GROS Adjusted Gamma UCL

LG- Lognormal Distribution
[h] 95% KM (Chebyshev) UCL Non-Parametric
[i] 99% KM (Chebyshev) UCL Non-Parametric

NP - Non-Parametric Distribution
[j] 99% KM (Chebyshev) UCL
[k] 97.5% KM (Chebyshev) UCL

NC - Not Calculated
[l] Insufficient data to calculate meaninful statistics; no UCL calculated

(4) The maximum detected concentration is used as the EPC because it is lower than the calculated 95% UCL, or no 95% UCL is calculated.
(5) The 95% UCL is used as the EPC because the calculated 95% UCL is less than the maximum detected concentration.

EPC - Exposure Point Concentration
UCL - Upper Confidence Limit on the arithmetic mean
J - Value is estimated.

Notes:
(1) Chemicals of potential concern (COPCs) are identified in Table 2-1
(2) Notes indicate distribution type and specific UCL selected.
(3) 95% UCL is calculated using ProUCL software (Version 5.0); calculation presented in Attachment B.

Notes:
(1) Chemicals of potential concern (COPCs) are identified in Table 2-1.
(2) The arithmetic mean was calculated using 1/2 the laboratory reporting limit for non-detects.
(3) There were too few data points to calculate a 95% UCL.
(4) The maximum detected concentration is used as the EPC because it is lower than the calculated 95% UCL, or no 95% UCL is calculated.

Table 3-8
Exposure Point Concentration - Groundwater within CPS Plume
Baseline Human Health Risk Assessment
CPS Madison
Old Bridge, New Jersey

CAS Number	Chemical of Potential Concern (1)	Units	Arithmetic Mean (2)	95% UCL (3)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						EPC	Units	Statistic	Rationale

Notes:
(1) Chemicals of potential concern (COPCs) are identified in Table 2-4.
(2) The arithmetic mean was calculated using 1/2 the laboratory reporting limit for non-detects.
(3) 95% UCL is calculated using ProUCL software (Version 5.0); calculation presented in Attachment F.
(4) The maximum detected concentration is used as the EPC because it is lower than the calculated 95% UCL, or no 95% UCL is calculated.
(5) The 95% UCL is used as the EPC because the calculated 95% UCL is less than the maximum detected concentration.
(6) Antimony statistics and EPC are based on dissolved results.

Prepared By: KMW 11/13/2013
Checked By: BJR 11/21/2013
Revised by: KMW 5/16/14
Checked By: MJM 5/20/14
Prepared By: LCG 4/1/2015
Checked By: LM 4/2/2015

N - Normal Distribution
[a] 95% KM (% Bootstrap) UCL
[b] 95% KM (t) UCL

G - Gamma Distribution
[c] 95% Adjusted Gamma UCL
[d] 95% GROS Approximate Gamma UCL
[e] 95% GROS Adjusted Gamma UCL
[f] 95% Approximate Gamma UCL

LG - Lognormal Distribution
[g] 95% KM (Chebyshev) UCL Non-Parametric
[h] 95% KM (BCA) UCL Non-Parametric
[i] 99% Chebyshev (Mean Sd) UCL Non-Parametric
[j] 99% KM Chebyshev UCL Non-Parametric
[k] 97.5% KM Chebyshev UCL Non-Parametric

NP - Non-Parametric Distribution
[l] 95% KM (Chebyshev) UCL
[m] 95% KM (BCA) UCL
[m*] 95% KM (BCA) UCL suggested, but no UCL calculated.
[n] 99% KM Chebyshev UCL
[o] 97.5% KM Chebyshev UCL
[p] 95% Chebyshev (Mean, SD) UCL

NC - Not Calculated; insufficient data to calculate meaninful statistics and no UCL calculated.

EPC - Exposure Point Concentration
UCL - Upper Confidence Limit on the arithmetic mean
J - Value is estimated.
mg/L - milligrams per liter

Notes:
(1) Chemicals of potential concern (COPCs) are identified in Table 2-4.
(2) Maximum detected concentrations were used as EPCs in lieu of 95% UCLs.
(3) The maximum detected concentration is used as the EPC because it is lower than the calculated 95% UCL, or no 95% UCL is calculated

Prepared By: KMW 11/13/2013
Checked By: BJR 11/18/2013
Revised By: KMW 5/16/14
Checked By: MJM 5/20/14

EPC - Exposure Point Concentration
UCL - Upper Confidence Limit on the arithmetic mean
NA - Analyte not analyzed in the associated dataset
NC - Not calculated
ND - Analyte not detected in the associated dataset
mg/L - milligrams per liter

USEPA, 2004. "Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.
USEPA, 2006. Implementation of the Cancer Guidelines and Accompanying Supplemental Guidance - Science Policy Council Cancer Guidelines Implementation Workgroup Communication II: Performing Risk Assessments that include Carcinogens Described in the Supplemental Guidance as having a Mutagenic Mode of Action. June 14.
USEPA, 2011. "Exposure Factors Handbook: 2011 Edition"; Office of Research and Development; EPA-600/R-090/052F; Washington, D.C.; September
USEPA, 2012. "Recommendation for Default Value for Relative Bioavailability of Arsenic in Soil." OSWER 9200.1-113. December

[a] - USEPA recommended default relative bioavailablity of arsenic in soil is 60% for oral exposure pathways.
[b] In accordance with the EPA Memorandum: "Implementation of the Cancer Guidelines and Accompanying Supplemental Guidance" - the risks for mutagenic carcinogens will be calculated by multiplying the EPA-published slope factor by generic age-dependant adjustment factors (ADAFs) as follows:
Residential Children (<6 yrs of age): ADAF of 5.3 calculated as an age-weighted ADAF for children 0<2 (ADAF=10) and children 2<6 (ADAF=3), as follows: [(2 yrs x 10) + (3 yrs x 4)] / 6 yrs = 5.3.
Tresspasser Older Children/ Adolescents (Age 12 - <18); ADAF of 2.33 calculated as an age-weighted ADAF for olderchilden 12 - <18 (ADAF= 2.3), as follows: [(4 yrs x 3) + (2 yrs x 1)] / 6 yrs = 2.3.
[c] - Professional judgment.
[d] - Average of mean body weights for males and females ages 12 to 18.
[e] - Weighted average of mean values for (head, hands, forearms, and lower legs) for males and females ages 12 to 18 or 18 to 30.
[f] - Weighted average of mean body weights for males and females ages 12 to 18 or 18 to 30.
[g] - Uses the commercial/industrial PEF and assumes a ten-fold agitation factor

NA - Not Applicable
kg - kilograms
cm^2 - square centimeters
m^3 - cubic meters
mg - milligrams
yr - year
ug - micrograms
hr - hour
TBC - to be calculated
UCL - upper confidence limit

Prepared by: LCG 4/9/2015
Checked by: MJM 4/10/2015

Notes:
(1) Chemicals of potential concern (COPCs) are identified in Table 2-4.
(2) Groundwater COPCs identified as volatiles (i.e., listed in the Vapor Intrusion Screening Level (VISL) calculator) are presented herein.
(3) Groundwater EPCs are presented in Table 3-8.
(4) For all parameters except radon, H, D_a, and D_l were obtained from the USEPA VISL Caclculator Version 3.2, November 2013 RSLs (Regional Screening Level)
(5) Fraction volatilized calculated using the equation below as presented in McKone, 1987.

$$f_{species} = \frac{f_{radon} \times [(2.5/D_l{}^{\wedge 2/3}) + (RT/D_a{}^{\wedge 2/3} \times H)]_{radon}}{[(2.5/D_l{}^{\wedge 2/3)} + (RT/D_a{}^{\wedge 2/3} \times H)]_{species}}$$

Where:

f_{radon} = 0.63 during showers in Pritchard and Gesell (1981) as cited by Andelman (1990)
D_l = Diffusivity in Water
D_a = Diffusivity in Air
R = Universal Gas Constant (8.21E-5 atm-m^3/mol-K)
T = Temperature (300.15 K)
H = Henry's Law Constant
H, D_a, and D_l for radon were obtained from McKone, 1987.

(6) Air EPCs calcualted using the equations presented below:

$$\text{Ca max (mg/m}^3) = Cw \times f \times Fw \times t1 \times 1/Va$$

$$EPC = (((Camax/2) \times t1) + (Camax \times t2))/(t1+t2)$$

Where:

Parameter	Definition	Values Adult		Values Child	
T	Temperature	300.15	K	300.15	K
Fw	Shower Water Flow Rate	1000	L/hr	1000	L/hr
t1	Time Showering	0.25	hours	0.45	hours
t2	Time in Bathroom After Showering	0.33	hours	0.55	hours
Va	Bathroom Air Volume	6	m3	6	m3
f	Fraction Volatilized	Chem-specific	Unitless	Chem-specific	Unitless

Notes:

Prepared By: KMW 11/14/2013
Checked By: BJR 11/21/2013
Revised By: KMW 5/15/14
Checked by: MJM 5/20/14
Revised By: LCG 4/10/2015
Checked by: MJM 4/10/2015

In accordance with OSWER 9285.7-53, slope factors are identified from the following heirarchy of sources:

Tier 1:

IRIS = Integrated Risk Information System: Obtained from: http://www.epa.gov/IRIS/

Tier 2:

PPRTV = Preliminary Peer-Reviewed Toxicity Value: Obtained from: http://hhpprtv.ornl.gov/

Tier 3:

HEAST= Health Effects Assessment Summary Tables Obtained from: USEPA Solid Waste and Emergency Response, FY 1997 Update. EPA-540-R-97-036. July 1997.

MRL = Minimum Risk Level (ATSDR: chronic MRLs): Obtained from: http://www.atsdr.cdc.gov/mrls/index.asp

CalEPA = California Environmental Protection Agency Toxicity Criteria Database Obtained from: http://www.oehha.ca.gov/risk/chemicalDB/

NCEA = National Center for Environmental Assessment

(1) Values obtained from RAGS Volume 1 (Part E, Supplemental Guidance for Dermal Risk Assessment, Final) (USEPA, 2004)
Per this guidance, a value of 100% is used for analytes without published values.

(2) Adjusted Dermal SF = Oral SF / Oral to Dermal Adjustment Factor. Per RAGS Part E (USEPA, 2004), adjustments are only performed for chemicals that have an oral absorption efficiency of less than 50%.

[a] - Slope Factor for Benzo(a)Pyrene used for other carcinogenic PAHs, adjusted by Relative Potency Factors of 1.0 [benzo(a)pyrene,dibenz(a,h)anthracene]; 0.1 [benzo(a)anthracene, benzo(b)flouoranthene, indeno(1,2,3-c,d)pyrene].

[b] - Slope factors are developed in accordance with the USEPA Memorandum: "Implementation of the Cancer Guidelines and Accompanying Supplemental Guidance - Science Policy Council Cancer Guidelines Implementation Workgroup Communication II: Performing Risk Assessments that include Carcinogens Described in the Supplemental Guidance as having a Mutagenic Mode of Action (June 14, 2006)
USThe EPA-published slope factor will be multiplied by generic age-dependant adjustment factors (ADAFs) as follows:
Young children (<6 yrs of age): ADAF of 5.3 calculated as an age-weighted ADAF for children 0<2 (ADAF=10) and children 2<6 (ADAF=3), as follows: [(2 yrs x 10) + (3 yrs x 4)] / 6 yrs = 5.3
Older children (6 < 16 yrs of age): ADAF of 3 is the applicable value for this age range.
Adults (>16 yrs of age): ADAF of 1 is the applicable value for this age range.
Older Children/Adults (Age >6 - <30): ADAF of 1.8 calculated as an age-weighted ADAF for older children >6 - <16 (ADAF=3) and adults >16 (ADAF=1), as follows: [(10 yrs x 3) + (14 yrs x 1)] / 24 yrs = 1.8

The ADAF is only applied to the trichloroethylene kidney slope factor; Refer to Table 4-3 for these slope factors.

Weight of Evidence:
- A - Human carcinogen
- B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans
- C - Possible human carcinogen
- D - Not classifiable as a human carcinogen
- B1 - Probable human carcinogen - indicates that limited human data are available

kg = kilogram
mg = milligram
NA = not listed in hierarchy sources
ND = no data available

Chemical of Potential Concern	Unit Risk		Weight of Evidence/ Cancer Guideline Description	Unit Risk: Inhalation Cancer Slope Factor	
	Value	Units		Source	Date Verified

Notes:

In accordance with OSWER 9285.7-53, unit risk values are identified from the following heirarchy of sources:
Tier 1:
IRIS = Integrated Risk Information System:
Tier 2:
PPRTV = Preliminary Peer-Reviewed Toxicity Value:
Tier 3:
HEAST= Health Effects Assessment Summary Tables
MRL = Minimum Risk Level (ATSDR: chronic MRLs):
CalEPA = California Environmental Protection Agency Toxicity Criteria Database
PPRTV SL = Preliminary Peer-Reviewed Toxicity Value Screening Level

Weight of Evidence:
A - Human carcinogen
B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans
C - Possible human carcinogen
D - Not classifiable as a human carcinogen
NE - Carcinogenicity not evaluated by EPA

Nickel has been evaluated as Nickel soulble salts and is not evaluated by EPA for human carcinogenicity.

Surrogate (1) - Value for total xylenes used as a surrogate

	Unadjusted Slope Factors				Adjusted Slope Factors			
Units:	$(mg/kg/d)^{-1}$	$(mg/kg/d)^{-1}$	$(mg/kg/d)^{-1}$	-	$(mg/kg/d)^{-1}$	$(mg/kg/d)^{-1}$	$(mg/kg/d)^{-1}$	(mg/kg/d)-1
Age group	Kidney unadjusted lifetime slope factor (p 5-144 [Table 5-40])	NHL+ liver lifetime slope factor	Kidney+NHL+ liver unadjusted lifetime slope factor (p 5-143 [5.2.2.3])	Kidney cancer default ADAF	Kidney adjusted lifetime slope factor (p 5-144 [Table 5-40])	NHL+ liver lifetime slope factor	Kidney+NHL+ liver adjusted lifetime slope factor using Kidney cancer ADAF	**Final Slope Factor by Age**
Birth to <2 years	9.3E-03	3.7E-02	4.6E-02	10	9.3E-02	3.7E-02	1.3E-01	**1.3E-01**
2 to <6 years	9.3E-03	3.7E-02	4.6E-02	3	2.8E-02	3.7E-02	6.5E-02	**6.5E-02**
6 to <16 years	9.3E-03	3.7E-02	4.6E-02	3	2.8E-02	3.7E-02	6.5E-02	**6.5E-02**
16 to 30	9.3E-03	3.7E-02	4.6E-02	1	9.3E-03	3.7E-02	4.6E-02	**4.6E-02**
30 to 70*	9.3E-03	3.7E-02	4.6E-02	1	9.3E-03	3.7E-02	4.6E-02	**4.6E-02**
Weighted Slope Factors to be used in the HHRA:								
Age Group								
0 to 6	9.3E-03	3.7E-02	4.6E-02	5.3	4.9E-02	3.7E-02	8.6E-02	**8.6E-02**
12 to 18	9.3E-03	3.7E-02	4.6E-02	2.3	2.1E-02	3.7E-02	5.8E-02	**5.8E-02**

Notes:
Weighted slope factors calculated by calculating a weighted average ADAF and multiplying the weighted average ADAF by the kidney cancer unadjusted slope factor.
For example: For 0 to 6 years of age: = [(2 years x 10) + (4 years x 3)]/6 = 5.3

(mg/kg/d)-1 - the inverse of miligrams per kilogram per day

Table 4-5
Non-Cancer Toxicity Data - Oral/Dermal
Baseline Human Health Risk Assessment
CPS/Madison Superfund Site
Old Bridge, New Jersey

Chemical of Potential Concern	Chronic/ Subchronic	Oral RfD		Oral Absorption Efficiency for Dermal (1)	Adjusted Dermal RfD (2)		Primary Target Organ or System / Critical Effect	Combined Uncertainty/Modifying Factors	RfD: Target Organ(s)	
		Value	Units		Value	Units			Source	Date Verified

Notes:
In accordance with OSWER 9285.7-53, chronic RfDs are identified from the following heirarchy of sources:
Tier 1:
IRIS = Integrated Risk Information System: Obtained from: http://www.epa.gov/IRIS/
Tier 2:
PPRTV = Preliminary Peer-Reviewed Toxicity Value: Obtained from: http://hhpprtv.ornl.gov/
Tier 3:
HEAST= Health Effects Assessment Summary Tables Obtained from: USEPA Solid Waste and Emergency Response, FY 1997 Update. EPA-540-R-97-036. July 1997.
MRL = Minimum Risk Level (ATSDR: chronic MRLs):
PPRTV SL = Preliminary Peer-Reviewed Toxicity Value Screening Level Obtained from: http://hhpprtv.ornl.gov/
NCEA = National Center for Environmental Assessment:
RSL Users Guide - Regional Screening Levels Users Guide

Prepared By: KMW 11/14/2013
Checked By: BJR 11/21/2013
Revised By: KMW 5/15/14
Checked by: MJM 5/20/14
Revised By: LCG 4/10/2015
Checked by: MJM 4/10/2015

Subchronic RfDs are obtained from:
- PPRTV: provisional value
- ATSDR: Intermitent MRLs
- HEAST: subchronic RfDs
- Equal to chronic RfDs when no PPRTV, ATSDR or HEAST value is available

mg = milligram
kg = kilogram
ND = no data available
chronic = the chronic value is used as the subchronic RfD

(1) Values obtained from RAGS Volume 1 (Part E, Supplemental Guidance for Dermal Risk Assessment, Final) (USEPA, 2004)
Per this guidance, a value of 100% is used for analytes without published values.
(2) Adjusted Dermal RfD = Oral RfD x Oral to Dermal Adjustment Factor. Per RAGS Part E (USEPA, 2004), adjustments are only performed for chemicals that have an oral absorption efficiency of less than 50%.
Surrogates
Surrogate (1) - Value for acenaphthene used as a surrogate
Surrogate (2) - Value for pyrene used as a surrogate
Surrogate (3) - Value for total xylenes used as a surrogate

- ATSDR: Intermitent MRLs
- HEAST: subchronic RfDs
- Equal to chronic RfDs when no PPRTV, ATSDR or HEAST value is available

(1) - Inhalation non-cancer dose-response values are typically published as RfC values. RfC values may be converted to RfDs using the following equation (HEAST, 1997):
RfD (mg/kg-d) = RfC (mg/m^3) x 20 m^3/d / 70 kg, unless otherwise indicated

Surrogate (1) - Value for total xylenes used as a surrogate

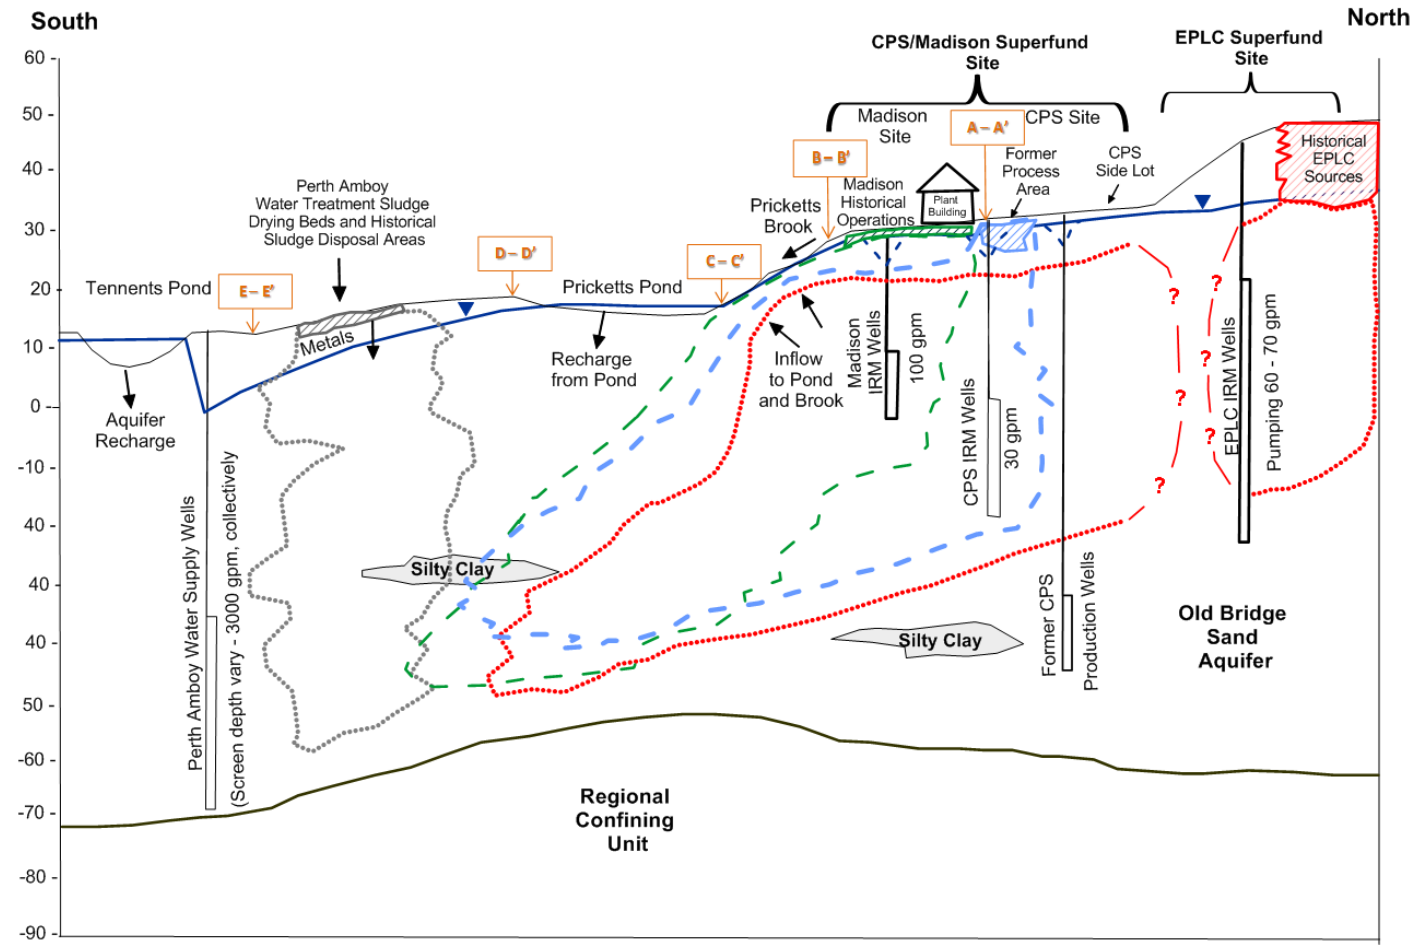
Figure 1-3a showing surface water drainage across the CPS property. Both features support water only during significant storm events and during high groundwater table conditions.

Figure 1-4 - Conceptual Site Model



Legend

*Hatched areas show approximate source areas contributing to groundwater contamination

*Dashed outlines show generated representation of the locations of the dissolved phase contaminant plumes emanating from the source areas

*Potential source areas and plume configurations are shown in red for EPLC (primarily chlorinated VOCs); blue for CPS (primarily benzene, chlorobenzene and 1,2,4-trichlorobenzene) and green for Madison Industries (metals, primarily zinc) impacts

*Approximate locations of plume transect cross-sections are shown (e.g., (E-E'))

Attachment C

GW SW Interaction

This attachment has been included to facilitate review of the BHHRA. In the final RI and BHHRA, the text of the BHHRA will refer to the actual section of the RI Report that discusses the GW/SW Interaction Study. Therefore, this attachment will not be necessary and it will not be included in the final BHHRA.

3.2.3 Task 3: Groundwater/Surface Water Interaction Study (Tier I Evaluation)

The groundwater/surface water interaction study was conducted over 5 days of fieldwork between December 8, 2010 and December 15, 2010. The purposes of this task were to:

- Identify areas of groundwater discharge (upwelling) and stream loss (groundwater recharge) along Pricketts Brook and Pricketts Pond,
- Support a Tier I evaluation of ecological risk by characterizing and comparing sub-streambed groundwater quality at groundwater discharge locations to appropriate Ecological Screening Criteria (defined in Section 3.2.3.2), and
- Assess the potential role of stream sediments as sources of groundwater contamination by characterizing and comparing sub-streambed groundwater quality at groundwater recharge locations to NJDEP GWQS.

Consistent with the Phase 2 FSP and the QAPP, the groundwater/surface water interaction study involved the following activities at each of 14 locations shown on **Figure 10**:

- Installation of a temporary piezometer, Solinst® Model 615N Drive-Point Piezometer, which has a stainless steel, 50 mesh cylindrical filter-screen within a ¾" (20 mm) stainless steel drive-point body.
- Measurement of depths to groundwater within the piezometer and surface water outside the piezometer to allow determination of vertical hydraulic gradient between surface water and groundwater, and
- Collection of groundwater samples from the piezometer
- Validation of the resulting data packages.

Table 2C summarizes piezometer construction, field measurements, sample collection and laboratory analysis performed. There were no significant site access issues, so the field measurements and sampling were conducted at locations corresponding to the planned locations shown in the Phase 2 FSP. As noted in Table 2C, several of the piezometers were installed up to two feet deeper than planned (up to five feet below the top of the sediment), in order to set the piezometer screen below low-permeability surface sediments or iron-cemented soil layers, into the underlying sandy aquifer matrix.

Full analytical results for samples collected during the Groundwater / Surface Water Interaction Study area are presented in tables contained in **Appendix F-3**. Except as noted below, all samples were analyzed for VOCs, SVOCs and total (unfiltered) TAL Metals and dissolved (laboratory filtered) TAL Metals. Analytical methods included EPA Methods 8260 (25 mL purge) and 8011 for VOCs, EPA Method 8270 for SVOCs, and EPA Method 6010B for TAL Metals.

At location GW-SW-4, slow water entry into the temporary piezometer precluded collection of samples for SVOCs and TAL Metals, but samples were obtained for VOCs. Because GW-SW-4 was determined to be a location of groundwater discharge to surface water (see Section 3.2.3.1), CPS-related constituents (i.e., VOCs) are of principal interest at this location. Therefore, the sample data obtained from this point are deemed sufficient to support investigation objectives.

As shown in Table 2C, elevated turbidity persisted at most sampling locations after purging, so it was generally not possible to obtain a low-turbidity (i.e., less than 10 NTU) sample. Therefore, as discussed for the groundwater grab sampling tasks (see Section 3.2.1), total (unfiltered) metals results are non-representative of actual groundwater conditions, overstating metals concentrations. For this reason, dissolved metals values are more appropriate for comparison to surface water quality criteria than are total metals values, and dissolved (filtered) metals data are used to characterize sub-streambed metals concentrations in the Groundwater / Surface Water Interaction Study.

As discussed below, completion of the Groundwater / Surface Water Interaction Study accomplished the SRI Phase 2 objectives for this task. Based on this analysis, the Tier 2 evaluation (Surface Water and Sediment Sampling – Task 4) is not necessary (see Section 3.2.3.3).

3.2.3.1 Hydraulic Head Relationships

Table 3A summarizes hydraulic head relationships and the calculation of the vertical component of hydraulic head between surface water and sub-streambed groundwater at each of the temporary piezometer locations. Vertical hydraulic gradient values are also included on Figure 10, with negative gradient values indicating downward flow potential (stream loss, groundwater recharge) and positive gradient values indicating upward flow potential (stream gain, groundwater discharge).

Results of this assessment indicate that:

- Groundwater recharge (stream loss) occurs along the segment of the stream passing through the Madison Site (study locations GW-SW-1 and GW-SW-2),
- Groundwater discharge (upwelling) occurs along Pricketts Brook downstream of the Madison Site and at the northernmost portion of Pricketts Pond (study locations GW-SW-3 through GW-SW-7), and
- Groundwater recharge (stream loss) occurs along the lower portions of Pricketts Pond and the southern segment of Pricketts Brook downstream of the pond (study locations GW-SW-8 through GW-SW-14 – except for location GW-SW-13, where no vertical flow potential is evident).
- GW-SW-8 is just downgradient of the groundwater discharge zone, which before hydraulic control (1st generation) was a plume discharge zone. The data at this location shows residual contaminant concentrations (below criteria) related to dispersive effects.

This characterization is consistent with previously obtained information (head relationships at permanent monitoring wells, the known purpose of Pricketts Pond as an aquifer recharge feature), and observations made during direct-push groundwater sampling near the Brook (see Section 3.1.5).

3.2.3.2 Findings Relevant to Human and Ecological Receptor Evaluation

Table 3B summarizes all VOC, SVOC and TAL Metals detections at groundwater discharge (upwelling) locations, comparing potential CPS Site-related constituents (VOCs and SVOCs) to appropriate Ecological Screening Criteria. The Ecological Screening Criteria included, in descending order of preference, depending on availability of criteria for specific chemicals:

- NJDEP Ecological Screening Criteria for chronic exposures
- National Ambient Water Quality Criteria for chronic exposures
- Tier II criteria for chronic exposures (described in the EPA's 1993 *Proposed Water Quality Guidance for the Great Lakes System*), or
- National Oceanic and Atmospheric Administration (NOAA) Screening Quick Reference Table (SQuiRT) values for chronic exposures.

Ecological criteria are not included on the Table 3B because, consistent with the 2005 EPA SOW, and as stated in Section 2.2.4, BASF is not responsible for conducting RI/FS activities for metals in media other than groundwater. As such, potential ecological (as well as human) receptor exposures associated with groundwater discharging to surface water and sediments were evaluated for nonmetal constituents only. Consistent with the approved workplan, in Tier 1 of this evaluation, groundwater VOC and SVOC data were used as a surrogate for surface water to determine if the pathway was complete for VOC and SVOC and if so, whether additional assessment was needed for site-specific constituents of concern (VOC and SVOC). The details of the Tier 1 evaluation will be included in the human and ecological risk assessment deliverables. Based on the results from the Tier 1 evaluation, the Tier 2 evaluation is not warranted, and therefore, no additional surface water and sediment sampling was performed.

To evaluate human health risk for surface water, nonmetal screening criteria for recreational users/trespassers were identified using EPA assumptions and equations. The details of the development of these criteria and the criteria are provided in **Table 3C**. As identified in the footnote from Table 3C, recreator parameters used to derive screening values were as follows: EF = 56 d/yr, ED = 12 yrs, Exp. time= 1hr, BW = 48.85 kg, IRwater = 0.05L/hr. Since the screening criteria was based on a recreational user exposed to surface water via dermal contact and incidental ingestion, the parameters used for the dermal portion of the calculation were as follows: EF= 56 d/yr, ED= 12 yrs, Exp. time= 1hr, BW= 48.85 kg, Skin Surface Area = 7,990 cm2 and compound-specific dermal permeability values (Kp).

Applicability of the EPA National Recommended Water Quality Criteria will be evaluated in the Risk Assessment, per surface water body. Some of the surface water bodies are intermittent and

the criteria for fish consumption may not be applicable if the stream cannot support an edible sized fish population.

Based on the hydraulic gradient assessment and the comparison of sub-streambed groundwater quality sampling results presented in Tables 3B and 3C, there are no areas along the Pricketts Brook drainage where analyte concentrations in discharging groundwater exceed the corresponding Human Health or Ecological Screening Criteria for VOCs or SVOCs. Therefore, CPS impacted groundwater discharging to surface water would not likely produce any potential adverse impacts to aquatic or human receptors.

Based on the approved strategy outlined in the Phase 2 FSP, therefore, further investigation along Pricketts Brook and Pricketts Pond (i.e., surface water or sediment sampling) is not required.

3.2.3.3 Groundwater Source Assessment

Table 3D summarizes all VOC, SVOC and TAL Metals detections at groundwater recharge (stream loss) locations, compared to NJDEP GWQS. Based on the hydraulic gradient assessment and the comparison of sub-streambed groundwater quality sampling results presented in Table 3C, there are no groundwater recharge areas along the Pricketts Brook drainage where the recharging groundwater significantly exceeds the GWQS for VOCs or SVOCs. At location GW-SW-1, the chemical 1,2-dichloroethane (1,2-DCA) was detected in the sub-streambed groundwater at a concentration of 3.5 ug/L, which marginally exceeds the GWQS of 2 ug/L. It must be noted that the stream near locations GW-SW-1 and -2 is in a natural groundwater discharge zone, and that the gradient data reflect the apparent effect of pumping from both the CPS IRM (i.e., CPS-3A) and the Madison P&T (i.e., RS-1-series). Therefore, the VOC detections at these two locations are due to their proximity to the CPS source area (dispersive plume edge) and impact from the upgradient EPLC plume (characterized by the presence of 1,2-DCA and cis-1,2-DCE [Ciba 2005, 2008]). Therefore, the stream sediments are not a source of CPS Site-related groundwater contamination. This is consistent with information presented in Section 2.3 of the Phase 2 FSP; transport of CPS Site-related constituents to surface water bodies via surface runoff was precluded for most of the site's operational history by the presence of impermeable surface cover and curbing at the site perimeter.

The following discussion focuses on Madison COIs (copper, cadmium, lead and zinc). Note that other metals detected above GWQS (aluminum, beryllium, iron and manganese) are naturally occurring. Furthermore, pursuant to NJDEP guidance, Impact to Groundwater pathway does not need to be evaluated for secondary parameters (i.e., developed primarily for aesthetic characteristics) including aluminum, iron, manganese, silver and sodium, unless there is cause to believe their presence is due to a site discharge http://www.nj.gov/dep/srp/guidance/rs/igw_faq.pdf. Based on the discussions in Sections 4.2.1 and 4.2.2 of the SCSR, aluminum, beryllium, iron and manganese are not associated with any known or suspected historical sources on either the CPS or Madison properties.

Considering dissolved metals, several, including cadmium, lead and zinc, do exceed GWQS in two areas of the Pricketts Brook drainage way where groundwater recharge takes place. These areas are:

- On the Madison Site at sampling locations GW-SW-1 and GW-SW-2 at the northern end of area investigated during the groundwater / surface water study, and
- On the Runyon Watershed property, adjacent to Perth Amboy's water treatment sludge management areas, at sampling locations GW-SW-12 and GW-SW-14 at the southern end of area investigated during the groundwater / surface water study (GW-SW-13 also had above-GWQS metals results, but the vertical hydraulic gradient at this location was neutral).

On the Madison Site, above-GWQS dissolved metals detections at stream-loss locations were: zinc at GW-SW-1 (20,800 ug/L) and cadmium, lead and zinc at GW-SW-2 (20; 45.4 and 3,550 ug/L, respectively). Because this area is a natural groundwater discharge zone, these detections are likely groundwater-related.

On the Runyon Watershed property, the dissolved metals detections above the GWQS at stream-loss locations were: cadmium at GW-SW-12 and GW-SW-14 (9.5 and 27.6 ug/L, respectively); lead at GW-SW-12 (9.6 ug/L) and zinc at GW-SW-12 and GW-SW-14 (2,240 and 3,560 ug/L, respectively). Because this area is in an induced groundwater recharge area, these detections imply a potential sediment source for metals impact in groundwater (see Sections 4.2.2 and 4.3.3.2 for discussion on the source for metals impact in this region of the aquifer).

3.2.4 Task 4: Surface Water and Sediment Sampling at Selected Locations (Tier II Evaluation)

As described in Section 2.3 of the Phase 2 FSP, transport of CPS Site-related constituents to surface water bodies via surface runoff was precluded for most of the site's operational history by the presence of impermeable surface cover and curbing at the site perimeter. In addition, a sediment study performed by Wehran Engineering in 1983 found no evidence of sediment impact attributable to runoff from the CPS Site only several years after the pavement and curbing were installed, suggesting that any earlier sediment migration from the CPS Site via runoff was either negligible or non-existent.

While impacts on sediment and surface water quality from CPS surface water runoff are not apparent, site investigation data available prior to SRI Phase 2 indicated that groundwater may discharge along portions of the surface drainage downgradient of the site, and thus this exposure pathway needs to be characterized. Accordingly, a tiered approach was developed for evaluating the groundwater to surface water pathway. The Tier I evaluation (Task 3) included characterizing sub-streambed groundwater quality and flow conditions (groundwater discharge or recharge). A subsequent Tier II evaluation of surface water and sediment would be required only if the Tier I

work identified groundwater discharge areas in which sub-streambed groundwater exhibited CPS Site-related constituents above Ecological Screening Criteria.

As discussed in Section 3.2.3, the Tier I evaluation did not identify any groundwater discharge areas in which sub-streambed groundwater exhibited VOCs or SVOCs above Human Health or Ecological Screening Criteria. Therefore, as provided for in Section 4.4 of the Phase 2 FSP, a Tier II Evaluation to address VOCs and SVOCs in surface water and sediment as part of BASF's SRI was determined to be unnecessary.

Based on the above, BASF has fulfilled its responsibility by conducting the Tier I evaluation and does not propose to conduct a Tier II evaluation.

3.2.5 Task 5: Side Lot Area VOC Source Investigation / Background Vanadium Evaluation

BASF completed two activities under Task 5 during Phase 2, to clarify conditions identified during Phase 1 sampling in the CPS Side Lot. These included:

- Groundwater grab sampling to assess the potential presence and extent of a source of VOC impact in the vicinity of SRI Phase 1 sample location CPS-SRI-SS-8, near the eastern, upgradient edge of the Side Lot, and
- Review of published scientific literature and a site-specific statistical evaluation to assess the origin of vanadium in soils on the CPS Side Lot

The Phase 1 and Phase 2 sampling locations are shown on Figure 11. Results of CPS Side Lot VOC source and background vanadium evaluations are discussed below.

3.2.5.1 CPS Side Lot Area Groundwater VOC Source Investigation

The CPS Side Lot VOC source investigation sampling was conducted on January 17, 2011 and January 23, 2011. As shown on **Figure 11**, shallow groundwater samples were collected at 15 locations surrounding, and upgradient of SRI Phase 1 sampling location CPS-SRI-SS-8, where chlorobenzene had been detected at a low-level concentration of 3.2 mg/kg in a soil sample, at or below the water table (3.5 to 4.0 feet below grade). The purpose of the sampling during SRI Phase 2 was to evaluate the potential presence of a source of VOC impact in this area in the eastern portion of the CPS Side Lot.

Table 2D summarizes the sampling and laboratory analysis performed. There were no significant site access issues, so the sampling was conducted at locations corresponding to the planned locations shown in the Phase 2 FSP. Full analytical results for samples collected during the CPS Side Lot VOC Source Investigation are presented in **Appendix F-4**. Except as noted below, all samples were analyzed for VOCs by EPA Methods 8260 (25 mL purge) and 8011 (for low-level DBCP and EDB characterization).

Table 2C
Sampling and Analysis Summary - SRI Phase 2
Groundwater / Surface Water Interaction Study (Phase 2 Task 3)

CPS/Madison Superfund Site
Old Bridge, New Jersey

Location	Sample ID (with depth)	Date(s) Completed	Coordinates		Boring Total Depth (feet-below sediment surface)		DTW GW (TOC)	DTW SW (TOC)	TOC to Stream Bottom (TOC)	Analyses				Metals Sample Turbidity	Unit at Sampling Depth	Volume Purged (Gallons)	Notes

Notes:
ug/L - microgram per liter
ELCR - Excess Lifetime Cancer Risk
HI - Hazard Index
Screening criteria based on a recreational user exposed to surface water via dermal contact and incidental ingestion with the following parameters:
Exposure Frequency - 56 days per year, Exposure Duration - 12 years, Exposure Time - 1 hour, Body Weight - 48.85 kilograms, Ingestion Rate of Water - 0.05 liters per hour.
Toxicity values were selected using the hierarchy in "Human Health Toxicity Values in Superfund Risk Assessments" OSWER No. 9285.7-53, December 2003.

Prepared By/Date: EYM 09/21/2012
Checked By/Date: SDM 9/26/11

1.0 INTRODUCTION

This Vapor Intrusion (VI) Investigation Report was prepared by MACTEC Engineering and Consulting, Inc. (MACTEC) on behalf of CIBA Specialty Chemicals (CIBA) to document the results of on-site VI investigation activities at the CPS/Madison Superfund Site (Site). These investigation activities were carried out in accordance with the CPS On-Site Vapor Intrusion Investigation Work Plan, CPS/Madison Superfund Site, Old Bridge Township, Middlesex County, New Jersey, submitted May 14, 2009 and approved by e-mail from the United States Environmental Protection Agency (USEPA) on June 3, 2009. This report details the results of the on-site investigation conducted at the CPS property. Results of the off-site investigation conducted at the Madison facility are being reported under separate cover. The Site is a former solvent recovery/chemical processing/chemical manufacturing facility that is currently unoccupied and is located on Old Waterworks Road in Old Bridge Township, Middlesex County, New Jersey.

This report presents results of VI investigation activities including sub-slab soil gas and indoor air sampling and analysis completed during September 2009. Work included sampling within the laboratory, office and warehouse portions of the building and submittal of samples for laboratory analysis of volatile organic compounds (VOCs). Sampling results were evaluated with respect to the applicable New Jersey Department of Environmental Protection (NJDEP) Soil Gas Screening Levels (SGSLs), Indoor Air Screening Levels (IASLs), and the NJDEP Decision Flow Chart for the VI Pathway (NJDEP 2005a).

Based on the findings as discussed herein, the VI pathway is not complete, and no further investigation is warranted at this time.

Site background information is provided in Section 2. The VI investigation work and results are discussed in Section 3. A summary of findings and recommendations is presented in Section 4.

2.0 SITE BACKGROUND

2.1 ENVIRONMENTAL SETTING

The Site location is shown in Figure 1. A brief summary of Site geology, Site hydrogeology, and Site topography are presented below (CIBA, 2008).

Geology:

The CPS Site lies in the northeastern part of the Coastal Plain Physiographic Province which consists of a large, regional wedge of unconsolidated and poorly-consolidated sands, gravels, silts and clays. The depth to the top of bedrock near the CPS Site is approximately 270 to 300 feet below ground surface (ft-bgs).

At the CPS Site, the Old Bridge Sand, a member of the Cretaceous-age Raritan Formation, occurs from just below ground surface to 55 ft-bgs. The Old Bridge Sand is primarily a fine- to coarse-grained, well-sorted sand with occasional, discontinuous, thin beds of clay. Locally, a veneer of the Quaternary-age Cape May Formation overlies the Old Bridge Sand. The two units are lithologically similar and are in direct hydraulic connection.

The Old Bridge Sand is underlain by the South Amboy Fire Clay. Where present, the South Amboy Fire Clay is found at a depth varying from 55 to 85 ft-bgs. The clay was found to be thin or absent beneath portions of the CPS and Madison sites. Underlying the South Amboy Fire Clay is a thin layer of the Sayreville Sand, which has a composition similar to the Old Bridge Sand. The laterally continuous Woodbridge Clay with an average thickness of about 100 ft lies beneath the Sayreville Sand and is the confining unit between the Old Bridge Sand and Farrington Sand aquifers. The underlying Farrington Sand is a fine- to medium-grained unit of variable thickness.

Hydrogeology:

The Cape May, Old Bridge and Sayreville Sand units comprise the Old Bridge water-table aquifer at the CPS facility and the Runyon Well Field. The South Amboy Fire Clay is a confining unit existing within the Old Bridge aquifer, but is not laterally continuous. The Woodbridge Clay, a continuous confining unit with a thickness of about 100 ft, separates the Old Bridge Sand and Farrington Sand aquifers. The Farrington Sand is also a major regional aquifer.

Based on local aquifer pumping tests, the average hydraulic conductivity (K) of the Old Bridge aquifer in the vicinity of the CPS Site ranges from approximately 74 to 100 ft/day, and the effective porosity is approximately 40 percent. Storage values range from 0.02 to 0.05, which are typical for unconfined aquifers containing clay layers.

Ground water levels are shallow, encountered from approximately 6 to 10 ft-bgs in monitoring wells located on and downgradient of the CPS Site. Water level fluctuations are coincident with precipitation events due to the permeable recharge characteristics of the ground surface.

Ground water elevation contours indicate a southwest flow direction under both static and pumping conditions. The hydraulic gradient of the water table appears to be consistent and relatively flat at an average value of 0.004 foot/foot. Water table levels measured adjacent to Pricketts Pond indicate that ground water from the north discharges into the pond; to the south the pond appears to recharge the aquifer.

Based on ground water data collected at the CPS Site, the flow direction and hydraulic gradient are similar to the regional values.

Topography:

Regional topography around the CPS Site is relatively flat with little natural relief. The land surface elevation is approximately 25 ft above mean sea level (ft-msl). Local topography slopes gently to the south and southwest, towards Pricketts and Tennent Ponds.

2.2 SITE CONCEPTUAL MODEL – POTENTIAL EXPOSURE PATHWAYS

A Site conceptual exposure model was developed based on the Site conditions, fate and transport characteristics of the Site-related contaminants, mechanisms of toxicity of Site-related contaminants, and potential receptors. A complete exposure pathway is defined as one in which the Site-related constituents can be traced or expected to travel from the source to a receptor that can be affected by each contaminant. If any of these conditions are missing, the pathway is considered to be incomplete. An ecological exposure pathway is considered incomplete if habitat is not present. Potential complete exposure pathways at the Site include potential direct contact with contaminated soils or groundwater or vapor exposure by construction workers and potential for indoor air quality impacts via subsurface vapor transport. Potential exposure pathways were evaluated as follows.

Vapor Transport

Exposure to indoor air impacted by vapor intrusion from groundwater and/or subsurface soil into buildings is recognized as a potential human health risk, particularly where volatiles are present in water table ground water, in subsurface soil, or where free product or non-aqueous phase liquid (NAPL) is present. Federal and state regulatory requirements and guidance (USEPA, 2001, 2002, 2004, NJDEP, 2005a, 2005b, 2006) for evaluation of indoor air list three major techniques or tools for assessing vapor intrusion impacts to indoor air: vapor transport modeling (including the Johnson and Ettinger Vapor Intrusion Model (Johnson & Ettinger, 1991) with numerous technical updates); Soil Gas Sampling; and Indoor Air Monitoring.

Based on the Remedial Investigation (RI) data, VOC-impacted groundwater appears to be limited to the main process area of the CPS Site. Hydropunch and ground water sampling have isolated the most VOC-impacted area to the southern portion of the main process area and Tank Farms 1 through 5. The "hotspot" of the contaminant plume is directly south of the CPS building, with an extent (west to east) of less than 140 ft. The full areal extent of the impact area above maximum contaminant levels (MCLs) is shown in Appendix A. Groundwater at the Site tends to flow in an approximately southwestern direction, and the plume in general moves away from the CPS building. However, Site related contaminants have been found in one well (WCC-1M) located northeast of the CPS building (see section 2.3 for more details). The vertical distribution of contaminant compounds is based primarily on hydropunch sampling data. In general, total VOC concentrations were highest at the water table and decreased with depth. The vertical extent of the hotspot is approximately 40 ft-bgs, but may extend to depths up to 90 ft-bgs. Quarterly groundwater sampling was performed during 2007, and groundwater sample results were reviewed for an initial evaluation of vapor intrusion pathway (see Section 2.3). Additional VI investigation was completed during 2009 and is the subject of this report.

2.3 GROUNDWATER SAMPLING RESULTS

Ground water sampling is conducted quarterly at the Site as part of the Performance Monitoring Program (PMP). In June 2007, CIBA performed work that included a round of water level measurements and sampling of 26 wells. Results of that sampling event will be used to evaluate the VI pathway. The most recent PMP report was submitted in September 2007 for the First and Second Quarter 2007.

Ground water data indicate that chlorinated solvents are the primary contaminants of concern (COCs) for the potential on-site vapor intrusion pathway, consistent with previous RI results. Another on-site COC is benzene. The constituents identified in **Table 1** were detected in monitoring wells at concentrations above the current NJDEP Groundwater Screening Levels (GWSLs) for vapor intrusion in the second quarter 2007. For non-detects, reporting limits that are above the GWSLs are included as a conservative measure.

Ground water sample results for the primary Site-related constituents of concern detected above the NJDEP Groundwater Quality Standards (GWQS) and the GWSL (where applicable) are included in **Appendix A**. Site-wide ground water level measurements indicate that the average depth to the ground water table ranged from approximately 5.6-9.6 ft-bgs, during 2007. Depth to ground water beneath the building (warehouse and office/laboratory space) appears to be approximately 2.5 ft. Based on the June 2007 measured ground water contour, the on-site subject structure is upgradient of the highest ground water contaminant concentration, but within the area of the delineated plume. One well, WCC-1M is upgradient of the building with VOC (1,2-Dichloroethane [1,2-DCA] and trichloroethylene [TCE]) detections above the GWSL. Although the detected exceedances are at a distance of 280 ft from the building, which is greater than the NJDEP recommended screening criteria of 100 ft, further evaluation of the VI pathway was determined to be warranted based on the interpolated extent of the groundwater plume above MCLs (see Appendix A). Further assessment of the VI pathway has been evaluated through the use of concurrent and co-located sub-slab soil gas and indoor air sampling and is the subject of this report. As required by NJDEP, ambient air sampling was also conducted.

Ground water sample results and elevation data for samples collected during the first and second quarter 2007 were included in the VI Work Plan. Complete results for the on-site ground water investigation were transmitted to the USEPA and NJDEP (CIBA, 2007). Groundwater sample results for VOCs exceeding both the NJDEP GWQSs and GWSLs are indicated on tables and figures in Appendix A.

3.0 VAPOR INTRUSION INVESTIGATION AND RESULTS

3.1 TECHNICAL OVERVIEW

The on-site VI investigation was conducted in accordance with the VI Work Plan that was submitted May 14, 2009 and approved by the NJDEP in an e-mail dated June 3, 2009. The work activities completed and discussed in this section are summarized below:

- Site-walk to determine appropriate sampling locations;
- Field mobilization including utility mark-out/geophysical survey to verify the absence of underground utilities at proposed drilling and sample locations;
- Collection of soil gas and indoor air samples and submittal of samples for laboratory analyses of VOCs using Method TO-15; and,
- Data evaluation of results with respect to applicable regulatory criteria.

Field sampling activities during September 2009 included sub-slab and indoor air sampling within the office, laboratory, and warehouse portions of the building (4 sample locations). In addition, three (3) background ambient air samples were collected as part of the sampling program. Two of the background samples were collected from inside the building, one in each of the stairwell landings, and the third background sample was collected outside and upwind of the building location.

Field sampling and laboratory analysis was performed in accordance with the work plan and applicable protocols contained in the NJDEP Vapor Intrusion Guidance Document (October 2005) and Field Sampling Procedures Manual (August 2005). Sub-slab soil gas and indoor air samples were conducted concurrently along with ambient air sampling to provide data on potential background sources of contamination. Indoor air samples were collected first (Day 1) followed by installation of permanent probes and collection of sub-slab samples (Days 2 and 3) to avoid potential contribution or interferences from the sub-slab soil sampling operations on the indoor air samples. Photographs of sample locations and sampling devices are presented in **Appendix B**.

All samples were submitted to Accutest Laboratories (Accutest) of Dayton, New Jersey for analysis of VOCs using Method TO-15. The sampling and laboratory analytical program included applicable quality assurance/quality control requirements specified in the NJDEP VI Guidance and the analytical method, including completion of TO-15 field test data sheets, clean canister

certification, method blanks, instrument blanks, and laboratory control samples. Laboratory analytical reports are included in **Appendix C**. Copies of all chains of custody are included in the laboratory reports. Data validation was performed by CIBA and results indicate that laboratory analytical data is acceptable for use with minor qualifications. Some sample results for methylene chloride were negated due to the presence of this compound in the laboratory method blank. Data validation summary reports will be included in the Final Supplemental RI Report.

The sampling program is summarized on **Table 2**. Indoor air and sub-slab soil gas sample results for the September 2009 investigation are presented in **Tables 3 and 4**, respectively. A summary of detected VOCs is presented in **Table 5**. Sample results exceeding applicable screening levels are indicated on **Figure 2**.

Sampling activities and results are discussed in Sections 3.2 and 3.3. A summary of findings and recommendation is presented in Section 4. Based on the VI investigation results, the vapor intrusion pathway was judged to be incomplete and no further investigation or action is recommended.

3.2 FIELD MOBILIZATION AND SAMPLING

Field mobilization began on September 15th and sampling was completed September 17th, 2009. During this time frame additional samples were collected at the adjacent Madison facility as part of the off-site vapor intrusion work plan; results of the off-site investigation are being submitted under separate cover. Activities for the on-site VI investigation included:

- review of the Site's Health and Safety Plan (HASP) and field mobilization including utility mark-out/geophysical survey to verify the absence of underground utilities at proposed intrusive drilling locations;
- collection of soil gas samples and indoor air samples as well as ambient or outside air samples using Summa canisters at selected locations; and
- submittal of samples for laboratory analysis of VOCs.

A preliminary building inspection was performed on January 30, 2008 to identify sample locations and support work plan preparation. The building evaluation included completion of the NJDEP Indoor Air Building Survey and Sampling Form. The building is currently unoccupied and the Heating, Ventilation, and Air Conditioning (HVAC) is being operated at a minimum level to

prevent cold weather damage. The building inspection addressed the following items consistent with NJDEP VI guidance:

- determination and analysis of building construction;
- analysis of potential background sources of VOCs;
- identification of potential VI pathways into a structure and possible sampling locations; and,
- review of VI sampling procedures with building occupants/owners.

The building is slab-on grade construction (6 to 8-inch thick concrete) and is divided into a 2 floor administration/laboratory and a single-story warehouse (see Figure 2). The office portion is located nearest to the groundwater impacts at the northeast corner of the building and has carpeted flooring. The laboratory has vinyl floor tiles and multiple floor drains that are connected to the sanitary sewer. The warehouse area has a concrete floor and is used for storage of small gas powered equipment and chemicals associated with the groundwater treatment system, including TOLCIDE (an industrial antimicrobial), metafloc-c, FeREMEDE, and calcium chloride.

3.3 SOIL GAS AND INDOOR AIR SAMPLING – SEPTEMBER 2009

This section summarizes the sub-slab soil gas and indoor air sample collection and analysis as well as the evaluation of the associated analytical data.

3.3.1 Sampling and Analysis

Indoor air samples were collected (following the procedures specified in the NJDEP VI Guidance and the Field Sampling Procedures Manual (NJDEP, 2005b)) by MACTEC using laboratory supplied 6-Liter stainless steel canisters over a 24-hour period during September 15-16, 2009. Weather observations during that period of time indicate that the temperature ranged from 16.1-18.8 degrees Celsius (°C), no precipitation was observed and barometric pressure was at 30.27 in mercury (Hg). Indoor air samples were co-located within the same building spaces as sub-slab soil gas samples and collected from breathing zone height (3 to 5 ft). Three (3) background air samples were collected, 2 were located within the 2nd floor stairwell landings and one was located upwind of the building along the southeastern site boundary. Indoor and outdoor air samples were transferred, under chain of custody, to Accutest Laboratories in Dayton, New Jersey. Samples were analyzed for VOCs using USEPA Method TO-15. Field Data Records and field logs are included in **Appendix D**.

Immediately following collection of indoor air samples and removal of canisters from building spaces, permanent sub-slab soil gas probes were installed on September 16-17, 2009 and samples were collected September 17, 2009. During the soil gas sampling temperature was recorded at 15 °C and barometric pressure at 30.30 in Hg, no precipitation was observed during this period of time. A summary of collected sub-slab soil gas, indoor air, and outdoor air samples is presented in Table 2.

Locations of sub-slab soil gas samples, indoor air samples, and outdoor samples are identified in Figure 2. Soil gas samples were collected using direct-push equipment and permanent soil vapor probes in accordance with the work plan, and the NJDEP VI Guidance (NJDEP, 2005a) and the Field Sampling Procedures Manual (2005b). Drilling and soil vapor sampling equipment was provided by TPI Environmental, Inc. with field oversight and sample collection by MACTEC. Concrete coring equipment was used to provide access for probe installation. Field observation indicated that the concrete slab ranged from 6-8” in thickness. Boreholes were advanced approximately 1 ft below slab and permanent probes were set in place at this depth, with the exception of sample point SG-03, which was installed directly below slab due to a high water table at this location. Permanent soil gas probes were constructed from 6” double screened stainless steel vapor sampling implants that were packed in sand, sealed with bentonite, and fitted with 3” aluminum flush mounts that were set in place with concrete.

Prior to soil gas sample collection, the annular seal of each sampling point was tested for leaks using an inert trace compound (helium) to verify the integrity of the seal and confirm no surface air short-circuiting of the sampling point. Helium trace gas was not detected during the sampling activities indicating that all sampling points were effectively sealed. Each sampling point was purged of approximately 3 volumes of air using a purge rate <200 milliliters per minute (ml/min), prior to sample collection. Soil gas samples were collected using laboratory-supplied, stainless steel, 1-Liter Summa canisters using a flow rate of approximately 33 ml/min (sample time 30 minutes). At location SG-03, a duplicate sample was collected using a Y fitting and a flow rate set to one-half the flow of the field sample canisters (sample time 1 hour), thus ensuring that the combined flow rate was equal to the flow of one field sample. All samples were submitted, under chain of custody, to Accutest Laboratories for laboratory analysis of VOCs using USEPA Method TO-15.

3.3.2 Data Evaluation

Data were evaluated with respect to the NJDEP SGSLs and IASLs (as applicable) to determine the need for further investigation or action in accordance with NJDEP VI Guidance and Decision Matrix Flow Chart. Indoor air sample results were also evaluated with respect to the Rapid Action Levels (RALs) to determine the need for any immediate action. The indoor and background air and sub-slab soil gas sample results for the September 2009 sampling event are presented in Tables 3 and 4, respectively. A summary of detected VOCs is presented in **Table 5**. Sample results above the SGSLs and/or IASLs (as applicable) are indicated on Figure 2. Other data evaluation factors included the relative exceedance of the screening level, the presence and concentration of VOCs in sub-slab soil gas and indoor air samples, background sample results and possible effects of background contamination sources.

No VOCs were detected above the RALs. VOCs detected in soil gas samples above SGSLs included benzene, chloroform, and tetrachloroethene (warehouse); and chloroform (administrative/laboratory). Of those constituents none were detected in indoor air samples above the IASL in the warehouse or laboratory/administrative areas. In addition, while not detected in soil gas samples, methyl tert butyl ether (MTBE) was detected at a concentration of 1.1 parts per billion-volume (ppbv) in indoor air sample IA-01 (located in the warehouse), slightly above the IASL of 1.0 ppbv. MTBE was also detected in one of the background air samples, but at a concentration below the IASL. These results suggest that MTBE detections in indoor air samples may be associated with building operations or other sources rather than a subsurface source. No VOCs were detected in both soil gas and indoor air samples above applicable screening levels.

Background Samples: Background air sample results indicate that low levels of VOCs (mainly <1 ppbv) were detected in all three background samples, with generally good correlation with respect to compounds and concentrations. VOCs detected in background samples included: 2-butanone, acetone, benzene, chloromethane, dichlorodifluoromethane, methyl ethyl ketone, methylene chloride, toluene, and trichlorofluoromethane.

Laboratory analytical summary reports for the September 2009 sampling event are provided in Appendix C.

4.0 SUMMARY OF FINDINGS AND RECOMMENDATIONS

4.1 FINDINGS

Sub-slab soil gas and indoor air sample data were evaluated with respect to the NJDEP SGSLs and IASLs (as applicable) to determine the need for further investigation or action in accordance with NJDEP VI Guidance and Decision Matrix Flow Chart. Indoor air sample results were also evaluated with respect to the RALs to determine the need for any immediate action. Other factors in the data evaluation included the relative exceedance of the screening level, the presence and concentration of VOCs in sub-slab soil gas and indoor air samples, background sample results and possible effects of background contamination sources. The findings can be summarized as:

- VOCs were not detected above the NJDEP RALs in any of the indoor air samples.
- No VOCs were detected above applicable screening levels in both the sub-slab soil gas and indoor air samples. Some VOCs were detected above SGSLs in soil gas samples (i.e., chloroform, tetrachloroethene, and benzene) but were not detected in indoor air samples, indicating that the VI pathway is not complete for these compounds.
- VOC concentrations in all indoor air samples were below the IASLs, with the exception of the MTBE concentration in IA-01. This exceedance is likely associated with background or other sources, such as the gas powered equipment stored in this area of the warehouse. MTBE was not detected in the associated soil gas sample, indicating that this compound is not attributable to the VI pathway.

4.2 RECOMMENDATIONS

Consistent with the NJDEP Vapor Intrusion Guidance, multiple lines of evidence were evaluated to determine appropriate action for the VI pathway. Based on the VI investigation findings and review of data with respect to NJDEP screening levels and VI Guidance/Decision Flow Chart, there is no immediate adverse health risk or rapid response action required at this time.

Based on the lack of correlation of soil gas and indoor air results, and potential contribution from other sources (i.e., gas powered equipment), no further action is recommended for the on-site VI investigation.

Notes:
IASLs - Indoor Air Screening Levels
SGSLs - Soil Gas Screening Levels
na: not available (no NJDEP criteria established)
Bold/Underlined results exceed relevant Vapor Intrusion Screening Level
Qualifiers:
U - Not detected above MDL
J - Indicates an estimated value
E - Indicates value exceeds calibration range
B - Indicates analyte found in associated method blank
N - indicates presumptive evidence of a compound

Notes:
IASLs - Indoor Air Screening Levels
SGSLs - Soil Gas Screening Levels
na: not available (no NJDEP criteria established)

Prepared By: : EMJ
Checked By: MWV

Qualifiers:
U - Not detected above MDL
J - Indicates an estimated value
E - Indicates value exceeds calibration range
B - Indicates analyte found in associated method blank
N - indicates presumptive evidence of a compound

Table 5
Summary of Detected Constituents in Soil Gas and Indoor Air Samples
On-Site Vapor Intrusion Investigation Report
CPS/Madison Superfund Site
Old Bridge, NJ

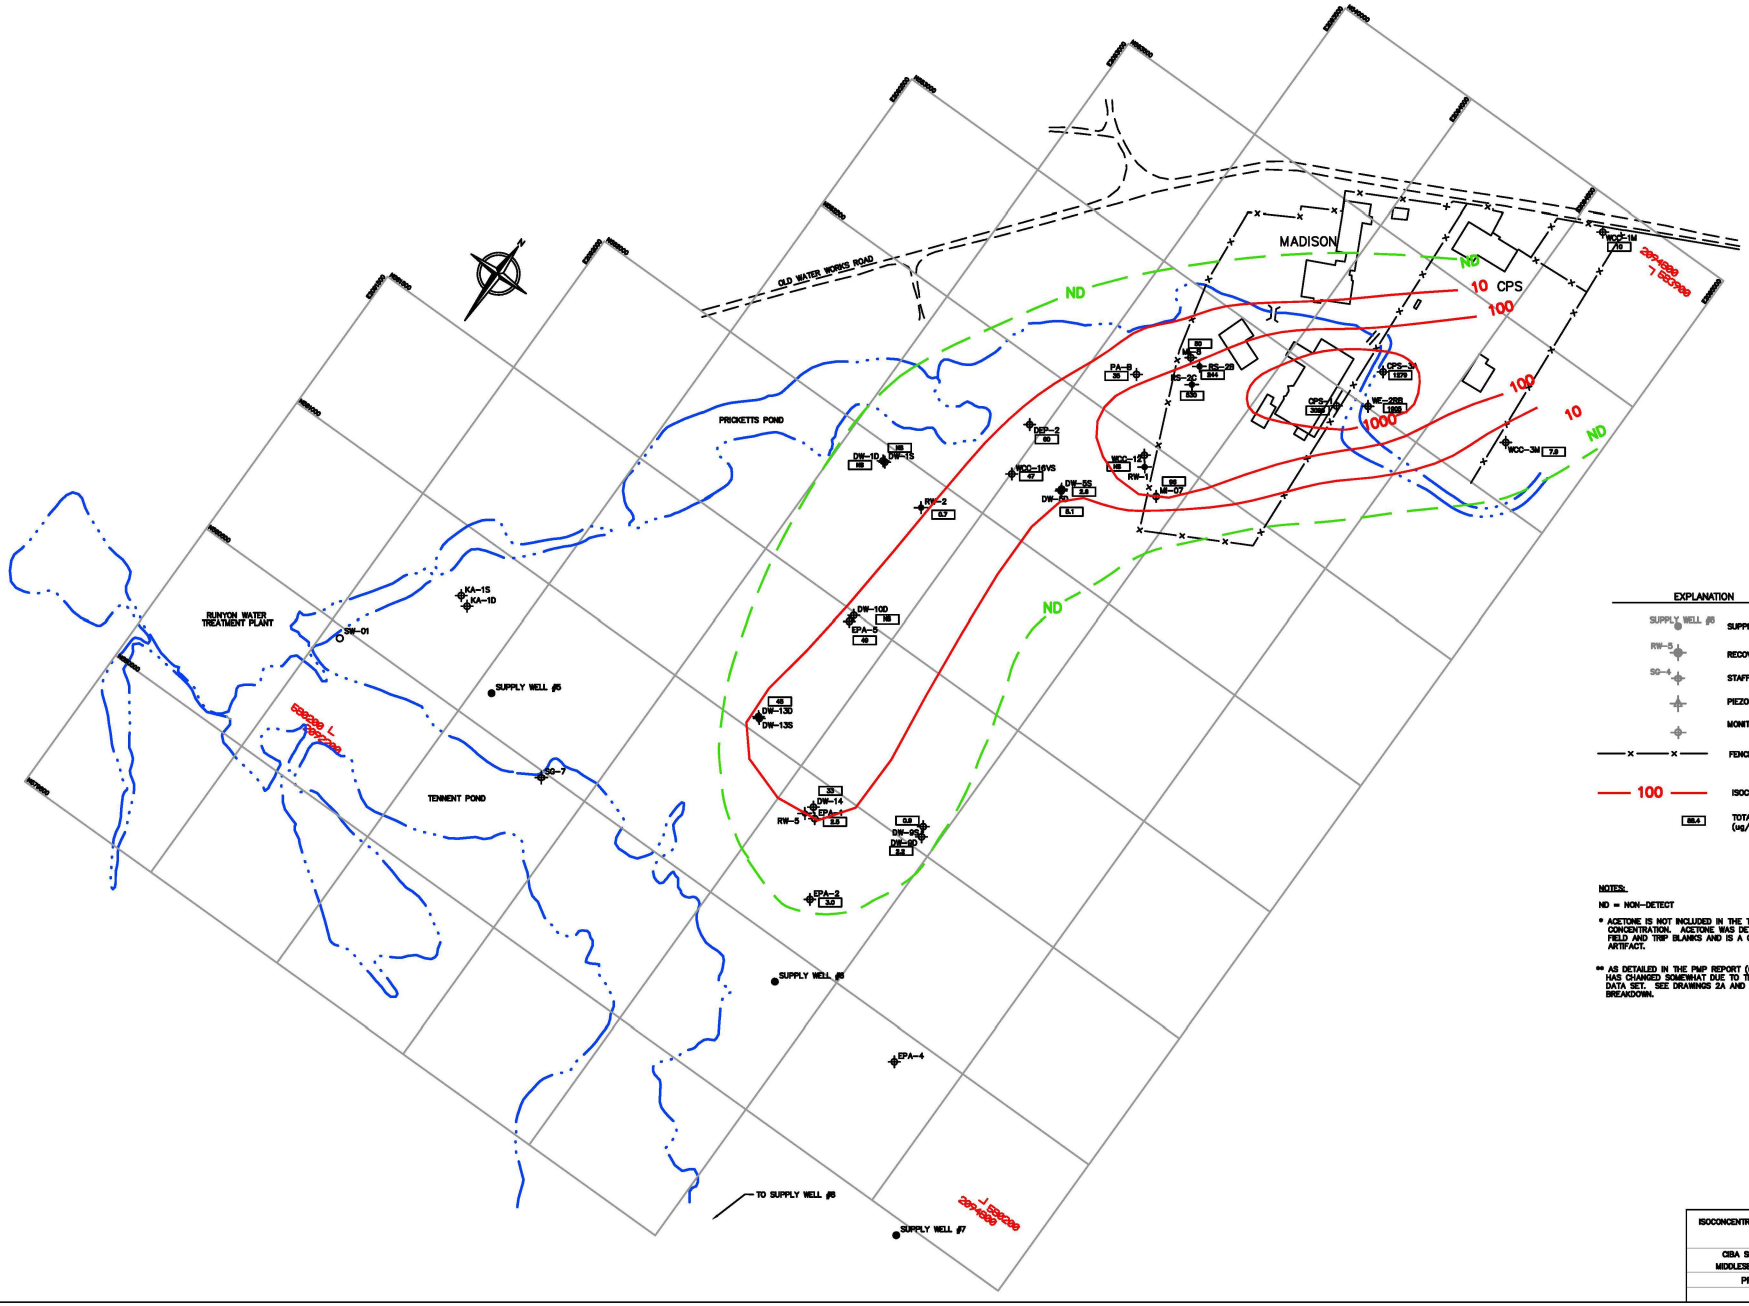
APPENDIX A

REFERENCE DATA
PREVIOUS GROUNDWATER CONTOURS AND SAMPLE RESULTS



EXPLANATION

- SUPPLY WELL #6 — SUPPLY WELL
- RW-5 — RECOVERY WELL
- SG-4 — STAFF GAUGE
- PIEZOMETER
- MONITORING WELL
- FENCE LINE
- 100 — ISOCONCENTRATION CONTOUR
- 88.4 — TOTAL VOLATILE CONCENTRATION* (ug/l)

NOTES:

ND = NON-DETECT

* ACETONE IS NOT INCLUDED IN THE TOTAL VOLATILE CONCENTRATION. ACETONE WAS DETECTED IN THE FIELD AND TRIP BLANKS AND IS A COMMON LABORATORY ARTIFACT.

** AS DETAILED IN THE FMP REPORT (03/04) THE PLUME DELINEATION HAS CHANGED SOMEWHAT DUE TO THE INCLUSION OF MBTE INTO THE DATA SET. SEE DRAWINGS 2A AND 2B FOR THE CONSTITUENT BREAKDOWN.

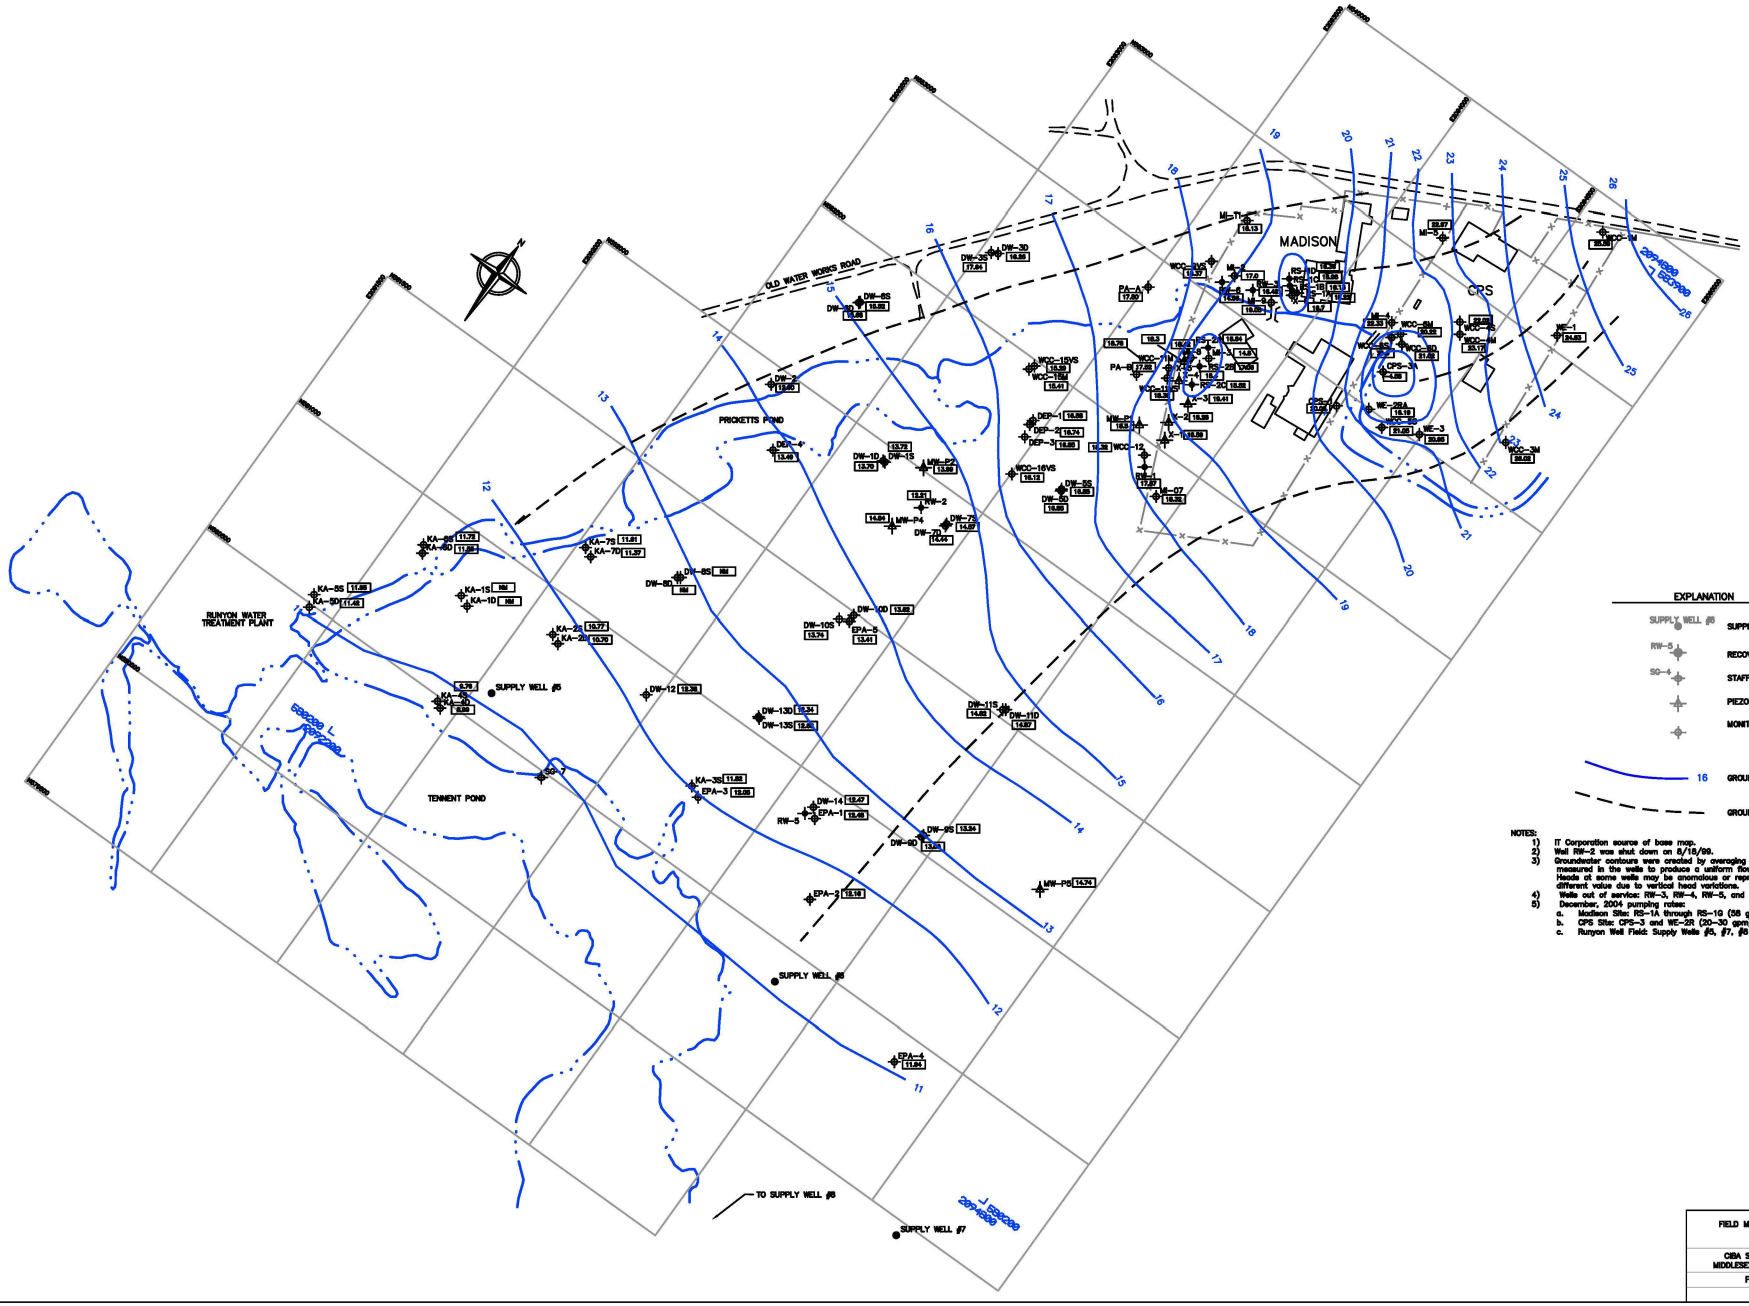
BASED ON EXCEEDANCE OF MCLs
JUNE 2007

CIBA SPECIALTY CHEMICALS CORPORATION
MIDDLESEX COUNTY, OLD BRIDGE, NEW JERSEY

PREPARED AUGUST 2007
FIGURE: 2B



NOTES:

1) IT Corporation source of base map.
2) Well RW-2 was shut down on 6/18/99.
3) Groundwater contours were created by averaging the hydraulic heads measured in the wells to produce a uniform flow across the site. Heads at some wells may be anomalous or represent a slightly different value due to vertical head variations.
4) Wells out of service: RW-3, RW-4, RW-5, and RW-6.
5) December, 2004 pumping rates:
   a. Madison Site: RS-1A through RS-1G (55 gpm); RS-2B and -C (20 gpm)
   b. CPS Site: CPS-3 and WE-2R (20-30 gpm)
   c. Runyon Well Field: Supply Wells #5, #7, #8 and the Rainy Well (5,200 gpm)

CASE NARRATIVE / CONFORMANCE SUMMARY

Client:	Mactec	**Job No**	JA28238
Site:	CPS/Madison Superfund Site, Waterworks Road, Old Bridge, NJ	**Report Date**	10/16/2009 3:08:47 P

On 09/17/2009, 13 Sample(s), 0 Trip Blank(s) and 0 Field Blank(s) were received at Accutest Laboratories. Samples were intact and properly preserved, unless noted below. An Accutest Job Number of JA28238 was assigned to the project. Laboratory sample ID, client sample ID and dates of sample collection are detailed in the report's Results Summary Section.

Specified quality control criteria were achieved for this job except as noted below. For more information, please refer to the analytical results and QC summary pages.

Volatiles by GCMS By Method TO-15

Matrix: AIR **Batch ID:** V2W1083

- All samples were analyzed within the recommended method holding time.
- All method blanks for this batch meet method specific criteria.
- Sample(s) JA28271-5DUP were used as the QC samples indicated.
- Blank Spike Recovery(s) for Tetrahydrofuran are outside control limits. High percent recoveries and no associated positive found in the QC batch.

Matrix: AIR **Batch ID:** V2W1084

- All samples were analyzed within the recommended method holding time.
- All method blanks for this batch meet method specific criteria.
- Sample(s) JA28598-2DUP were used as the QC samples indicated.
- RPD(s) for Duplicate for trans-1,2-Dichloroethylene are outside control limits for sample JA28598-2DUP. High RPD due to low concentration of hit

Matrix: AIR **Batch ID:** V2W1086

- All samples were analyzed within the recommended method holding time.
- All method blanks for this batch meet method specific criteria.
- Sample(s) JA28739-1DUP were used as the QC samples indicated.
- Sample(s) JA28238-7 have compounds reported with "E" qualifiers indicating estimated value exceeding calibration range.

Accutest certifies that data reported for samples received, listed on the associated custody chain or analytical task order, were produced to specifications meeting Accutest's Quality System precision, accuracy and completeness objectives except as noted.

Estimated non-standard method measurement uncertainty data is available on request, based on quality control bias and implicit for standard methods. Acceptable uncertainty requires tested parameter quality control data to meet method criteria.

Accutest Laboratories is not responsible for data quality assumptions if partial reports are used and recommends that this report be used in its entirety. Data release is authorized by Accutest Laboratories indicated via signature on the report cover

Instrument Performance Check (BFB)

Job Number: JA28238
Account: HLANJPR Mactec
Project: CPS/Madison Superfund Site, Waterworks Road, Old Bridge, NJ

Sample: V3W523-BFB
Lab File ID: 3W12850.D
Instrument ID: GCMS3W
Injection Date: 10/02/09
Injection Time: 19:06

m/e	Ion Abundance Criteria	Raw Abundance	% Relative Abundance		Pass/Fail
50	8.0 - 40.0% of mass 95	4462	18.7		Pass
75	30.0 - 66.0% of mass 95	12055	50.4		Pass
95	Base peak, 100% relative abundance	23920	100.0		Pass
96	5.0 - 9.0% of mass 95	1743	7.3		Pass
173	Less than 2.0% of mass 174	0	0.0	(0.0) [a]	Pass
174	50.0 - 120.0% of mass 95	25045	104.7		Pass
175	4.0 - 9.01% of mass 174	1800	7.5	(7.2) [a]	Pass
176	93.0 - 101.0% of mass 174	24549	102.6	(98.0) [a]	Pass
177	5.0 - 9.0% of mass 176	1618	6.8	(6.6) [b]	Pass

(a) Value is % of mass 174
(b) Value is % of mass 176

This check applies to the following Samples, MS, MSD, Blanks, and Standards:
